This book is divided into four parts, each focusing on a particular type of congenital deformity. Parts I and II focus, respectively, on primary and deferred corrective procedures for unilateral and bilateral cleft lip and nose reconstruction. These sections are primarily concerned with improving the child's appearance. Part III deals with cleft palate reconstruction and pharyngeal-flap procedures. This section details surgical techniques aimed at restoring the function of the palate in speech production—without producing iatrogenic facial deformities. Two types of transverse pharyngeal-flap surgery are described in this section. Part IV deals with some unusual cleft problems and three case studies in long-term cleft reconstruction.

Considers the total perioperative picture

With 25 years of practice and more than 2500 cleft operations to his credit, the author brings a wide range of experience and an authoritative viewpoint to this work. From a concentration on techniques that require fewer staged procedures, to methods of suturing the skin, to the use of long-acting local anesthetics even with general anesthesia—you'll find a multitude of suggestions for pre- and postoperative care and interoperative planning that aim to ease the strain on children enduring multiple surgical procedures.

Management of Head and Neck Cancer
A Multidisciplinary Approach

Flexible and innovative therapies for the management of cancer patients

Management of Head and Neck Cancer: A Multidisciplinary Approach

Edited by Rodney R. Million, M.D., and Nicholas J. Cassisi, M.D.
20 Contributors.

". . . a superb volume on head and neck cancer that will at once become the standard of reference . . . comprehensive, with 36 chapters ranging from the history of diagnosis and treatment of head and neck cancer . . . to such modern-day concerns as costs in management of these cancers. In style and format, in illustration and graphics, and particularly in the overall connectedness of the whole, the authors and publisher have produced a work sure to become a classic."—*The Journal of the American Medical Association* ***684 Pages. 941 Illustrations, including 43 in Full Color. 232 Tables. 1984. $99.50.***

WE HAVE ONLY GOOD THINGS TO SAY ABOUT CANCER OF THE COLON.

If detected early, the cure rate for colorectal cancer is very high. It can be as high as 75%.

Because we now know how to detect it early. And we know how to fight it once we detect it.

There are three simple checkup guidelines for men and women without symptoms.

One, get a digital exam every year. This is recommended for everyone over 40.

Two, get a stool blood test every year if you are over 50.

Three, after two initial negative tests one year apart, get a procto exam every three to five years if you are over 50.

These guidelines are the best protection against colorectal cancer you can have.

If you're not over 50, please give this information to friends and loved ones who are.

In any case, please help spread the word.

Good news doesn't always travel fast.

Get a checkup. Life is worth it.

Liver Transplantation for Malignant Disease

Results in 93 Consecutive Patients

JOHN G. O'GRADY,* REX J. POLSON,* KEITH ROLLES,† ROY Y. CALNE,† and ROGER WILLIAMS*

Ninety-three patients with malignant disease underwent orthotopic liver transplantation between May 1968 and April 1987 in the Cambridge/King's College Hospital program. Of 50 patients with primary hepatocellular carcinoma (HCC) (19 with cirrhosis, 31 without cirrhosis, including 7 with fibrolamellar variant), 37 (74%) survived for more than 3 months, and in this group evidence of tumor recurrence was obtained in 24 (64.9%), the longest survivor being 11.8 years post-transplant, and three survived for more than 5 years. Although there is no correlation between the frequency of tumor recurrence and underlying cirrhosis, or histologic type (except fibrolamellar variant), it was observed earlier in those with moderate/poorly differentiated tumors and also when prednisolone and azathioprine was used for immunosuppression. Tumor recurred in all but two of those with peripheral or central cholangiocarcinoma (one alive at 6.1 years) with median survival times of 34 weeks and 56 weeks for the central and peripheral types, respectively. Among the unusual primary tumors, one with epithelioid haemangioendothelioma developed tumor recurrence at 2 years, one of two patients with apudoma is tumor-free at 2.2 years, and the one patient with bile-duct papillary cystadenocarcinoma is alive at 1.7 years. For the secondary hepatic malignancy group, survival times were shorter with little palliation except for two patients with carcinoid syndrome who were free of associated symptoms at 6 and 10 months. Despite the overall high frequency of tumor recurrence in most categories of hepatic malignancy, liver transplantation gave worthwhile survival with a number of patients cured and in the others considerable palliation of symptoms.

From the Liver Unit, King's College Hospital, School of Medicine and Dentistry, London, England, and the Department of Surgery, Addenbrooke's Hospital, Cambridge, England†*

IN THE EARLY DAYS of clinical liver transplantation, primary malignant disease was a favored indication with less difficult surgery and fewer postoperative complications than when transplantation was carried out for advanced cirrhosis. Up until 1979, over 50% of the transplants performed in the Cambridge/King's College Hospital program were for malignant conditions, although it soon became clear that tumor recurrence was all too frequent. Indeed Starzl has written that this form of treatment is conceptually unsound, this view being based on his results in 54 patients with malignant disease transplanted between 1963 and 1985.[1,2] The only patients in that series without frequent early recurrence were those with small hepatomas found incidentally at transplantation carried out for chronic liver disease and the subgroup of patients with the fibrolamellar variant of hepatocellular carcinoma (HCC).[1,2] Although this view has gained some acceptance, other centers including our own and that of Pichlmayr's at Hannover, have continued to transplant patients with malignant disease on the basis that at least in some instances cure is obtained and in others worthwhile palliation.

For the present report we have analyzed the results obtained in a series of 93 consecutive patients with either primary or secondary malignant liver disease treated by transplantation between May 1968, the beginning of the Cambridge/King's College Hospital program, and April 1987.

Materials and Methods

The 93 patients comprised 50 with primary HCC, 26 with either peripheral or central cholangiocarcinoma, nine with unusual primary tumors (five with angiosarcoma or sarcoma, one with epithelioid haemangioendothelioma, two with apudoma, and one with bile-duct papillary cystadenocarcinoma), and 8 with secondary hepatic malignancy including two with the carcinoid syndrome. Of the 50 patients with HCC, 19 had an underlying cirrhosis. The 31 cases arising in a noncirrhotic liver included seven with the fibrolamellar variant (Table 1). There were five patients in the cirrhotic group and three noncirrhotic cases with evidence of hepatitis B virus infection; these included one patient without cirrhosis in whom the only marker was HBV-DNA integration in tumor cells. Four of the patients in the non-

TABLE 1. *Data Relating to Groups of Patients Treated with Primary Hepatic Malignancy*

Malignancy	N	Age (yr) Median	Age (yr) Range	Sex Distribution (M:F)	Interval Between Onset of Symptoms and Transplant
Hepatocellular carcinoma					
Cirrhotic	19	50	5–59	15:4	6 mo (3 wk–6 mo)
Noncirrhotic	24	42	10–61	10:14	6 mo (3 wk–9 mo)
Fibrolamellar	7	23	14–51	1:6	5 mo (3–12 mo)
Central cholangiocarcinoma	13	46	16–53	7:6	8 mo (2–24 mo)
Peripheral cholangiocarcinoma	13	49	28–64	7:6	6 mo (4 wk–18 mo)
Bile-duct papillary cystadenocarcinoma	1	36		1:0	2 mo
Primary sarcoma/angiosarcoma	5	32	4–49	2:3	6 mo (3–10 mo)
Epithelioid hemangioendothelioma	1	30		0:1	8 mo
Apudoma	2	34, 36		1:1	2, 4 yr

cirrhotic group had a history of long continued oral contraceptive pill usage.

Six of the cirrhotic patients with HCC had solitary tumors ranging from 2.7 to 6 cm, and 13 had multifocal tumors between 5 and 10 cm in diameter. Tumor masses were generally larger in the noncirrhotic group, and 19 of the 31 cases had a single large lesion of 8–21 cm in diameter, with associated smaller satellite lesions in seven instances. In 12 cases there were multiple masses of between 8 and 15 cm in diameter. Tumor masses in peripheral cholangiocarcinomas were of similar size (8–19 cm in diameter with several discrete masses in six cases); the central cholangiocarcinoma tumors (presenting as biliary obstruction) comprised mainly small scirrhous lesions. Seven of these had been previously treated by surgical insertion of a stent. Two of the cases had a long history of sclerosing cholangitis.

The two patients with apparently primary hepatic apudomas were first diagnosed 2 and 4 years previously and had large tumor masses with increased circulating levels of glucagon/somatostatin and calcitonin/gastrin/pancreatic polypeptide, respectively. The secondary hepatic deposits group included two patients with the carcinoid syndrome and large multiple masses throughout the liver whose symptoms (diarrhea, flushing) were disabling and no longer responded to pharmacologic therapy and repeated hepatic artery embolization. Four patients had earlier resections of a primary tumor elsewhere and in the remaining two cases the extrahepatic primary was removed at the time of transplantation (Table 2).

TABLE 2. *Data Relating to the 8 Patients with Secondary Hepatic Malignancy Treated by Transplantation*

Primary Tumor	Age (yr)	Sex	Resection of Primary
Meningiosarcoma	31	F	4 years previously
Colon	31	F	3 mo previously
Pancreas (tail)	45	F	3 mo previously
Nephroma	54	M	At transplantation
Leiomyosarcoma	57	M	At transplantation
Colon	45	M	11 mo previously
Carcinoid of small bowel	48	M	2 yr previously
Carcinoid of lung	51	F	4 yr previously

In screening for extrahepatic spread, ultrasonographic examination of the upper abdomen, CT scan of thorax and abdomen (replacing whole lung tomography and abdominal lymphangiography used in the earlier patients), and radioisotope bone scanning were carried out routinely. Radiologically demonstrable tumor invasion of a resectable portion of the portal vein was not considered an absolute contraindication to transplantation. In addition, six patients had an exploratory *mini-laparotomy* as part of the transplant workup.

The transplant operation was carried out as described elsewhere.[3] Biliary reconstruction was obtained using predominantly choledochocholedochostomy up to 1975 and thereafter with the biliary conduit technique, except in patients with primary sclerosing cholangitis who had a Roux-en-Y anastomosis.

Sixty-six of the 93 patients had had a previous surgical procedure related to the malignancy (Table 3) including the six patients who had a mini-laparotomy as part of transplantation workup already referred to. In five of these patients a hepatic resection was attempted but not found to be feasible. One of the six patients with previous successful local resection underwent enucleation of a 4-cm HCC from a cirrhotic liver in Japan 2 years prior to transplantation, and there were four cases in the noncirrhotic HCC group who had resections 8 months, 2 years, 3.5 years, and 5.5 years previously, while the final patient had five previous resections spanning a 10-year period.

Statistics

Statistical methods employed include Kaplan-Meier cumulative survival curves, chi square test with Yates correction, and the Mann-Whitney U test.

Results

Primary Hepatocellular Carcinoma

Three-month survival figures were 68.5% for those with an underlying cirrhosis and 77.4% for the noncir-

TABLE 3. *Surgical Procedures Prior to Liver Transplantation*

rhotic group (Fig. 1). Deaths during this early period were due to operative and postoperative hemorrhage (42%), graft failure (25%), sepsis (25%), and chronic rejection (8%). Patients in the noncirrhotic group who had undergone a previous resection or exploratory laparotomy (including mini-laparotomy) had a higher mortality rate (5/20 *vs.* 0/11, $p < 0.05$). There was a similar trend in the cirrhotic patients, but it did not reach statistical significance (3/6 *vs.* 3/13, $p > 0.05$).

After 3 months, the survival curves for the cirrhotic and noncirrhotic groups were also similar with 1- and 2-year survival rates, respectively, of 42.5% and 37.3% as compared to 48.5% and 38.3% (Fig. 1). Tumor recurrence accounted for 59% of the deaths after 3 months, while the remainder were due to sepsis (22.7%) and chronic rejection (9.1%) with single instances of mitozanthrone cardiotoxicity and carotid artery erosion complicating prolonged endotracheal intubation for chronic respiratory failure. Twelve of these patients survived for more than 1 year including two who were free of tumor at the time of death over 5 years post-transplantation. Of the ten patients in this series who are currently alive (as of October 1, 1987), there are five who are more than 1 year post-transplantation, with two of these alive at 4.8 and 11.8 years and free of detectable tumor.

Tumor Recurrence

Tumor recurrence was diagnosed in 24 (64.9%) of 37 patients who survived at least 3 months post-transplantation with no difference between the cirrhotic (69.2%) and noncirrhotic groups (60.0%). Eleven patients were asymptomatic with respect to tumor recurrence at the time this was detected and remained so for a further median period of 6 months (range: 2–13 months). Evidence of recurrence was based on an increase in serum alpha-fetoprotein level (0.7–1.7 years post-transplantation) or appearance of metastases on chest X-ray, ultrasonographic examination, or CT scan (at 3 weeks to 3.3 years) (Fig. 2). The most common clinical signs comprised return of original symptoms (abdominal discomfort, nausea and vomiting, weight loss), pyrexia, skin/buccal mucosa nodules, and pain from skeletal deposits. The principal sites of documented tumor recurrence in the 23 patients were liver (57.9%), lung (57.9%), adrenal (42.1%), bone (26.3%), abdominal cavity (21.1%), and skin (15.8%). In two of four patients with skin metas-

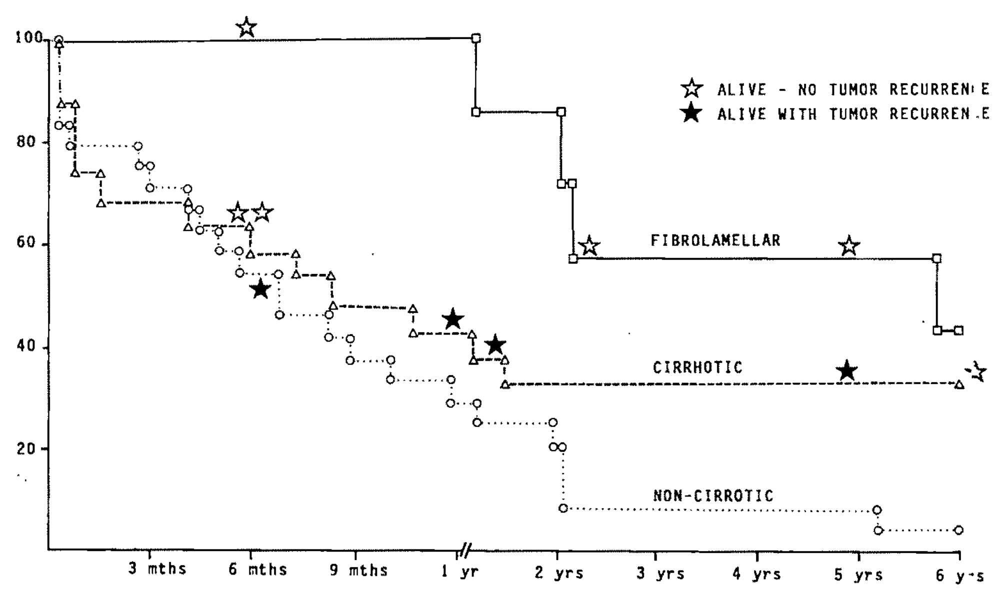

FIG. 1. Kaplan-Meier survival curves for patients transplanted with fibrolamellar HCC and nonfibrolamellar HCC arising in cirrhotic and noncirrhotic livers.

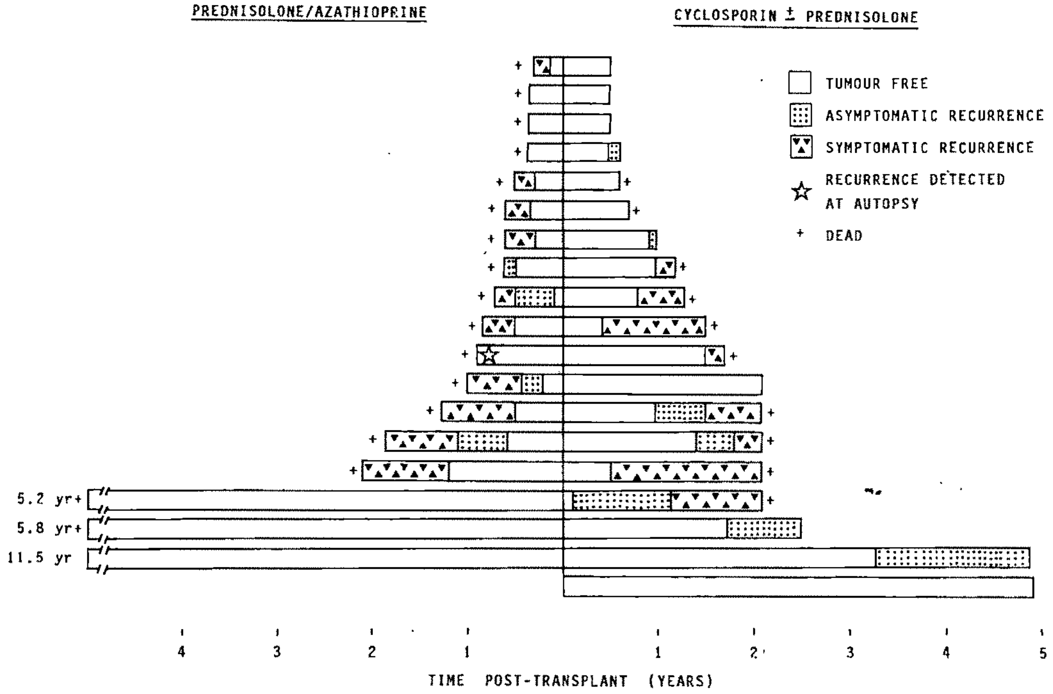

FIG. 2. Overall survival in patients transplanted for HCC and immunosuppressed with prednisolone/azathioprine (1967–1979) or cyclosporine and prednisolone (1980–1987) with breakdown for oncologic-free periods and duration of asymptomatic and symptomatic tumor recurrence.

tases, isolated lesions developed at the site of puncture for a liver biopsy or percutaneous cholangiogram performed prior to transplantation. Ten of the patients who developed recurrence were totally free of symptoms for more than 1 year including one remarkable patient who remains well at 4.8 years with tumor regression on chemotherapy using mitozanthrone and 5-fluorouracil.

Among the seven patients with the fibrolamellar variant of HCC, tumor recurrence was detected in three patients at 6, 9, and 18 months, leading to death at 1.1–2.2 years. Three patients are alive and free of detectable tumor at 3-months, 1.8 years, and 4.5 years, respectively, while the remaining patient was free of tumor when she died 5.8 years post-transplant from sepsis and variceal bleeding complicating the development of cirrhosis (from a transfusion acquired non-A, non-B hepatitis).

The median interval between transplantation and death from recurrence was longer in patients with a well-differentiated tumor on histologic examination than in those with a moderate/poorly differentiated tumor (2 years and 33 weeks, respectively; $p < 0.05$) and all three patients free of detectable malignancy at 2 years had well-differentiated tumors. No correlation was found between tumor size and frequency or rapidity of recurrence, although it is noteworthy that one patient with a 21-cm tumor with multiple smaller lesions was free of tumor at 5.2 years post-transplantation. No correlation was found between tumor recurrence and previous surgery in the noncirrhotic patients surviving more than 3 months (54.5% and 60.0%, respectively), although in the cirrhotic group all three patients who had a previous laparotomy (two exploratory, one minilaparotomy) developed recurrence as compared to four of ten patients who had not had previous surgery.

Comparison of tumor recurrence rates for the two main immunosuppression regimens used in the program showed no difference between 18 patients maintained on prednisolone/azathioprine and 19 on cyclosporin ± prednisolone (66.7% and 63.2%, respectively), although median survival was longer in the cyclosporin-treated group (9 months and 15 months, respectively; $p < 0.05$). The interval between the time of transplantation and detection of tumor recurrence was also greater in patients on cyclosporin (median: 12 months; range: 3 weeks to 3.3 years) than in the prednisolone/azathioprine group (median: 6 months; range: 4 weeks to 1.2 years; $p < 0.05$). Since nine of the patients on cyclosporin (47.4%) are currently alive as compared to only one in the prednisolone/azathioprine group, it is likely that this difference will become even further accentuated.

Changes in Alpha-fetoprotein

Serial levels for six of the earlier patients have previously been published,[4] indicating a return to within the normal range (<10 ng/mL) in four cases with a half-life of 3–8.5 days. One of these patients continues to have a normal level at 11.8 years, but in the other three patients within 4 months of transplantation the levels had increased again to above the normal range. Since then there have been a further six cases in whom serum alpha-fetoprotein levels have returned to normal following the transplant. Two of these remain negative at 4–8 months (Fig. 3), and in two patients the level remained in the normal range for at least 10 months before rising again in association with recurrent disease. The sixth patient had only a modest rise in alpha-fetoprotein (31 ng/mL) at 1 year when tumor recurrence was diagnosed.

Cholangiocarcinoma and Other Primary Tumors

Survival curves for both the central and peripheral cholangiocarcinomas are similar (Fig. 4) with 3-month survival rates for both of 53.8%. Sepsis was the major cause of death during this period (81.8%), with hemorrhage (9.1%) and acute graft failure (9.1%) much less frequent. One-year survival rates were also similar for the central and peripheral tumors (30.7% and 38.4%, respectively).

Of the seven patients with central cholangiocarcinoma who survived 3 months, six have documented recurrence of tumor (abdomen five, lung four, bone two, liver one, and skin at operative drain site one) leading to death, a median of 34 weeks post-transplantation. One patient without tumor recurrence who had presented with obstructive jaundice due to a 13-cm cholangiocarcinoma at the hilum is alive and well at 6.5 years. One of the seven patients with peripheral cholangiocarcinoma died at 4 months as a consequence of an intracerebral vascular accident. The other six developed recurrence of tumor (abdomen five, lungs three, liver two, bone two, and cervical lymph nodes one), but the median survival for this subgroup was longer at 1.1 years (range: up to 3.2 years) compared with the central cholangiocarcinoma patients.

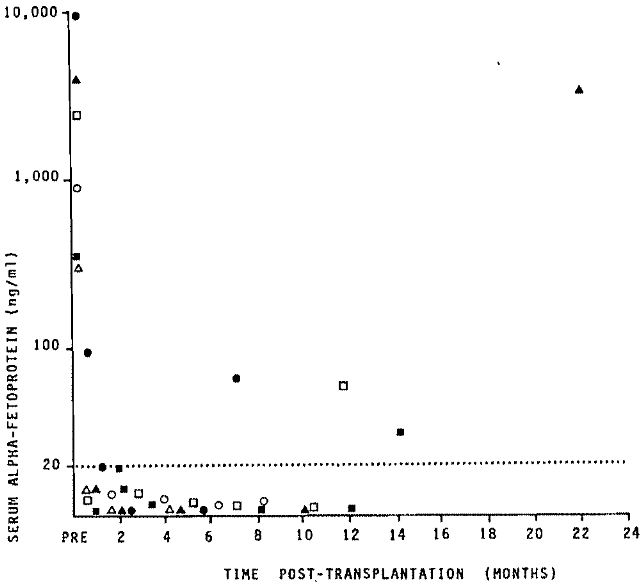

FIG. 3. Serial alpha-fetoprotein levels in six patients with elevated levels pretransplant, which returned to the normal range after surgery.

Four of five patients with primary sarcoma/angiosarcoma died within 7 weeks of surgery as a consequence of hemorrhage or sepsis and the remaining patient has tumor recurrence at 6 months. The single case of epithelioid hemangioendothelioma was in good health for 22 months but then developed rapidly progressive hepatomegaly in association with an apparent microangiopathic hemolytic anemia and impaired renal function, leading to death 2 months later. At autopsy the liver graft was extensively replaced by tumor with no evidence of malignancy elsewhere. The single patient with bile-duct papillary cystadenocarcinoma is alive and free of detectable tumor 20 months after transplantation as

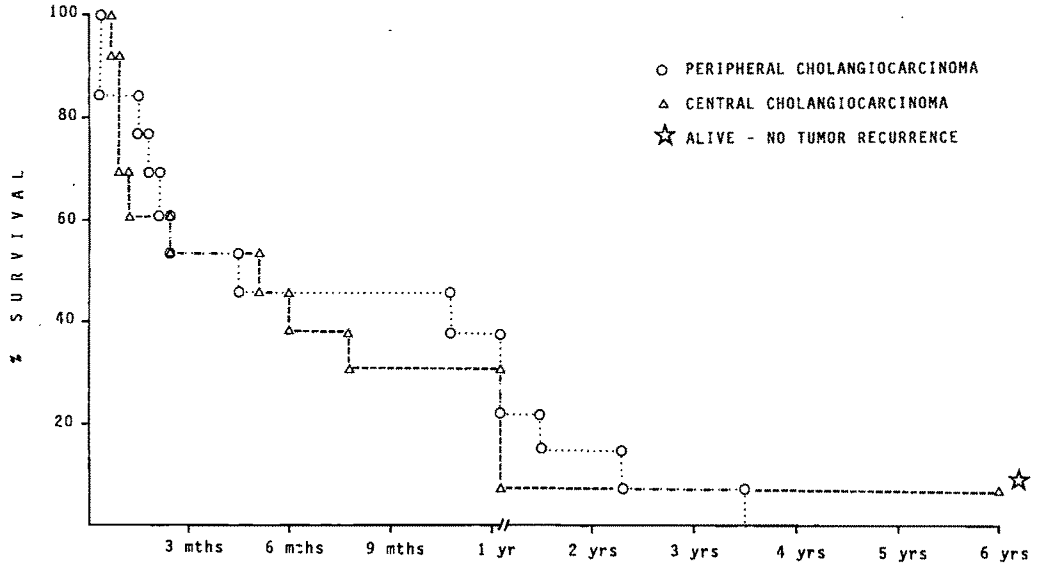

FIG. 4. Kaplan-Meier survival curves for patients transplanted with peripheral and central cholangiocarcinoma.

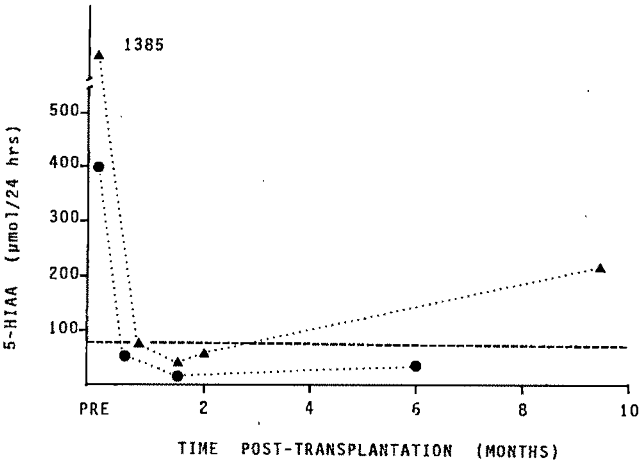

FIG. 5. Urinary excretion of 5-HIAA preliver and postliver transplantation for the carcinoid syndrome.

is one of the two patients with apudomas (2.2 years after transplantation). The other patient with an apudoma had no evidence of recurrence at the time of death from chronic graft rejection (7 months).

Secondary Hepatic Malignancy

Only three of the six patients transplanted for hepatic metastases survived for 3 months, and these died between 22 and 41 weeks from recurrent disease. Of the two patients with the carcinoid syndrome, one died at 7 months with chronic rejection with a normal 5-HIAA excretion; the other is symptom-free at 12 months with no radiologic evidence of tumor recurrence but with increasing levels of 5-HIAA excretion, initially detected at 9.5 months (Fig. 5).

Discussion

The high recurrence rates of primary HCC following transplantation, even in the most recent cases, can only be considered disappointing. Although there have been a number of advances in radiologic techniques for the detection of extrahepatic spread prior to surgery, these are still subject to considerable limitations. Thus, in one recent study of CT scanning, 20–47% of various patient groups had macroscopic tumor nodules at the time of surgery that were not apparent on scanning.[5] It seems reasonable to assume that recurrence of tumor following transplantation is based on microdeposits already present in extrahepatic sites or released during surgical manipulation. Of particular interest was the finding that in cases with a raised alpha-fetoprotein level in serum postoperatively, this could fall to and remain within a normal range for periods of up to 10 months before rising again in association with other evidence of tumor recurrence. Whether adjuvant chemotherapy after transplantation could prolong this interval further or prevent recurrence from developing remains to be established.

The most favorable results reported are those with small asymptomatic tumors found incidentally at the time of transplantation, with 12 of 13 such patients in the Starzl et al. series remaining free of tumor recurrence between 4 months and 15 years (median: 16 months).[1] Most of the cases in the present series that were detected by screening of cirrhotic patients by ultrasonographic examination and alpha-fetoprotein levels had larger tumors than this (>2.7 cm), indicating the need for even more intensive screening of high-risk groups. The recurrence rate in our series with the larger primary HCC tumors was lower at 64.9% than the 77.8% in Starzl's series.[1] In addition, long-term cures were obtained in patients who had not been suitable for hepatic resection because of the localization or extent of tumor or the presence of cirrhosis, and in the remainder considerable palliation was often achieved particularly with well-differentiated tumors and when cyclosporin was used as the main immunosuppressive agent. In several cases subsequent chemotherapy, and in two instances surgical removal of isolated secondary deposits in the adrenal gland, appeared to prolong the period of worthwhile palliation and survival.

The present experience would, however, be in accord with the data of Starzl et al. with respect to the fibrolamellar variant of HCC as the best subgroup, in which 1-year survival was 100% in both series of seven cases each and with overall recurrence rate of 50%.[2] Good results are also obtained with this tumor when local resection is feasible as demonstrated by the study of Soreide et al. of seven patients who survived for between 8 and 41 months with one instance of tumor recurrence during this period.[6]

Whether tumor growth is accelerated by immunosuppression following transplant is difficult to determine. In the present study it is of interest that the rate of growth appears to be slower in patients maintained on cyclosporin, as suggested by the longer median tumor-free interval (12 months) post-transplantation and the longer lag period before the reappearance of alpha-fetoprotein in serum. In the study by Iwatsuki et al.[1] the median interval between transplantation and HCC was only 4 months, but many of these patients were probably treated in the precyclosporin era. The possible acceleration of tumor growth by immunosuppressive therapy was one of the factors prompting the conclusion of Iwatsuki et al. that transplantation for malignant disease was conceptually unsound.[1] We believe this conclusion needs to be reconsidered with greater dependence on cyclosporin, especially since a median oncologically free interval of 1 year provides a good basis for worthwhile palliation.

The chances of a potentially curative resection of central (bile-duct) cholangiocarcinoma being possible are small, as indicated in the study by Blumgart et al. in which only 18 of 94 patients with hilar cholangiocarcinoma were treated in this way, and these had a mean survival of 17 months.[7] A greater percentage of such patients are amenable to treatment by transplantation, and our 3-month survival rate of 53.8% is similar to the 50% achieved by Iwatsuki et al.[1] However, only two patients in both studies have remained free of tumor. No patient with peripheral cholangiocarcinoma has to date been cured of tumor, although a median survival of 1.1 years with a range of up to 3.5 years represents worthwhile palliation. Poor results with primary angiosarcoma/sarcoma are not surprising, but the recently recognized variant, epithelioid hemangioendothelioma, with a much less aggressive natural history remains a worthwhile category.

Patients with apudomas and secondary carcinoid tumors constitute a special group with respect to liver transplantation. Not only is tumor growth naturally slow with these tumors, but the dramatic relief of associated symptoms obtained with a successful graft, particularly the disabling carcinoid syndrome, is a remarkable event to witness.

Our results do little to support the use of transplantation for patients with secondary hepatic malignancy (excluding carcinoid). Pichlmayr et al., however, considered the palliation conferred by transplantation to be valuable despite the short period of survival.[8] The most encouraging data comes from the Vienna group who reported a 70% 1-year survival in ten patients, with one patient free of detectable tumor at 3 years.[9] There is also a single patient in the UCLA series with metastatic gastric leiomyosarcoma who is alive and free of detectable tumor 21 months post-transplantation.[10] At least some categories of patients within this group probably merit reconsideration with regard to transplantation, especially those with hepatic metastases for a primary colonic carcinoma resected some years previously.

Surgical Procedures among Those $\geq$90 Years of Age

A Population-based Study in Olmsted County, Minnesota, 1975–1985

MARK A. WARNER, M.D.,* MICHAEL P. HOSKING, M.D.,* CREIG M. LOBDELL, PH.D.,† KENNETH P. OFFORD, M.S.,‡
and L. JOSEPH MELTON III, M.D.‡

Persons $\geq$ 90 years of age represent a rapidly growing subset of the population, but little data exist on their utilization of the health care system. Population-based data capabilities of the Rochester/Olmsted County Epidemiology Project were used to study the performance of surgery among persons $\geq$ 90 years of age for the 11-year period, 1975–1985. During this time, 224 residents of Olmsted County, Minnesota underwent 301 separate operations. The annual operation rate increased over the course of the study (trend test, $p < 0.001$), reaching a plateau of 89.0 per 1000 person-years. This suggests a potential for nearly 91,000 operations annually in this age group based on 1987 U.S. Census estimates. Ninety-two per cent were discharged from the hospital alive, and 5-year survival was consistent with that expected (23% *vs.* 17%). Increased longevity of the general population, combined with increased performance of surgery in this rapidly growing segment of the population, may have significant implications for health care planning.

From the Department of Anesthesiology, Mayo Medical School,† and the Department of Medical Statistics and Epidemiology,‡ Mayo Clinic and Mayo Foundation, Rochester, Minnesota*

THERE is little information on the utilization of the health care system by people $\geq$ 90 years of age. The federal government, for example, considers all persons $\geq$ 65 years of age a single cohort for data collection and future projections. Attempting to fill this information gap, Torrey[1] found that people > 80 years of age received 77% more Medicare dollars than people 65 to 69 years of age, amounting to about \$50 billion per year. This has somewhat ominous implications economically because the very old represent a rapidly growing segment of the U.S. population. People $\geq$ 90 years of age will number an estimated 1,901,000 by the year 2000.[2] This represents a compound annual growth rate of 4.4%, or a 236% increase between 1980 and the end of the century.[2,3] A further dramatic rise will occur as the baby boom cohort reaches advanced age.

In addition to these dramatic demographic changes, it was our impression that more elderly individuals were undergoing surgical procedures over the past decade. If true, future costs of medical care for this segment of the population may be even greater than currently projected, and additional surgical resources will be required. Consequently, we studied the performance of surgery among residents of Olmsted County, Minnesota, who were $\geq$90 years of age during the 11-year period, 1975–1985.

Methods

It was possible to undertake this study in Olmsted County, Minnesota because the diagnoses made and the surgical procedures performed on County residents by virtually all medical care providers are indexed, and the original medical records can readily be retrieved for review. The value of this data system, the Rochester/Olmsted County Epidemiology Project, for population-based studies has been described previously.[4,5]

During the 11-year period, 1975–1985, 301 operations involving 319 procedures were performed at the Mayo Clinic on 224 Olmsted County residents $\geq$ 90 years at the time of surgery. None of the other county physicians operated on any Olmsted County resident in this age group. Only permanent residents of Olmsted County were included.

Each patient was classified preoperatively according to the physical status classification (ASA class) of the American Society of Anesthesiologists,[6] and preoperative medical conditions were determined by individual chart review. At our institution, patients are required to undergo a preanesthetic medical examination by an internist prior to a surgical procedure, and, in addition, all patients complete a questionnaire detailing their medical history. Moreover, because Mayo utilizes a unit record system, the complete history containing outpatient as well as inpatient data is available for review. Hypertension, angina, chronic obstructive pulmonary disease, endocrine disease, and arrhythmia were defined as present if the patient was receiving medical therapy for the condition at the time of operation. Previous myocardial infarction was identified by the presence of Q-waves on electrocardiogram. Prior coronary artery bypass or cardiac valvular surgery were recorded. Smoking history was obtained from the patient questionnaire. A preoperative creatinine level > 2.0 mg/dL or the use of dialysis indicated renal dysfunction. Prior malignancy as well as surgery, chemotherapy, or radiation therapy for malignancy were recorded. Central nervous system disease was identified in patients with medically documented cerebral vascular accident, transient ischemic attack, or neurologic deficit of central origin. Biliary disease was present if the total bilirubin was >3.0 mg/dL, alkaline phosphatase > 375 U/L, or AST > 45 U/L.

Per capita utilization rates were calculated as incidence rates (incidence density) per 1000 person–years (p–y), assuming the entire population in this age group

to be at risk. Since Olmsted County data are available only for the age group ≥ 85 years, the Olmsted County population ≥ 90 years of age at the 1980 census was estimated using the 1980 census population for age ≥ 85 years for Olmsted County multiplied by the proportion of these who were ≥90 years old in 1980 census data for Minnesota. For individual calendar years 1975–1979, the 1980 numbers were decreased by the compound annual growth rate for each sex based on the U.S. white population age ≥ 90 years in the 1970 and 1980 census reports.[3,7] For years 1981–1985, the 1980 numbers were increased according to U.S. white population projections.[2,8] Summing these over the 11-year period produced a denominator for the surgery utilization rates of 3,739 p-y (799 p-y in men, 2940 p-y in women). Survival curves were estimated using Kaplan-Meier methodology.[9] Expected survival curves for deaths from all causes were computed for persons of like age, sex, and calendar year of birth, based on cohort life tables constructed for the West North Central region of the United States.[10]

Results

In the 11-year period, 1975–1985, 224 Olmsted County, Minnesota, residents who at the time of surgery were ≥90 years of age underwent 301 separate operations at which 319 specific surgical procedures were performed. Among residents having surgery, most (163, 73%) had only one operation during this interval, but 48 (21%) had two and 13 (6%) had three or more. Of the total operations in this group, two-thirds were in women, but the incidence of operations was over 80% greater in men. A similar excess among males was seen whether surgical utilization was based on individual patients, on total operations, or on all surgical procedures (Table 1).

The overall annual operation rate among Olmsted County residents ≥ 90 years of age was 80.5 per 1000 (95% confidence interval: 71.7–90.1). However, the number of operations rose from five per year in 1975 to 40 per year in 1985. Even with these limited numbers of cases, an increase in the operation rate was apparent over the course of the study (trend test, $p < 0.001$), with the appearance of a plateau for the final 8 years (Fig. 1). This suggests for 1987 a potential for 90,958 operations annually in this age group if the average annual rate over the last 8 years of 89.0 per 1000 were applied to the total U.S. estimated population for 1987 of 1,022,000 individuals ≥ 90 years of age.

Of the total 301 operations, 23% were in individuals

95 years of age and older, while 2.3% were 100 years of age or more. Not surprisingly, a substantial proportion of these elderly individuals had one or more chronic diseases or conditions (Table 2). These data are reliable despite any cognitive difficulties in the patients because their documented length of medical care at Mayo prior to surgery averaged 44.3 years (median: 50 years), and this complete record was available for review. The prevalence of preoperative disease is reflected in the ASA status of this group, with 85% ASA Class 3 (severe systemic disturbance or disease) or worse.

The indications for surgery, as classified by the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM), were distributed into 14 major categories (Table 3). Diseases of the digestive system and fractures of the femur were most common (22.0% each), followed by diseases of the nervous system and sense organs (12.2%). The ICD-9-CM system is a clinical index that allows differentiation among diseases specific to a system and disease processes that may occur in that system. For example, the classification of diseases of the digestive system includes diseases specific to it, such as hernias or peptic ulcers, but does not include neoplasms that may occur in it (or elsewhere). These neoplasms are classified separately.

Nearly half (47%) of the operations involved general

TABLE 5. *Causes of Death*

Time of Death	No. of Patients	No. Dying and Cause of Death*

Within 48 hours of operation (not including intraoperative period)	4	1, infarcted bowel 1, pulmonary embolis following hip pinning 1, carcinomatosis 1, pneumonia and sepsis
Within 30 days of operation (not including within 48 hours of operation)	17	4, infarcted bowel 4, carcinomatosis 3, cerebrovascular stroke following lymph node biopsy (1) and total hip arthroplasty (2) 2, myocardial infarction following hip pinning 1, ruptured abdominal aortic aneurysm 1, gangrenous gallbladder 1, pulmonary embolis following hemicolectomy 1, pulmonary hemorrhage from bronchiectasis

* Major underlying disease process or cause of death is identified.

anesthesia. The primary anesthetic technique in the remainder included regional in 17%, intravenous (I.V.) sedation with or without local anesthesia in 15%, and local anesthesia in 21%. This distribution of anesthetic techniques was dictated largely by the surgical procedures performed (Table 4). Sixty-three per cent of the procedures involved the gastrointestinal (GI) (including hernias), genital, or musculoskeletal systems. Operations for fractures accounted for 25% of all surgical procedures. This finding is related to the observation that 26% of all operations were for trauma and that 19% were emergency operations.

Despite the significant nature of many of the surgeries and the prevalence of chronic disease, these elderly Olmsted County residents faired quite well. Ninety-two per cent were discharged from the hospital alive following surgery. Of the 28 deaths within 30 days, seven occurred intraoperatively and four others within 48 hours of operation (Table 5). While survival was slightly impaired immediately following surgery when compared with expected values for the general population of like age and sex (Fig. 2), the estimated survival at the end of 1 year was 74%, the same as expected. For years 2 through 5, the cumulative observed survival was slightly better than expected so that by 5 years after the initial surgery, the observed survival was estimated at 23% compared to an expected 17%.

Discussion

We have observed that the rate of surgical procedures on patients ≥ 90 years of age increased nearly fivefold between 1975 and 1978, and then seemed to level off somewhat. The cause of this increase and plateau is unclear. The abrupt increase may have coincided with the widespread use of a new surgical procedure, such as total hip arthroplasty or lens implant, that would have been commonly used in this age group. We were not, however, able to identify such procedures in our patient population (Table 6). Another change in medical practice during this period was the more liberal use of perioperative invasive monitoring. This change may have influenced surgeons to operate on sicker (and frequently older) patients. We are not able to address this hypothesis with our data.

Using 1987 U.S. Census projections, there exists a potential for nearly 91,000 operations in this age group each year if the annual rate of 89.0 per 1000 for the final 8 years of the study is applied to the entire U.S. population of this age. As surgical indications for these extremely elderly individuals are liberalized throughout the country, care will be even more expensive for this rapidly growing segment of the population.

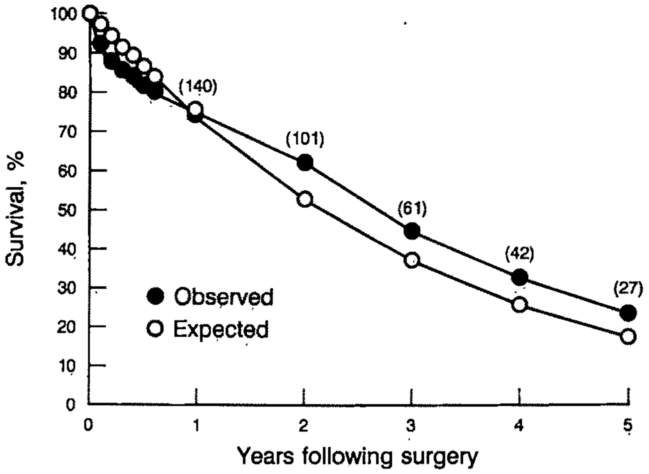

FIG. 2. Survival of 224 Olmsted County, Minnesota residents ≥ 90 years of age following surgery (1975–1985). For patients with multiple surgeries ≥ 90 years of age, only the first surgery was used, and time 0 is the date of first surgery. The number of persons alive and being followed at yearly intervals is given in parentheses.

Using a geographically defined community population for study, we avoided the distortions of referral bias.[11,12] Referral patients do provide the bulk of our surgical workload, however, so that no inherent temptation exists to increase operative rates in the local population. Moreover, all physicians in our practice are salaried with no financial incentives or disincentives for deciding to use a procedure. Although these considerations do not insure optimal practice, nonmedical considerations in the surgical decision process are minimized.[13]

Estimates based on the Olmsted County population do have several potential disadvantages, however. There are very few nonwhite residents; if surgical utilization rates differ for white and nonwhite people ≥ 90 years of age, Olmsted County estimates cannot be applied to the nonwhite population nationally. The Olmsted County rates might also provide an underestimate if there is greater per capita performance of surgery in major metropolitan areas. Although the proportion of urban residents in Olmsted County (71%) is the same as that nationally, Rochester is a small city and surgical rates may not be entirely applicable to larger cities.[14] Finally, our projection underestimates the incidence of operations if indications for surgery in this age group are liberalized further.

Liberalization of indications is influenced, in turn, by the outcome of surgery. One might have expected poor survival in these individuals because chronic diseases were so common[15]; 85% were ASA Class 3 or greater. This scale has been demonstrated to be applied with remarkable consistency by different groups of anesthesiologists.[16] Although not intended as a predictor of perioperative risk, several studies have demonstrated it to be a reliable predictor of overall outcome.[17,18] Despite the prevalence of chronic illness in this group, however, 92% were discharged from the hospital alive following surgery. When compared with peers from the general population, the modest increase in mortality rates in the first 6 months had reversed after 1 year, and, at 5 years, survival in the surgery group was somewhat higher than that expected.

The 9.3% 30-day postoperative mortality rate of our patients represents a marked improvement from reported mortality rates in this age group in the past two decades. Denney and Denson,[19] in 1972, reported on 272 patients ≥ 90 years undergoing procedures similar to our patients and in approximately equal ratios. They found a 30-day postoperative mortality rate of 29%. Interestingly, the major causes of death in their series were pneumonia and atherosclerosis with myocardial infarction. We did not find either to be a major cause of death (Table 5). This enhanced early survival may be due to surgical and anesthetic advances and improved medical care. We were not, however, able to demonstrate an improvement in mortality rate over the 10-year period of our study.

* Crude annual incidence per 1000.

In summary, we have seen both an absolute and relative increase in surgical utilization in this age group. The population 90 years of age and over is growing, the perioperative mortality rate is not markedly different from the mortality rate in the general peer group, and survival may be enhanced by surgical intervention. Increasing rates of surgery in this group, combined with improved survival of operated patients, may have a significant impact on health care costs. Although a formal cost analysis is beyond the scope of this study, these findings may provide information useful in evaluating future needs for health care resources.

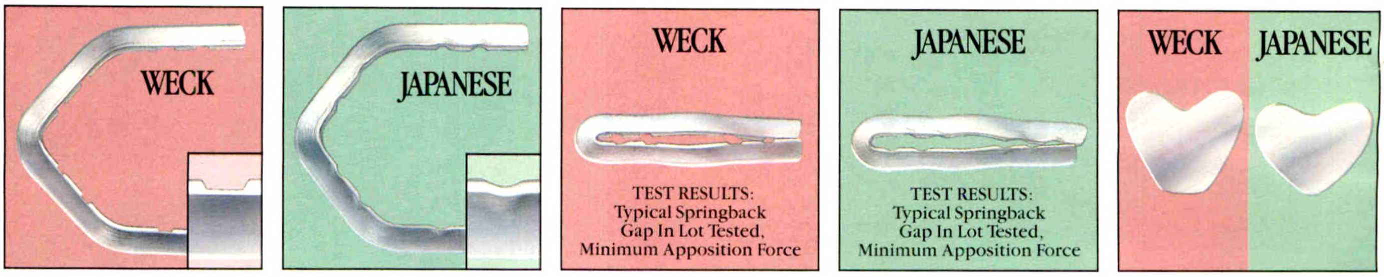
We make the Hemoclip® clip like it is because of the way nature made blood vessels.

Hemoclip® ligating clips are made for blood vessels.

That sounds obvious, but it's not to everyone.

It's not easy to make ligating clips that are finely balanced between strength and malleability–two desirable ligating clip properties.

But in a quarter-century of manufacture, Weck has learned to do the job on this key implant device as no one else has.



The Hemoclip® ligating clip is coined with distinct rectangular transverse grooves, designed for longitudinal gripping power. Clip wire is processed metallurgially for malleability in closure. The Japanese imitation clips have shallow-drawn wire, and smaller, rounded transverse grooves. Deeper Hemoclip® wire shape aids retention in Weck appliers. (Typical closure illustrated from independent study.)

But now there's a problem you should be aware of. Some U.S.-based companies have begun distributing–not manufacturing–Japanese imitations of the Hemoclip® ligating clip. These clips are not the product of Weck manufacturing expertise and the technical performance of these clips is simply not the same as that of Hemoclip® ligating clips, an exclusive Weck product.

They may look the same, but they're not.

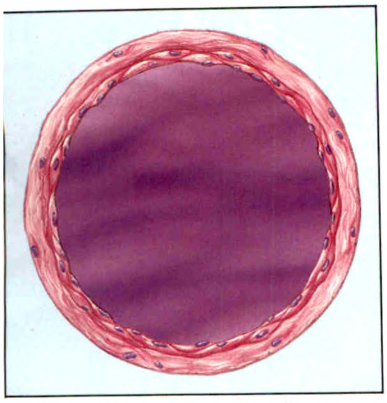
The recently-introduced Japanese clips look the same as Hemoclip® ligating clips to the naked eye. But a recently completed independent lab study of sample quantities of clips confirms Weck's own observation of substantial differences in closure properties between the Japanese clips and Weck clips.

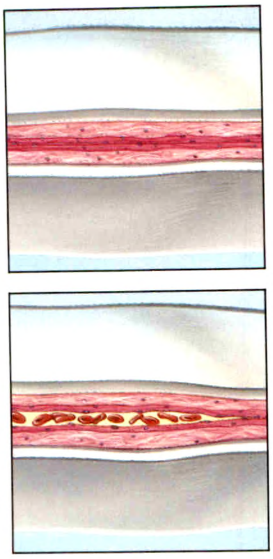
Vessel walls may be as thin as one-twelfth of vessel diameter.

Veins, in contrast to arteries, have very thin walls. When you consider that the vein tributaries ligated in surgery are sometimes one millimeter in diameter or smaller, with combined vessel walls as small as seven-thousandths of an inch (178 microns), according to animal studies on comparable vessels, you can appreciate the functional importance of differences in closure gap.

Arterial tributaries can be tiny, too, and although their walls are generally thicker than vein walls, arterial pressure is higher than venous pressure.

It seems prudent to employ ligating clips which offer the response and clip-closure performance Weck usage has established in your surgery.

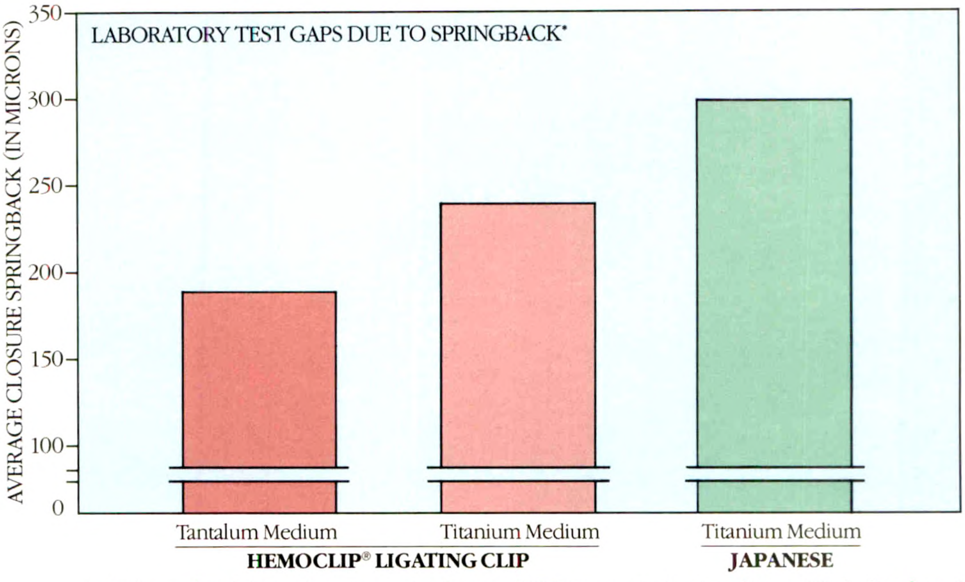




ABOVE. A vein tributary of 1mm can have a combined wall thickness of just seven-thousandths of an inch (178 microns), according to animal studies. RIGHT. A ligating clip that demonstrates greater springback than the clip you have regularly used for such vessels may be more likely to leave a closure gap larger than the vessel-wall thickness of a tiny vessel.

Weck's titanium clip vs. their titanium clip. A 23-27% difference.

Examine the chart for a visual representation of the difference in closure springback an independent research firm discovered between a set of Weck titanium medium-size clips and a set of Japanese titanium medium-size clips obtained directly from U.S. distributors of those clips. Both sets of clips were closed in Weck appliers through use of force-control devices.



An independent lab study on two sample sets of 25 Japanese imitation clips vs. Weck clips found that the Japanese medium-size clips, closed to initial complete touching of clip legs, evidenced mean closure gaps, due to springback, 23-27% larger than Weck medium-size titanium clips, and 56-61% larger than Hemoclip® tantalum clips from Weck. Other sizes produced similar results. (Closure gap in microns-one micron = one thousandth of one millimeter).

Closure of two sample sets of 25 Japanese titanium medium clips at forces adequate to achieve initial complete touching along clip legs resulted in closures of about 12 thousandths of an inch (305 microns) for the Japanese clips, 23-27% larger than the Weck titanium clip closure gap.

Weck's tantalum clips vs. their titanium clips. A 56% springback difference.

The comparison of Japanese titanium with Weck tantalum clips is even more important.

The Japanese companies make only titanium clips, and so they have sold hard on the benefits of titanium.

Tantalum is a softer material known for excellent clip closure. And the study revealed 56% and 61% larger mean closure gaps after springback for two sets of Japanese titanium clips, a ringing endorsement of the closure advantages of the Weck tantalum clips tested.

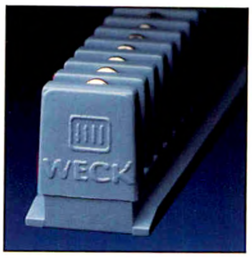
**Stronger closure forces would likely be employed during actual surgery cases.*

The comparison was similar for Weck stainless vs. Japanese titanium, with the stainless scoring substantially smaller gaps after springback.

Odds are, if you are using Weck clips you are accustomed to tantalum or stainless steel clip closure, because the vast majority of Weck accounts use these two metals.

And a new Weck-funded NMR major-university study indicates that magnetic deflection of tantalum clips is negligible, just as it is for titanium clips. So if your local competitive salesman distributing Japanese clips tries to convince you that titanium clips are exclusively acceptable for NMR magnetic deflection in preference to tantalum, we suggest you cite the new Weck-sponsored university study.

Look for the Weck name on the cartridge.



To visually and quickly confirm that you really are using Weck clips, look at the end of the clip cartridge. If you are using Weck clips, you should see there the Weck name molded into the plastic. The Weck name is your assurance of genuine Hemoclip® clip processing experience and knowledge.

Effect of T Cell Modulation on the Translocation of Bacteria from the Gut and Mesenteric Lymph Node

Although the ability of the gut-associated lymphoid tissue (GALT) to respond to orally ingested foreign antigens has been studied extensively, its function in preventing or limiting escape of resident gut bacteria has not been assessed. The following studies were performed to examine what role cell-mediated immunity (CMI) plays in this process. The ability of suppression of CMI to induce escape of gut bacteria (translocation) to the mesenteric lymph node (MLN) in immunocompetent mice whose gut flora was unaltered was examined. Administration of cyclosporine or anti-L3T4 antibody failed to induce translocation of indigenous gut bacteria after 7 or 14 days of treatment. Antithymocyte globulin (ATG) also failed to induce translocation after 7 days of treatment, despite depletion of all Thy 1, Lyt 1, L3T4, and Lyt 2 positive cells from the spleen, MLN, and intestine as demonstrated by immunofluorescent microscopy. Finally, cultures of the MLN, spleen, liver, and peritoneum of T cell-deficient BALB/c nude mice and their heterozygous T cell-replete littermates were also sterile, demonstrating that congenital suppression of T CMI also does not lead to translocation of indigenous gut bacteria. The role of CMI in limiting systemic spread of bacteria that were already translocating to the MLN was also examined. Translocation of *Escherichia coli* C25 to the MLN was induced by gastrointestinal (GI) monoassociation, which leads to translocation of *E. coli* C25 to the MLN in 80–100% of mice. Treatment with ATG during monoassociation failed to induce spread of *E. coli* C25 to the spleen, liver, or peritoneum, despite the same degree of T cell depletion achieved with ATG in the previous experiment. Monoassociation of conventional T cell-deficient BALB/c nude and heterozygous mice and germ-free T cell-deficient BALB/c nude and heterozygous mice also did not lead to spread of *E. coli* C25 beyond the MLN. However, in ATG-treated, conventional nude, and germ-free nude mice, the average number of translocating *E. coli* C25 per MLN was consistently higher. In separate experiments the ability of stimulation of T cell function to inhibit translocation of *E. coli* C25 was examined. Recombinant interleukin-2, 25,000 units, was administered intraperitoneally every 8 hours during exposure to *E. coli* C25. This reduced the incidence of translocation of *E. coli* C25 from 85% to 51% (p = 0.02). Suppression of CMI, either systemically or within the GALT, has a minimal influence on the mechanisms by which the normal gut flora are translocated to the MLN. However, suppression of CMI promotes increased survival of the bacteria that have translocated to the MLN. Conversely, augmentation of T cell function may reduce the number of bacteria that survive in the node, possibly by enhanced bacterial killing within the local environment of the MLN.

HOSPITAL-ACQUIRED or nosocomial infection continues to be one of the leading causes of death in critically ill surgical patients. Whether following trauma, burns, or routine intra-abdominal surgery, the majority of these infections are due to gram-negative bacilli, enterococci, *Candida albicans,* and coagulase-negative staphylococci. Coagulase-negative staphylococcal infections are most often due to colonization of intravascular monitoring devices. Infections caused by gram-negative bacilli, enterococci, and *C. albicans,* microbes that are normally found primarily in the gastrointestinal (GI) tract, appear at a variety of sites including the lung, peritoneal cavity, sinuses, and urinary tract. Recently, however, it has been recognized that the GI tract, due to an acquired inability to confine microbes, may also serve as a reservoir for systemic infection in these patients.[1] Because surgical patients frequently suffer from malnutrition, gram-negative infection, shock (with compromised mesenteric blood flow), ileus with its attendant stasis of intestinal contents, and lack of oral intake, the capability of the gut to maintain

its mucosal and immune barriers against the escape of microbes (referred to as translocation), may be severely compromised. Since many of these predisposing factors are often found together, systemic escape of gut microbes or toxins may have important consequences in such critically ill patients.

Although all of these factors may lead to changes in gut structure and function, it is unknown what impact depression of immune function has on the GI tract's ability to prevent escape of bacteria. In particular, many abnormalities of T cell function occur following burns, trauma, and sepsis including decreased total T cell number, diminished responsiveness to the T cell mitogen PHA and to the lymphokine interleukin-2 (IL-2), and the generation of suppressor T cells. In burn patients the degree of depression of the T cell response to PHA has been shown to correlate with both the degree of burn injury and with the risk of developing infection and of dying from infection.[2] In preoperative patients, the status of their T cell function, as measured by skin testing to ubiquitous antigens, is highly predictive of the risk of developing a life-threatening postoperative infection and of the risk of death from sepsis.[3]

Because T cell function is intimately involved with many aspects of the immune response, and because depression of T cell function is strongly correlated with an increased risk of nosocomial infection after surgery or trauma, we became interested in the role of the T cell in the control of bacterial translocation from the GI tract. We performed the following studies to determine what role, if any, T cell immunity plays both in the normal process of confining bacteria to the gut and in the prevention of systemic dissemination of bacteria that have translocated to the lymph nodes that drain the GI tract.

Materials and Methods

Animals

Female Swiss Webster mice, 18–22 g (Bio-Lab Corporation, St. Paul, MN) were used in experiments involving administration of cyclosporine (CSA), anti-L3T4 antibody, and antithymocyte globulin (ATG) alone. Female BALB/c mice, 18 to 22 grams, (Department of Laboratory Medicine and Pathology mouse colony, University of Minnesota, Minneapolis, MN) were used in the experiments combining ATG and IL-2 administration with *E. coli* C25 monoassociation. Congenitally athymic nude (nu/nu) and heterozygous (nu/+) BALB/c mice, 8–11 weeks of age, were obtained from Life Sciences, Jacksonville, FL. Germ-free, 18–22 g, female BALB/c nude and heterozygous mice were housed and treated at the University of Wisconsin Gnotobiotic Laboratory, Madison, WI.

Bacteriologic Methods

After death, a swab culture of the peritoneal surface was taken and then the mesenteric lymph nodes (MLN), and, when indicated, the spleen and liver, were excised aseptically. The cecum was then removed, weighed, and transferred immediately to an anaerobic chamber (Forma Scientific, Marietta, OH). The MLN, spleen, and liver were homogenized with autoclaved glass stoppers in brain-heart infusion broth (Difco Laboratories, Detroit, MI) (MLN in 2 mL; spleen and liver in 4 mL). Two hundred microliters of the homogenate was plated in duplicate on 5% sheep blood agar (DiMed Inc, St. Paul, MN) and incubated at 35 C for 48 hours, after which the number of colony forming units (CFU) present per organ was determined. The peritoneal swab was incubated at 35° in 4 mL of brain-heart infusion broth for 24 hours following which 200 μL was plated in duplicate on 5% sheep blood agar and incubated at 35 C for 24 hours. Ceca were homogenized in 9 mL of prereduced Hank's balanced salt solution (Gibco Laboratories, Grand Island, NY). After serial dilution, 20 μL of each dilution was plated on each of the following media: (1) eosin-methylene blue agar (Difco) for enumeration of facultative gram-negative bacilli; (2) colistin-nalidixic acid agar (Difco) for enumeration of aerobic and facultative gram-positive bacteria; (3) Wilkins-Chalgren agar (Difco) supplemented with 0.1 mg/mL of gentamicin for enumeration of strictly anaerobic bacteria, and, where appropriate; and (4) nutrient agar (Difco) supplemented with 0.1 mg/mL of streptomycin sulfate (Sigma Chemical Co., St. Louis, MO) for enumeration of *E. coli* C25. After incubation for 24–48 hours, plates were read and total CFU/g of cecal weight was determined.

Gut Monoassociation with E. Coli *C25*

Mice were intestinally decontaminated by adding 2 mg/mL of streptomycin (Sigma) and 2 mg/mL of bacitracin (Sigma) to their drinking water for 4 days. An overnight culture of streptomycin-resistant *E. coli* C25 (provided by Dr. Rodney Berg, LSU Medical Center, Shreveport, LA) in brain-heart infusion broth (10^9 CFU/mL) was then added to the antibiotic-containing drinking water in a 1:1 dilution. Mice were killed after 48 hours of exposure to *E. coli* C25. In separate experiments, germ-free nude and heterozygous mice were orally inoculated with *E. coli* C25 without prior antibiotic treatment and 48 hours later were transferred by overnight air freight to our laboratory in shipping containers designed to maintain gonotobiotic conditions. The peritoneum, MLN, spleen, and liver were then cultured as described above.

Immunosuppressive Agents

Cyclosporine (CSA; Sandoz, Basel, Switzerland, 100 mg/mL) was diluted in olive oil to the desired concentration and administered subcutaneously in the flank once a day. CSA whole blood levels were determined by high pressure liquid chromatography by the Clinical Chemistry Laboratory, University of Minnesota Hospitals, Minneapolis, MN.

Anti-L3T4 antibody was derived from the GK1.5 monoclonal cell line (ATCC-TIB 507) from which antibody-rich supernatant was harvested and stored at −70 C. Aliquots were thawed just prior to use, and 0.5 mL of undiluted antibody supernatant or media control was injected daily into the dorsal tail vein. To determine the per cent of L3T4-positive cells remaining after 14 days of treatment, pooled cervical, axillary, inguinal, and MLN single-cell suspensions from three control and three L3T4-treated mice were incubated with anti-L3T4 antibody (1:2 dilution of monoclonal cell culture supernatant) and then counterlabeled with a 1:50 dilution of fluorescein-labeled antimouse immunoglobulin antibody (Cappel Laboratories, West Chester, PA) and then subjected to fluorescent activated cell sorter analysis to determine the percentage of L3T4-positive cells. The

ND = not done.

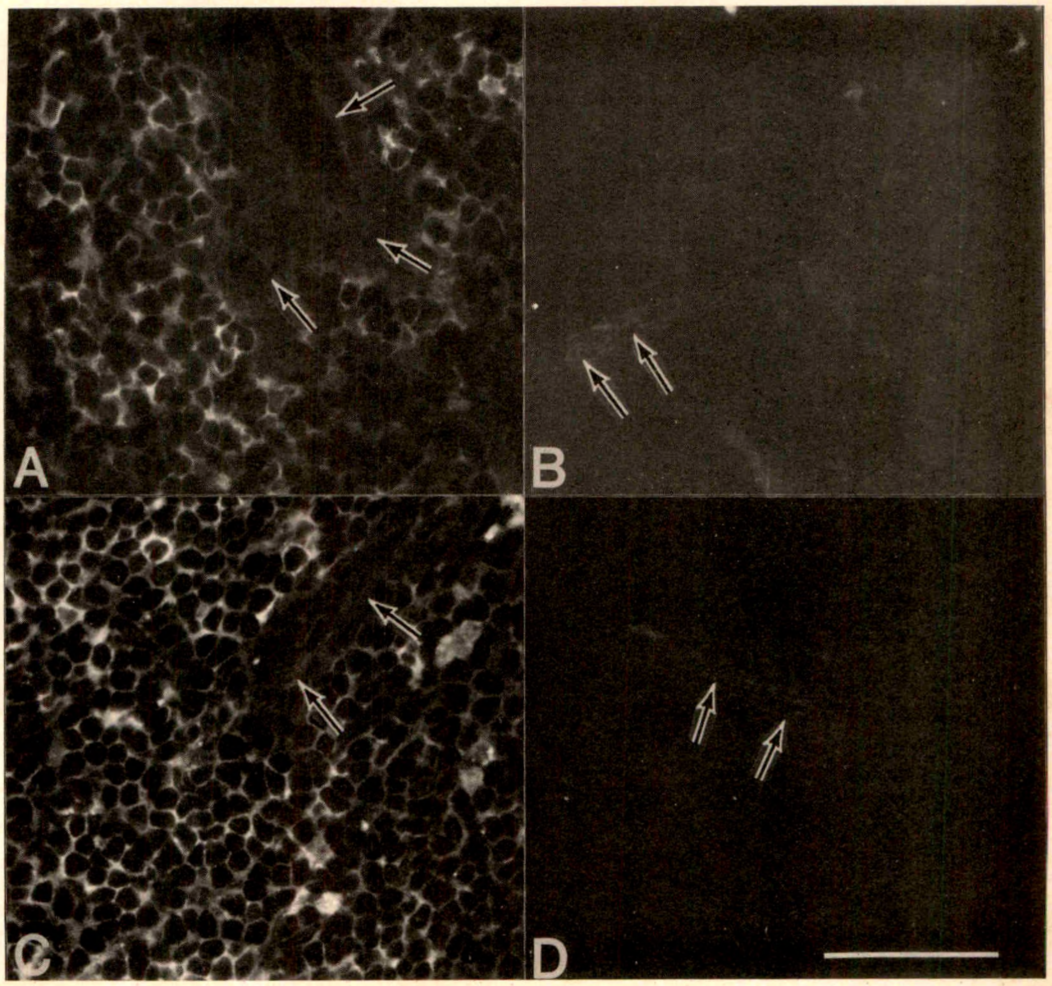

FIG. 1A–D. Frozen sections of spleen after staining with anti-Thy 1 (*A* and *B*) and with anti-Lyt 2 (*C* and *D*) (control: *A* and *C;* ATG-treated: *B* and *D*) demonstrating complete depletion of these cells. Staining with anti-L3T4 and anti-Lyt 2 antibodies also showed a complete absence of these T cell phenotypes. Scale bar represents 50 μm.

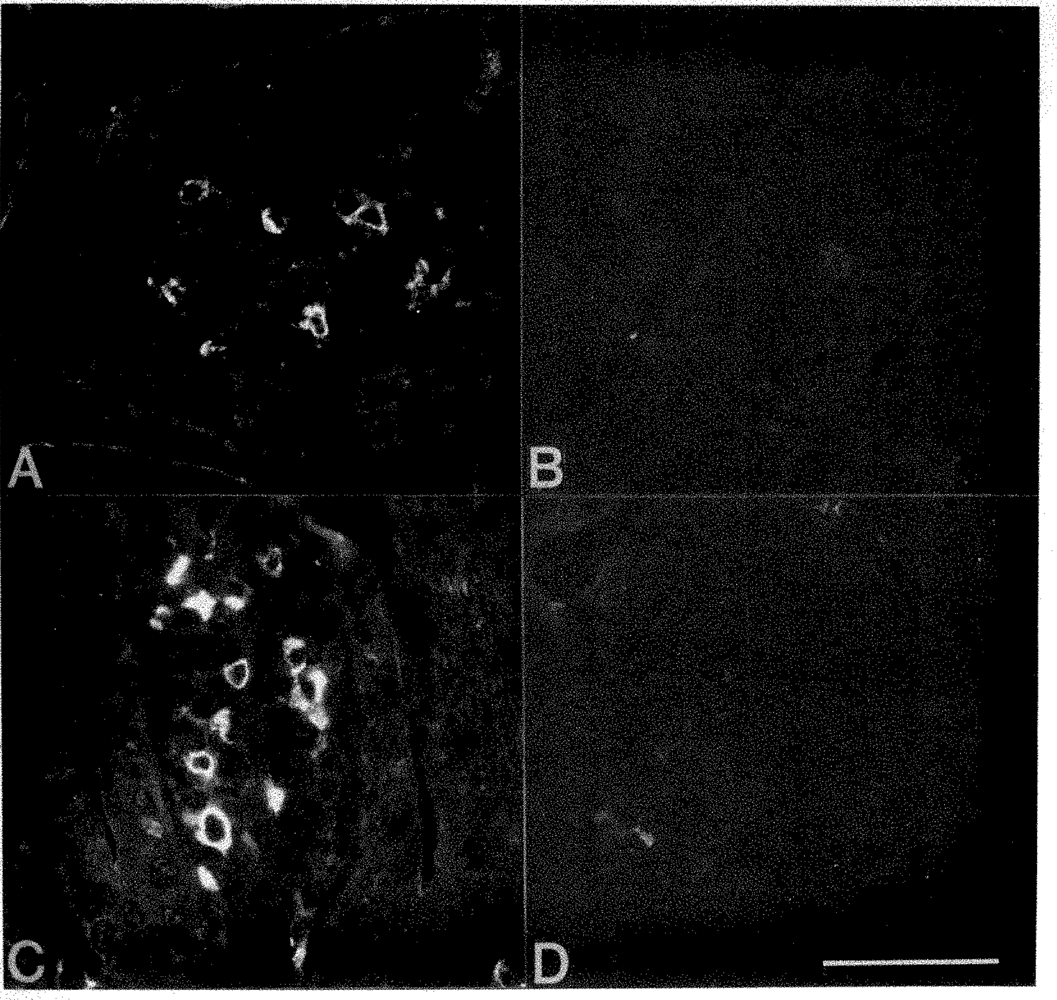

FIG. 2A–H. Frozen sections of small intestine after staining with anti-Thy 1 (*A* and *B*), anti-Lyt 1 (*C* and *D*), anti-L3T4 (*E* and *F*), and anti-Lyt 2 (*G* and *H*) (control: *A*, *C*, *E*, and *G*; ATG treated: *B*, *D*, *F*, and *H*, demonstrating complete depletion of these T cell phenotypes from the small intestine). Scale bar represents 50 μm.

average number of L3T4-positive cells remaining was expressed as a per cent of those found in control mice.

ATG (provided by Richard Condie, Director, Minnesota ALG Program, ALG Laboratories, Minneapolis, MN) is a pooled polyclonal IgG preparation derived from the immunization of horses with mouse thymocytes. The antibody was diluted in normal saline to the desired concentration, and 0.5 mL was administered intravenously (I.V.) daily via the dorsal tail vein.

IL-2 is a purified recombinant human lymphokine obtained from Cetus Corporation, Emoryville, CA. Appropriate dilutions were made in Hank's balanced salt solution without calcium or magnesium and administered intraperitoneally in a volume of 0.25 mL.

Immunofluorescent Antibody Studies

Tissues were snap frozen in precooled isopentane and stored at −70 C until used. Frozen tissue sections (4-μm thickness) prepared in a Lipshaw cryostat were stained using an indirect immunofluorescence technique previously described in detail.[4] Briefly, sections were fixed with acetone, washed in phosphate-buffered saline, and then reacted with an appropriately diluted monoclonal antibody and then reacted sequentially with the following: (1) affinity isolated fluoresceine isothiocyanate (FITC) F(ab′)2 conjugated goat-antirat IgG (H and L); (2) affinity isolated (FITC) F(ab′)2 rabbit antigoat IgG (H and L); and (3) p-phenylenediamine to retard fluorescence fading. FITC conjugated antibodies were absorbed with mouse serum prior to use. For each tissue, control sections were prepared as described above, omitting application of the monoclonal antibody.

Rat monoclonal antibodies were obtained from the following sources: anti-Thy 1 was obtained from Boehringer, Indianapolis, IN; anti-Lyt 1 (CD5) (53-7.3) and anti-Lyt 2 (CD8) (53-6.7) were from Becton Dickinson, Mountainview, CA; and anti-L3T4 (CD4) (GK1.5) was from ATCC. Antirat antibodies were from Pel-Freeze, Rogers, AR, and antigoat antibodies were from Cooper, Malvern, PA.

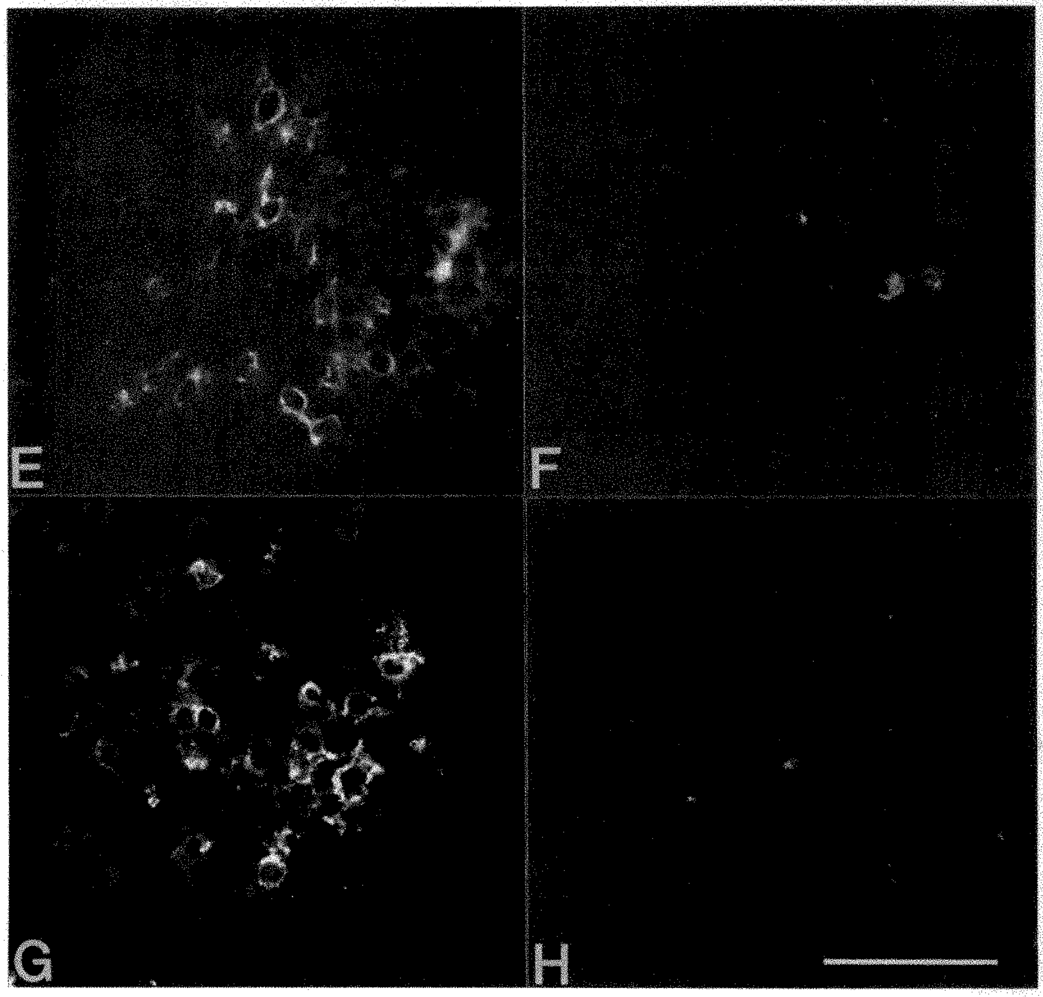

FIG. 2. (*Continued*)

Results

Effect of Suppression of Cell-mediated Immunity on Translocation in Immunocompetent Mice with a Normal Gut Flora

The first series of experiments was done to evaluate the ability of several T cell specific immunosuppressive agents to induce translocation from the gut to the MLN of Swiss Webster mice with a stable GI flora. In our laboratory, these mice exhibit a spontaneous translocation rate to the MLN of 0–10%. We first attempted to specifically suppress T-helper cell function through the use of CSA and anti-L3T4 antibody. CSA, which inhibits T-helper cell production of IL-2 and gamma interferon,[5] was administered daily in doses of either 10 mg/kg (a dose approximating that used for clinical organ transplantation) or 50 mg/kg (a more toxic dose). Control animals received olive oil devoid of CSA. On day 14 the average CSA whole blood level (taken 24 hours after the last dose) as determined by high pressure liquid chromatography was 160 ± 19 and 704 ± 67 mcg/liter (N = 3), respectively. Cultures of the MLN on days 7 and 14 demonstrated that translocation was not induced by CSA, despite moderate to high whole blood CSA levels (Table 1).

L3T4 is a cell surface molecule on mouse T-helper cells, which, through its interaction with class II major histocompatability antigens, facilitates recognition of foreign antigens.[6] Anti-L3T4 monoclonal antibody, when given *in vivo*, depletes the blood, spleen, and lymph nodes of L3T4 positive cells by 75–90% at 48 hours and 1 mg/wk can sustain a <90% reduction indefinitely.[7] In this experiment, 0.5 mL of undiluted hybridoma supernatant was administered I.V. daily for 14 days. Fluorescent activated cell sorter analysis of peripheral lymph node cells on day 14 demonstrated an average reduction of L3T4-positive cells of 75%. Cultures of the MLN on days 7 and 14 demonstrated that depletion of T-helper cells also failed to induce translocation (Table 1).

TABLE 2. *Incidence of Translocation of Indigenous GI Bacteria to the MLNs, Spleen, Liver, and Peritoneal Cavity of Athymic (Nude) Mice and Heterozygous (Thymic) Littermates*

	Site of Bacterial Translocation			
Type of Mouse	MLN	Spleen	Liver	Peritoneal Cavity
Heterozygote	2/20	0/20	0/20	0/17
Nude	0/18	1/18	0/17	1/16

Values are given as no. of mice with translocation of indigenous bacteria/total no. of mice.

TABLE 4. *Effect of ATG on the Incidence of* E. coli *C25 Translocation to Various Organs in Mice Monoassociated with* E. coli *C25**

	No. of Organs with Translocation of *E. coli* C25/Total No. of Mice			
Treatment	MLN	Spleen	Liver	Peritoneal Cavity
Monoassociation alone (control)	8/8	1/8	0/8	1/8
Monoassociation + ATG	8/8	0/8	0/8	ND

* BALB/c mice with a conventional cecal microflora were gut decontaminated for 4 days with oral bacitracin and streptomycin sulfate and were then orally monoassociated with *E. coli* C25 for 2 days; 3 mg/d of ATG was given over this 6-day period, and the organs were cultured on day 7.

Since neither T-helper cell inhibition (CSA) nor depletion (anti-L3T4 antibody) induced translocation, we next sought to more broadly deplete the animals of T cells with ATG. In our laboratory, when used as the sole immunosuppressive agent in mice, four 0.5 mg doses of ATG prevent rejection of skin grafts across major histocompatability barriers for an average of 25 days. One, three, and six mg of ATG was given I.V. daily over 7 days at which time the MLN were cultured. To assess the degree of T cell depletion induced by ATG, sections of the spleen, MLN, and small intestine of control animals and those given 3 mg ATG/day (N = 3) for 7 days were examined by immunofluorescent microscopy using fluorescein-labeled monoclonal antibodies to the cell surface antigens Thy 1, Lyt 1, L3T4, and Lyt 2 (Figs. 1 and 2). These studies demonstrated that this dose of ATG completely depleted these T cell phenotypes from the spleen and small intestine. Identical results were obtained from spleens stained with anti-L3T4 and anti-Lyt 2 and for MLN stained with anti-Thy 1, anti-Lyt 1, anti-L3T4, and anti-Lyt 2. To ensure that the administered ATG was not simply binding *in vivo* to the cell surface antigen and therefore blocking the binding of the fluorescein tagged monoclonal antibodies, sections of spleen from control animals were exposed to a 1:10,000 dilution of ATG and then stained with a fluorescein-labeled monoclonal antihorse-Ig antibody. Sections of spleen from ATG treated animals were stained only with the antihorse-Ig antibody. Sections from control animals demonstrated intense fluorescence whereas those from ATG-treated animals had no fluorescence (not shown), demonstrating that actual depletion of T cells did occur. However, despite such a profound depletion of T cells from both the systemic T cell pool and the GALT, a significantly increased incidence of translocation was not induced at any of the doses of ATG used (Table 1).

Cecal flora studies showed no effect of CSA, anti-L3T4, or ATG on the number of gram-positive, gram-negative, or anaerobic bacteria per gram of cecum (data not shown).

Translocation of Indigenous Gastrointestinal Bacteria in Nude Mice

To assess whether T cell-deficient nude mice have an intrinsic defect in the ability of their GI tract to prevent translocation, the MLN, spleen, liver, and peritoneum were cultured in heterozygous (nu/+) and nude (nu/nu) littermates without prior intestinal flora manipulations. Table 2 shows that translocation of indigenous gut bacteria to the MLN, liver, spleen, or peritoneum in either heterozygous or nude mice was not occurring. However, an unexpected finding was that the cecal flora differed quantitatively from that found in Swiss Webster mice of comparable age (Table 3). The normal level of facultative gram-negative bacteria was significantly lower in the heterozygous and nude mice compared to the higher level observed in the Swiss Webster mice. Total anaerobic and gram-positive bacteria, however, were similar. This may partially account for the lack of translocation of gram-negative bacteria in the immunodeficient nude mice.

TABLE 3. *Average Log_{10} ± SE Viable Bacteria per Gram of Cecum in Conventionally Reared Swiss Webster Mice, in Balb/c T Cell-deficient (Nude) mice, and Their Heterozygous (Thymic) Littermates*

Type of Mouse	Strict Anaerobes	Aerobic and Facultative Gram-positive Bacteria	Aerobic and Facultative Gram-negative Bacilli	Average Cecal Weight (g)
Heterozygote (N = 4)	10.3 ± 0.3	7.4 ± 0.7	3.7 ± 1.0	0.72 ± 0.07
Nude (N = 4)	9.7 ± 0.5	7.4 ± 0.4	3.7 ± 1.0	0.56 ± 0.10
Swiss Webster (N = 4)	9.2 ± 1.4	6.9 ± 0.6	6.7 ± 1.7	0.50 ± 0.20

TABLE 5. *Effect of ATG on the Cecal Bacterial Counts of Mice Monoassociated with* E. coli *C25**

	Average Log_{10} ± SE Cecal Bacteria per Gram (N = 4)			
Treatment	*E. coli* C25	Strict Anaerobes	Aerobic and Facultative Gram-positive	Average Cecal Weight (g)
Monoassociation alone (control)	9.7 ± 0.3	0	1.0 ± 0.1	1.0 ± 0.1
Monoassociation + ATG	9.8 ± 0.1	0	1.03 ± 0.1	1.0 ± 0.1

* BALB/c mice with a conventional cecal microflora were gut decontaminated for 4 days with oral bacitracin and streptomycin sulfate and were then orally monoassociated with *E. coli* C25 for 2 days; 3 mg/d of ATG was given over this 6-day period, and the organs were cultured on day 7.

Effect of T Cell Deficiency on the Translocation of E. coli *C25*

Since neither T cell inhibition (CSA) or depletion (anti-L3T4, ATG, nude mice) induced translocation in mice with a normal intestinal flora, the influence of T cell immunity on translocation was next examined in mice monoassociated with *E. coli* C25. By decontaminating the GI tract with oral bacitracin and streptomycin for 4 days and then adding streptomycin-resistant *E. coli* C25 to the drinking water for 2 days, intestinal overgrowth of *E. coli* C25 to abnormally high levels occurs. Such intestinal overgrowth (monoassociation) leads to translocation of *E. coli* C25 to the MLN in 80–100% of animals but not to other organs.[8] Therefore, in animals with intact host defenses, the MLN is the point at which translocation is contained. To test the hypothesis that depression of T cell immunity would impair the ability of the MLN to contain translocating bacteria, immunocompetent BALB/c mice were given 3 mg/d of ATG during the 6-day period of monoassociation with *E. coli* C25 (total of six doses). Control mice received saline injections. On day 7 the MLN, spleen, liver, and peritoneum were cultured and the incidence of translocation of *E. coli* C25 to each organ was determined. Immunofluorescent antibody studies of the spleen, MLN, and intestine (N = 3 for control and ATG-treated mice) were also repeated and showed the same degree of depletion of Thy 1, Lyt 1, L3T4, and Lyt 2 cells as shown in Figures 1 and 2.

Table 4 shows that treatment with ATG had no influence on the incidence of translocation of *E. coli* C25 to the MLN when compared with control animals. In addition, complete depletion of the systemic and GALT T cell pool did not promote spread of *E. coli* C25 beyond the MLN to the spleen, liver, or peritoneum. Since the cecal levels of *E. coli* C25 were the same in both control and ATG-treated animals (Table 5), both groups had an equal susceptibility to translocate.

To further evaluate the ability of the suppression of T cell function to promote spread of translocating bacteria, we next studied BALB/c nude mice with a normal gut flora (conventional) and germ-free BALB/c nude mice. Conventional BALB/c nude mice and their heterozygous littermates were monoassociated with *E. coli* C25 as above. Cultures of the MLN, spleen, liver, and peritoneum on day 7 again showed the expected translocation of *E. coli* C25 to the MLN, but again, no spread of *E. coli* C25 to the spleen, liver, or peritoneum was observed (Tables 6 and 7).

Germ-free mice, because they are isolated from the external environment from birth, have a sterile GI tract. Therefore, oral inoculation with *E. coli* C25 without prior antibiotic treatment leads to intestinal overgrowth and translocation to the MLN in 90–100% of the animals. Although translocation to the MLN reliably occurs in immunocompetent germ-free mice, spread of *E. coli* to the spleen, liver, or peritoneum does not.[9] To assess whether GALT T cell immunity is important in the generation of a protective immune barrier to the systemic escape of bacteria, germ-free nude mice and their heterozygous littermates were orally monoassociated with *E. coli* C25 for 2 days and on the third day the MLN, spleen, and liver were cultured. Despite the presence of extremely high levels of *E. coli* C25 in the ceca of both the heterozygous and nude mice, translocation was again confined to the MLN alone (Tables 8 and 9).

Although spread of *E. coli* C25 beyond the MLN did not occur in either the ATG-treated, conventional nude,

	Average Log_{10} ± SE Cecal Bacteria per Gram			
Type of Mouse	*E. coli* C25	Strict Anaerobes	Aerobic and Faculatative Gram-positives	Average Cecal Weight (g)
Heterozygotes (N = 4)	10.8 ± 0.4	1.9 ± 2.1	4.5 ± 0.5	0.88 ± 0.02
Nude (N = 3)	10.6 ± 0.3	1.4 ± 2.4	4.7 ± 0.3	0.69 ± 0.14

or germ-free nude mice, a consistent finding in all three experiments was that the average number of *E. coli* C25 per MLN was higher than that in control animals (Table 10).

Effect of Treatment with Interleukin-2 on Translocation of E. coli *C25*

To examine the influence of augmented cellular immune function on bacterial translocation, BALB/c mice were monoassociated with *E. coli* C25 and during the 2 days of oral exposure to *E. coli* C25, IL-2 was given intraperitoneally either every 8 hours (25,000 units per dose, total of six doses) or as a single bolus dose of 150,000 units on either the first or second day of exposure to *E. coli* C25. Cultures of the MLN showed that IL-2 significantly decreased the overall incidence of translocation of *E. coli* C25 to the MLN compared to control animals only when given every 8 hours. Giving IL-2 as a bolus of 150,000 had no effect on either the incidence or number of *E. coli* C25 per MLN (Table 11).

Discussion

Despite the continuous exposure of its epithelial surface to the hostile microbial environment of its lumen, the GI tract maintains a highly effective barrier to the systemic entrance of gut microbes. Since the composition of the normal cecal and ileal flora consists of approximately 10^{10} anaerobic bacteria/g, 10^{5-7} aerobic and facultative gram-negative bacteria/g, and 10^{6-8} aerobic and facultative gram-positive bacteria/g, this barrier must be relatively nonselective and indifferent to the extreme degree of microbial and antigenic diversity. On the other hand, it must also be capable of selectively responding to microbial pathogens that use the gut as their portal of entry.

The GI tract's defense against translocation appears to involve two components. The first is a nonspecific mechanical and chemical barrier. This is composed of the lining mucosal cells with their tight intercellular junctional complexes, the mucus layer, which overlays the epithelium, and, finally, the indigenous gut bacteria, particularly the anaerobic component. The large population of anaerobes normally present appears to play a particularly important role in the normal control of other resident gut bacteria.[10] Due to their high numbers, they prevent overgrowth of other gram-negative and gram-positive bacteria within the intestine and, by secreting large amounts of short chain fatty acids within the mucus layer overlying the epithelium, they inhibit the adherence of other potential pathogens, such as *C. albicans.*[11]

The second component of the GI tract's defense system is the immunologic defense or gut-associated lymphoid tissue (GALT). The GALT is composed of: (1) a diffuse population of T-helper cells, B cells, and plasma cells located throughout the lamina propria of the intestine, and (2) Peyer's patches (in the small intestine) and lymphoid nodules (in the small and large intestine). Although Peyer's patches and lymphoid nodules differ in size, both are histologically and functionally similar.[12] Their luminal surface is lined by a specialized phagocytic cell referred to as an M (for microfold) cell.[13] Below the M cell is a population of macrophages and below these are lymphoid follicles that are composed of T and B cells (Fig. 3).

By virtue of their unique structure, Peyer's patches and lymphoid nodules serve as the focal point for the induction of immune responses to foreign antigens. After uptake of a foreign antigen by an M cell, it is transferred without alteration to the underlying macrophages. The macrophages are thought to process the antigen, present it to the lymphocytes of the surrounding lymphoid nodules, following which antigen-specific T and B lymphoblasts are generated. These cells leave the intestine, pass through the systemic circulation, and then *home* to the lamina propria of the intestine where they mature to T-helper/inducer cells, B cells, and plasma cells, which are committed to the secretion of antigen-specific IgA into the intestine (Fig. 4).[12] Despite the presence of such an elaborate system for the generation of luminal IgA, the presence of IgA does not appear to be essential for the maintenance of an immunologic defense against translocation of indigenous gut bacteria because patients with selective IgA deficiency do not have an increased incidence of infections caused by the bacteria normally found in the gut.[14] However, IgA is extremely important in the defense against pathogens, which have the gut as their target organ (*e.g.*, *Shigella* sp).[15]

Despite the presence of the both the mechanical/chemical barrier and the GALT, systemic translocation of indigenous gut bacteria does occur under a variety of circumstances. Escape of bacteria to the liver via the portal venous system appears to occur only when there has been an extreme insult (such as intestinal ischemia) to the integrity of the intestine.[16] However, translocation of bacteria from the gut lumen to the draining mesenteric lymph nodes can occur without direct damage to epithelial integrity. Van der Waaij et al. first noted in 1972 that the administration of oral antibiotics to mice would lead to translocation of bacteria to the MLN.[17] Since then it has been shown that disruption of the normal gut flora by the administration of selective antibiotics allows overgrowth of the remaining bacteria within the intestine and that such bacterial overgrowth often leads to translocation to the MLN.[18]

Translocation of indigenous gut bacteria to the MLN also occurs after a variety of other insults, such as following the administration of lipopolysaccharide,[19] after large body surface area burns,[20] with physical disruption of the gut mucosal barrier,[21] and after the administration of prednisone and cyclophosphamide.[22] Many of these situations have as part of their pathophysiology alterations in intestinal blood flow (LPS, burns with loss of fluid) or cellular function (cyclophosphamide), both of which can damage the integrity of the GI tract. Although the maintenance of an intact epithelial layer is critical in preventing translocation, the role of the GALT, in particular the role of T cell immunity, in the defense against translocating bacteria is unknown.

In these studies we first sought to determine whether T cell dysfunction would induce translocation of indigenous gut bacteria in mice with a conventional cecal flora. Neither T-helper cell inhibition (CSA) or depletion (anti-L3T4 antibody), nor depletion of other T cells such as Lyt 2+ cells (T cytotoxic/suppressor cells) with ATG induced translocation. Because these alterations of T cell function were on a short-term basis (over a maximum of 14 days), the incidence of translocation to the

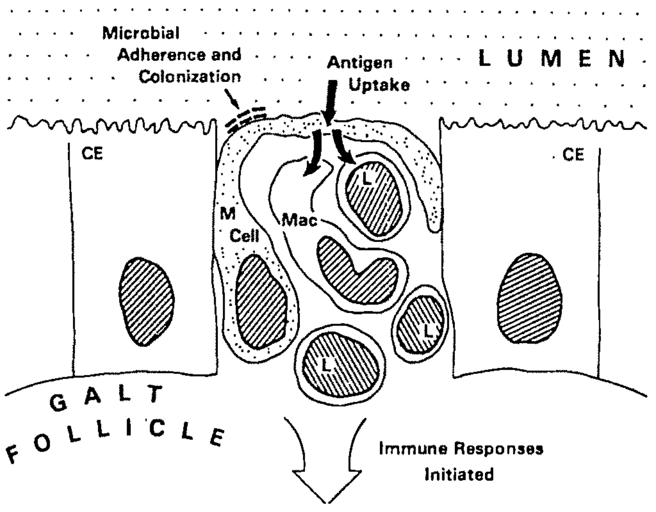

FIG. 3. Peyer's patch in the intestine. An M cell, the surface of which is in contact with the contents of the intestinal lumen, is surrounded by subepithelial macrophages (Mac) and by lymphocytes (L). M cells are important sites of antigen and microbe uptake by the GALT.

MLN, liver, and spleen in T cell-deficient nude mice was determined and was also found to be essentially zero. This, combined with the experiments utilizing CSA, anti-L3T4 antibody, and ATG, clearly demonstrates that suppression of T cell function or number has little effect on the ability of the GI tract to prevent translocation in animals in which gut microflora is unaltered and in which there is no other predisposition to translocate. It would appear then that in animals without other predisposing factors to translocate (such as bacterial overgrowth or disruption of epithelial integrity), T cell immunity is not of primary importance in the prevention of bacterial translocation.

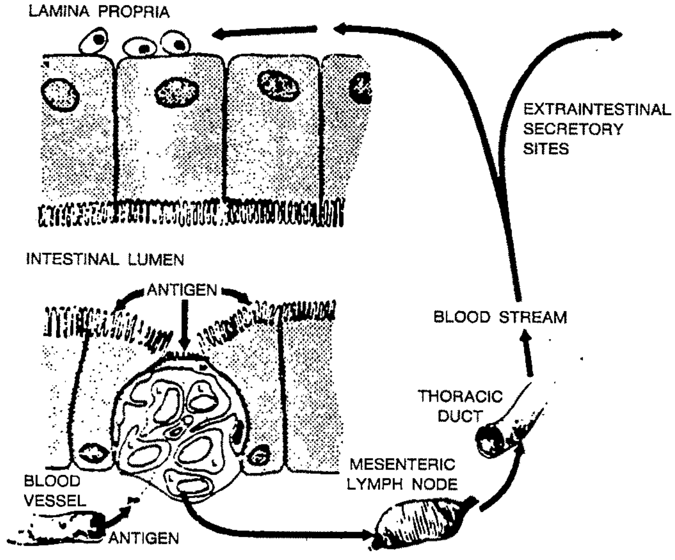

FIG. 4. Schematic representation of the induction of an immune response within the GALT. After antigen is processed by a Peyer's patch, antigen-specific T and B lymphoblasts enter the systemic circulation via the thoracic duct and then home to the lamina propria of the intestine. There they mature to antigen-specific T cells, B cells, and plasma cells, which are committed to the production of IgA for secretion into the intestinal lumen.

Under most of the experimental circumstances in which translocation occurs, it has been found that bacteria translocate most often to the MLN.[9] Only with severe insults to the intestine (ischemia or a combination of bacterial overgrowth and 20% body surface area burns)[20] will bacteria seed systemic sites such as the liver and spleen. Since, in the absence of direct intestinal damage, bacterial translocation is limited to the MLN, it appears that local factors within the MLN (for example T cell lymphokines) may exert a significant influence on the containment of bacteria that are translocating to the MLN.

To examine this question, a model of translocation was used which reliably induces translocation (in immunocompetent mice) of bacteria only to the MLN and rarely (<10%) to the liver or spleen. Monoassociation of (1) immunocompetent mice treated with 3 mg ATG/d for 6 days, (2) T cell-deficient nude mice with a conventional gut flora prior to monoassociation with *E. coli* C25, and (3) T cell-deficient nude germ-free mice with *E. coli* C25 yielded an equivalent incidence of translocation to the MLN. However, in all three experiments the MLN continued to be the site at which translocating *E. coli* C25 was contained since the spleen, liver, and peritoneum were invariably sterile. These results demonstrate that the MLN does, with this degree of translocation, serve as a point where translocating bacteria are entrapped and that T cells or their secreted factors play a small role in the prevention of systemic bacterial spread.

A rather striking and consistent trend noted in these experiments, however, was that suppression of T cell function did increase the average number of viable *E. coli* C25 per MLN. Although statistical significance was not achieved in the experiment in which germ-free nude mice were monoassociated, the trend was similar. The mechanism of this increase in bacteria per MLN is unknown. Whether due to an increased rate of translocation from the intestine or due to an impairment of the microbicidal environment of the lymph node, the results suggest that defects in T cell immunity may make the MLN a focus of persistent infection when there is translocation to it from whatever cause.

Finally, the influence of T cell stimulation on the translocation of *E. coli* C25 was investigated through the systemic administration of recombinant IL-2. IL-2 is a lymphokine produced by T-helper cells that stimulates the growth of activated lymphocytes *in vitro.* When administered *in vivo* IL-2 has a variety of effects including enhancement of T helper and T cytotoxic cell reactivity to antigens,[23] reversal of several T cell immunodeficiencies in nude mice,[24,25] and the generation of cells that have the ability to lyse tumors *in vitro.*[26]

We found that a total dose of 150,000 units significantly decreased the overall incidence of translocation of *E. coli* C25 to the MLN. To be effective, it was necessary to administer the 150,000 units in divided doses of 25,000 units every 8 hours during the 2-day period of oral monoassociation with *E. coli* C25. A single bolus dose of 150,000 units either on the first or second day of *E. coli* C25 monoassociation was ineffective at reducing translocation. Since during the 2 days of monoassociation with *E. coli* C25 there presumably is continuous translocation of *E. coli* C25 to the MLN, and since the serum activity of an intraperitoneal dose of IL-2 persists for approximately 2–3 hours,[27] it is not surprising that the single bolus dose of 150,000 units was ineffective in decreasing translocation. However, since the immediate effect of the single bolus dose of 150,000 units on translocation was not tested by culturing the MLN within hours after IL-2 administration, it is possible that a decrease in the translocation of *E. coli* C25 may have been missed.

What role the *in vivo* generation of LAK cells played in diminishing translocation of *E. coli* C25 to the MLN is unknown. Although the cellular origin of LAK cells is at present unresolved, it appears that a substantial number are formed from preexisting natural killer (NK) cells.[28] To date, no studies of any possible antimicrobial activity of LAK cells have been performed, but a recent report has shown that a subpopulation of NK cells does possess phagocytic and microbicidal capabilities for the gram-positive microbe *Staphylococcus aureus.*[29] However, these same NK cells were unable to phagocytose either *E. coli* or *Pseudomonas aeruginosa.* Whether treatment with IL-2 can either expand this population of NK cells or induce them to become phagocytic for gram-negative bacteria is speculative, but given the intense degree of proliferation of LAK cells within the MLN that occurs after systemic IL-2 administration,[26] this remains a possibility.

An alternative explanation is that IL-2 may have enhanced the specific immune response to *E. coli* C25 within the GALT. Given the brief 48-hour period of exposure to IL-2, it seems unlikely that an increased secretion of IgA specific for *E. coli* C25 into the gut lumen would have occurred. However, within the MLN antigen-specific lymphocytes already exposed to *E. coli* C25 may be more rapidly induced in the presence of IL-2, and, if combined with a general increase (induced by IL-2) in the release of macrophage activating lymphokines (such as gamma interferon), there could be an increased microbicidal capacity of macrophages within the lymph node leading to increased killing of *E. coli* C25. Relevant to this concept is the recent demonstration by Holter et al. that gamma interferon and lipopolysaccharide can induce IL-2 receptors on peripheral blood monocytes and that, if subsequently exposed to IL-2, the monocytes display increased H_2O_2 activity, suggesting an increase in their microbicidal activity.[30] Regardless of the specific mechanism, it is likely that the phenomenon of decreased translocation of *E. coli* C25 after treatment with IL-2 is due to a local process within the MLN and not within the intestine since *in vivo* administration of IL-2 has been shown to have little, if any, proliferative effect on lymphocytes within the intestine.[26]

In conclusion, T cell immunity appears to have little effect on the prevention of the movement of bacteria from the gut lumen to the MLN. However, by influencing either the antibody response to translocating bacteria or the local microbicidal activity of the MLN against translocating bacteria, normal T cell function does appear to have a modest impact on the ability of the GALT to effectively deal with translocating bacteria. In a critically ill surgical patient who is receiving systemic antibiotics (the majority of which have a marked impact on the composition of the intestinal flora), combined with ileus (with its attendant stasis of gut contents), malnutrition (with impaired ability of the gut epithelial cells to renew themselves), and shock or low flow states (with reduction in blood flow to the intestines), the function of the host's immune system, particularly T cell function within the lymph nodes draining the gut, may assume importance in the ability to control translocating gut bacteria.

Further Evidence that Accelerated Muscle Protein Breakdown During Sepsis Is Not Mediated by Prostaglandin E_2

PER-OLOF HASSELGREN, M.D., PH.D., BRAD W. WARNER, M.D., ROBERT P. HUMMEL III, B.A., J. HOWARD JAMES, B.S., CORA K. OGLE, PH.D., and JOSEF E. FISCHER, M.D., F.A.C.S.

Prostaglandin E_2 (PGE_2) reportedly increases protein breakdown in skeletal muscle. The role of PGE_2 for accelerated muscle proteolysis during sepsis, however, is controversial. In this study, the effect of the prostaglandin synthesis inhibitor indomethacin on PGE_2 release and protein breakdown in skeletal muscle from nonseptic and septic rats was evaluated. Sepsis was induced in male Sprague-Dawley rats (40–60 g) by cecal ligation and puncture (CLP). After 16 hours the extensor digitorum longus (EDL) and soleus (SOL) muscles were dissected with intact tendons and incubated in an oxygenated medium, and the release of tyrosine (protein breakdown) and PGE_2 into the incubation medium was determined. Paired muscles were incubated in the absence or presence of indomethacin (3 μmol/L or 6 μmol/L). In some experiments the effect of indomethacin was investigated in the presence of different concentrations of insulin (1, 10, or 100 mU/mL) since previous reports suggested an interaction between insulin and prostaglandins on protein turnover in skeletal muscle. In other experiments muscles were incubated in a flaccid or stretched state, which is known to influence the metabolic response to different substances. Protein breakdown rate was 0.210 ± 0.013 and 0.492 ± 0.025 μmol Tyr/g × 2 hours in EDL from nonseptic and septic rats, respectively ($p < 0.01$). The corresponding values for SOL were 0.480 ± 0.037 and 0.712 ± 0.039 μmol Tyr/g × 2 hours ($p < 0.01$). Addition of indomethacin to the incubation medium reduced PGE_2 release from 29.1 ± 3.1 to 6.8 ± 0.7 ng/g × 2 hours in nonseptic SOL and from 50.6 ± 10.4 to 5.6 ± 0.7 ng/g × 2 hours in septic SOL. Protein breakdown rate in SOL and EDL from sham-operated or septic rats was unaffected by indomethacin, both when muscles were incubated in a flaccid or stretched state, and when they were incubated in the presence or absence of insulin. The present results do not suggest a role of PGE_2 for accelerated muscle proteolysis in the present experimental septic model.

From the Department of Surgery, University of Cincinnati Medical Center, Cincinnati, Ohio

THE ROLE of prostaglandin E_2 (PGE_2) for accelerated muscle proteolysis during trauma and sepsis is controversial, with various laboratories reporting differing results. Thus, while some authors reported data suggesting a link between PGE_2 synthesis and increased muscle protein breakdown,[1-3] other studies demonstrated that protein degradation remained elevated in postinjury skeletal muscle despite inhibition of prostaglandin synthesis by indomethacin.[4,5]

In a recent study from this laboratory, the accelerated protein breakdown in incubated soleus (SOL) muscles from septic rats was unaffected by indomethacin despite a 50% reduction in prostaglandin synthesis,[6] and it was suggested that increased muscle proteolysis during sepsis is not mediated by PGE_2.

Recent reports demonstrated an interaction between prostaglandins and insulin on different metabolic processes in skeletal muscle,[7,8] and indomethacin affected protein turnover in gastrocnemius and plantaris muscles of rats only in the presence of insulin.[8] Since in our previous report[6] muscles were incubated in a medium without insulin, it could be argued that the failure of indomethacin to reduce protein breakdown was due to the absence of insulin in the *in vitro* system. Other *in vitro* conditions may have rendered the muscles unresponsive to indomethacin as well, for example, the fact that the muscles were incubated in a flaccid rather than stretched state,[9] and that the effect of indomethacin *in vitro* was only tested in one type of skeletal muscle, namely, the red, slow SOL muscle. Regulation of protein turnover may differ in different types of skeletal muscle, and varying responsiveness to hormones and other substances has been reported in white, fast, and red, slow muscle, respectively.[10-12]

* Seven paired muscles were incubated in the absence or presence of indomethacin (3 μmol) at each insulin concentration.

The purpose of the present study was to further test the hypothesis that accelerated protein breakdown in skeletal muscle from septic animals can be regulated by the prostaglandin synthesis inhibitor indomethacin, with special emphasis on *in vitro* conditions that may affect the responsiveness in incubated muscles. A better understanding of the role of prostaglandins for increased muscle protein breakdown is important since the use of indomethacin or other cyclooxygenase inhibitors has been proposed in the treatment of postinjury and septic catabolism.[2,13,14]

Materials and Methods

Young male Sprague-Dawley rats weighing 40–60 g were used. Rats of this size possess thin extensor digitorum longus (EDL) and SOL muscles, which facilitates oxygenation of the tissue during incubation *in vitro.*[15] Septic muscles were harvested from rats 16 hours after cecal ligation and puncture (CLP), performed as described earlier.[6] Nonseptic muscles were dissected from rats 16 hours after sham operation, namely, laparotomy and manipulation of the cecum. Animals were resuscitated with saline (5 mL/100 g body weight, subcutaneously) at the time of operation and were thereafter fasted but allowed water *ad libitum.*

Protein Degradation

The EDL and SOL muscles were dissected with intact tendons under ether anesthesia, weighed, and preincubated for 30 minutes in 3 mL of a medium consisting of Krebs-Henseleit bicarbonate buffer (pH 7.4) supplemented with 5 mmol/L glucose. The incubation medium was saturated with 0_2:CO_2 (95:5), and incubation was performed at 37 C in a shaking water bath. After preincubation, muscles were transferred to 3 mL of fresh medium containing cycloheximide (0.5 mmol/L), and rate of protein degradation was determined by measuring the amount of tyrosine released into the medium.[16,17] Tyrosine was measured with high performance liquid chromatography. In some experiments the incubation medium was supplemented with a complete amino acid mixture (with the exception of tyrosine) at normal plasma concentration, 2% defatted bovine albumin, and 5 mmol/L glucose. Muscles were routinely incubated in a flaccid state. In other experiments they were mounted on small wire frames at approximate resting length. In studies using insulin or indomethacin, the substances were present in the medium both during preincubation and incubation. Indomethacin was dissolved in 50% ethanol before it was added *in vitro.* A corresponding volume of ethanol (10 μl/mL) was added to incubation flasks containing control muscles. Contralateral muscle from the same animal always served as control.

Prostaglandin E_2

PGE_2 production by incubated muscles was determined by radioimmunoassay of PGE_2 that was released into the medium, as described previously.[6]

Statistics

Results are given as mean ± SEM. Wilcoxon's nonparametric test for paired differences was used for statistical comparisons.

Results

When nonseptic or septic SOL muscles were incubated in the absence of insulin, addition of 3 μmol/L indomethacin to the incubation medium did not significantly affect protein degradation rate (Table 1), confirming a previous report from this laboratory.[6] The concentration of indomethacin used here effectively blocked PGE_2 production by incubated muscles in previous studies[1,6] and prevented the increase in protein degradation rate induced by arachidonic acid, added *in vitro.*[1] Also, when muscles were incubated in the presence of different insulin concentrations, ranging from 1 mU/mL to 100 mU/mL, indomethacin did not affect protein degradation rate (Table 1).

Although PGE_2 release from incubated muscles was effectively blocked by indomethacin at a concentration of 3 μmol/L,[1,6] we wanted to test whether this indomethacin concentration was too low to affect protein degradation. The concentration of the substance in the incubation medium was therefore increased to 6 μmol/L, but even then protein degradation was unaffected despite a marked reduction of PGE_2 release (Table 2). The PGE_2 release rates reported here are higher than in our previous study,[6] probably due to the fact that the experiments described in Table 2 were performed with

TABLE 2. *Release of Tyrosine (μmol × gww^{-1} × 2 h^{-1}) and PGE$_2$ (ng × gww^{-1} × 2 h^{-1}) from SOL Muscles Incubated in the Presence of 100 mU/mL of Insulin with or without 6 μmol/L Indomethacin*

Results are from seven paired nonseptic and septic muscles.

P values indicate significant *versus* muscles incubated without indomethacin.

insulin in the incubation medium. The almost doubled PGE$_2$ release in septic compared with nonseptic muscle is similar to our previous report.[6]

Thus, it is not likely that previous results[6] were due to the fact that insulin was not present in the incubation medium or that the concentration of indomethacin was too low. Another reason why indomethacin did not affect protein breakdown could be that the time during which the muscles were exposed to the substance was too short. Nonseptic and septic SOL muscles were therefore incubated for 6 hours in the absence or presence of 3 μmol/L indomethacin. A linear release of tyrosine from incubated rat SOL muscles for up to 6 hours was demonstrated previously.[18] Also during this extended incubation period, indomethacin did not affect protein breakdown rate, which was 0.998 ± 0.030 and 0.999 ± 0.032 μmol Tyr × gww^{-1} × 6 h^{-1} in seven paired nonseptic SOL muscles, incubated without or with indomethacin, respectively. The corresponding values for seven paired septic SOL muscles were 1.183 ± 0.119 and 1.100 ± 0.107 μmol Tyr × gww^{-1} × 6 h^{-1} (NS).

In previous reports, muscles were in a less catabolic state if incubated in a stretched, rather than flaccid, state.[9] Perhaps more important for this study, the response to different substances *in vitro* varied, depending on whether muscles were incubated in a stretched or flaccid state.[19–21] When nonseptic or septic SOL muscles were incubated stretched to resting length, protein breakdown remained unaffected by indomethacin (Table 3).

Paired muscles were incubated in the absence or presence of indomethacin (3 μmol/L).

Numbers in parentheses indicate number of paired observations.

Most incubations in the present study and all incubations in our previous report[6] were performed with an unsupplemented medium. Since the response to various substances may be different if muscles are incubated under more physiologic conditions, experiments were performed in which muscles were incubated in the presence of an amino acid mixture and albumin. Results showed that protein breakdown rates were generally lower in this supplemented medium (Table 4 [compare with Table 1]). Also under these conditions, protein breakdown remained unaffected by indomethacin, both in nonseptic and septic muscle (Table 4).

Protein turnover rates are different in different types of skeletal muscle,[17] and the response to various conditions and substances may be different in the red, slow SOL muscle and the white, fast EDL muscle.[10–12] In the present study, we therefore also tested the effect of indomethacin on protein degradation in incubated EDL muscles from nonseptic and septic rats. Again, protein breakdown rate was not significantly altered by indomethacin (Table 5).

Discussion

The present study demonstrated that accelerated tyrosine release in incubated skeletal muscle from septic rats was not affected by indomethacin, despite the fact that PGE$_2$ production was markedly reduced. The results confirm a recent study from this laboratory,[6] and suggest that muscle protein breakdown in the present exper-

imental model is not regulated by prostaglandins. In nonseptic muscle as well, protein degradation was unaffected by indomethacin, similar to previous reports in which basal degradative rates were not determined by prostaglandin levels in control muscles.[1]

In the present study, the effect of indomethacin *in vitro* on protein breakdown was tested in muscle incubated under different conditions known to influence the response to indomethacin and other substances. Protein breakdown was unaffected by indomethacin when muscles were incubated in the absence or presence of different concentrations of insulin and when they were incubated in a flaccid or stretched state. Incubation in different types of medium did not render protein breakdown sensitive to indomethacin, and the substance failed to reduce proteolysis both in the red SOL and the white EDL muscle. Although the present results strongly suggest that accelerated protein breakdown in septic muscle is not mediated by prostaglandins, an alternative interpretation may be that PGE_2 is important in the initiation of proteolysis but not in its maintenance. This is less likely, however, since pretreatment of rats *in vivo* with indomethacin 45 minutes before induction of sepsis[6] or 2 hours before burn injury[4] did not affect muscle protein breakdown despite significant inhibition of PGE_2 production. Proteolysis in normal muscle incubated in the presence of plasma from septic animals remained elevated despite the fact that indomethacin was present in the incubation medium from the start of incubation,[6] further suggesting that PGE_2 is not important for initiation or maintenance of proteolysis.

The concept of a role of PGE_2 for increased muscle proteolysis in trauma and sepsis originated from studies in which the addition of PGE_2 to incubated muscles stimulated protein breakdown.[1] In subsequent experiments, administration *in vitro* of leukocytic pyrogen enhanced PGE_2 production and protein degradation in incubated muscles, and both effects were abolished by indomethacin.[2] When indomethacin was administered to rats, urinary excretion of nitrogen decreased, and although the results were interpreted as indicating impaired renal function,[22] it is possible that the data reflected reduced protein breakdown as well. In other studies, muscle protein breakdown increased following intra-arterial infusion of PGE_2.[3] Thus, it is obvious that high levels of PGE_2 can induce muscle protein breakdown. However, there is no convincing evidence in the literature that muscle protein degradation is regulated by prostaglandins in any physiologic or pathologic condition despite the fact that prostaglandin synthesis was increased in various conditions characterized by accelerated muscle proteolysis.[5,6] On the contrary, several lines of evidence argue against a role of prostaglandins for the regulation of muscle proteolysis.

In addition to the present study and a recent report from this laboratory,[6] other investigators as well failed to reduce postinjury catabolism despite inhibition of prostaglandin synthesis. Administration of indomethacin to burn-injured rats did not affect the elevated protein breakdown rate in incubated epitrochlearis muscle despite the fact that PGE_2 release by the muscles was reduced from 22.1 to 8.5 ng/g × 2 h.[4] In the same study, indomethacin added *in vitro* (3 μmol/L) to incubated muscles from burned rats decreased PGE_2 release but did not affect the high rate of protein degradation. Similar results were observed in a more recent study in which proteolysis in incubated SOL muscles from rats following burn injury remained elevated in spite of 90% inhibition of PGE_2 production with aspirin or indomethacin.[5] In contrast to these studies, a recent report demonstrated inhibited muscle wasting and cathepsin B activity in EDL and SOL muscles from septic rats treated with indomethacin.[23] However, since no measurements of protein turnover rate or muscle protein content were made in that study, it is not known if protein degradation was affected by indomethacin. When the cyclooxygenase inhibitor ibuprofen was administered to healthy volunteers who were treated with endotoxin, fever and flu-like symptoms were reduced and the ACTH and cortisol release were blocked.[24] In contrast, the increased oxygen consumption and several other components of the acute phase response were unaffected by ibuprofen, suggesting that metabolic alterations during endotoxemia may persist despite effective blockade of prostaglandin synthesis.

Administration of insulin *in vivo*[8] or *in vitro*[25] increased prostaglandin synthesis and concentration in skeletal muscle tissue. From other studies it is well known that insulin reduces muscle protein breakdown.[10,26-28] Reduced muscle proteolysis in the presence of high concentrations of prostaglandins, including PGE_2, does not support the concept of a role of this substance as a mediator of increased muscle protein breakdown. In the present study, septic muscles were incubated in the presence of high concentrations of insulin, two factors that probably contributed to increased tissue levels of PGE_2. In spite of this, indomethacin did not affect protein degradation rate. It should be noted, however, that the stimulatory effect of insulin on protein synthesis is probably mediated by prostaglandins. Thus, muscle concentration of $PGF_{2\alpha}$, which is known to increase muscle protein synthesis in skeletal muscle,[1] was elevated by insulin, and the insulin-induced stimulation of protein synthesis was blocked by indomethacin.[8,25]

Incubation of skeletal muscle in a stretched rather than flaccid state resulted in increased protein synthesis and reduced protein degradation rate.[9,19] Intermittent stretching of isolated muscles increased protein synthesis and $PGF_{2\alpha}$.[21] Thus, incubated stretched muscles is another example of a condition in which muscle catabolism is reduced despite elevated levels of prostaglandins, further suggesting that PGE_2 is not an important mediator of accelerated muscle proteolysis.

Although the present results suggest that accelerated muscle proteolysis during sepsis is not induced by PGE_2, it should be emphasized that results were achieved in an experimental septic model using small rats and muscles incubated *in vitro.* The possible role of prostaglandins for increased muscle protein breakdown in septic patients remains to be determined. It should also be pointed out that protein degradation was measured as release of tyrosine from incubated muscles. Tyrosine release reflects total protein breakdown, and recent studies suggested that changes in myofibrillar protein breakdown, measured as release of 3-methylhistidine, can go undetected when tyrosine release is used to assess protein breakdown rate.[29] In future experiments, the effect of indomethacin on myofibrillar protein breakdown should be studied to further elucidate the role of prostaglandins for regulation of muscle protein breakdown during sepsis.

Long-term Follow-up of Patients with Biopsy-proven Benign Breast Disease

HANS-BEAT RIS, M.D., URSULA NIEDERER, M.D., HANS STIRNEMANN, M.D.,*
JAN EVA DORAN, PH.D.,† and ARTHUR ZIMMERMANN, M.D.‡

Three hundred sixty-five patients with biopsy-proven benign breast disease were followed annually in a prospective manner for 4–15 years to analyze breast cancer development, recurrence, and efficacy of management during follow-up. Eleven breast cancers developed in 11 patients during follow-up, giving a 2.6-fold increased cancer risk over the reference population. No association was found between patients who developed cancer and those who did not with respect to the initial histologic feature ($p = 0.62$), the age at entry by decades ($p = 0.40$), and relative to menopause ($p = 0.54$), the presence of cysts ($p = 0.87$), or calcification ($p = 0.74$) in the biopsy specimen, a family history of breast cancer ($p = 0.80$), or the number of observation years ($p = 0.27$). We conclude that an aggressive approach to benign breast disease is not justified for any type of lesion as defined in this report. Benign breast disease does not inevitably lead to recurrence. Moreover, 41% of our patients never had any recurrence and were free of symptoms during follow-up; 67% never had a mammogram and 82% never required a further operation. There was no association with initial histologic feature in patients who had clinical examination only and those who had mammogram, biopsy, or both during follow-up ($p = 0.93$). Mammograms were mainly used to clarify a clinical recurrence than as a screening tool, regardless of histologic feature ($p = 0.76$). Mammograms were mainly used in premenopausal patients ($p < 0.001$) having lumps ($p < 0.001$), namely, the most difficult patients for radiologic interpretation. This may be one important reason for the rather low sensitivity (75%) and specificity (40%) of mammography in this report. In conclusion, clinical examination is the outstanding investigational tool to follow patients with biopsy-proven benign breast disease, especially in young premenopausal patients.

From the Department of Surgery, Burgdorf-Hospital, Burgdorf, Switzerland, the Department of Experimental Surgery,† and the Department of Pathology,‡ University of Bern, Bern, Switzerland*

THE DIFFICULTY in understanding benign breast disease is reflected in the large spectrum of recommendations for its further management; benign breast disease remains a vexing clinical problem. While special concern always arises with its role in breast cancer development, little is known about recurrence and preferential pattern of management in practice of patients with benign breast disease. In this report the data of a prospective long-term follow-up of patients with biopsy-proven benign breast disease are analyzed with respect to cancer development and recurrence, as well as the pattern and efficacy of further management.

Materials and Methods

All women operated for benign breast disease in our clinic since January 1, 1970 are followed up annually in a prospective manner. Patients operated for the initial lesion between 1970 and 1981 inclusive are the subjects of this report. Each patient has been examined annually by the same two clinicians, followed by mammograms, biopsies, or both when deemed appropriate. In addition to these formal assessments, the patient may be referred by family doctors for mammograms, biopsies, or both because of breast problems. All investigations were taken into account in this study.

All slides of initial and subsequent lesions were reinterpreted and classified in a uniform manner by two pathologists by blind duplicate readings without the knowledge of subsequent breast cancer development (Table 1). Throughout this paper we use the term breast cancer to mean invasive breast cancer. A benign biopsy specimen is defined as one that contained neither invasive breast cancer nor a carcinoma in situ. Patients with a previous history of breast cancer were excluded from the study, but breast cancer development during follow-up was no reason for exclusion. Bilateral simultaneous biopsies are counted as one operation, the lesion with the more distinct alteration being considered for classifi-

TABLE 2. *Classification of Original Mammographic Test Results*

1	Definitely benign.
2	Probably benign (not optimal radiologic presentation); repeat mammogram indicated.
3	Probably malignant (one radiologic feature of malignancy); early repeat mammogram or biopsy indicated.
4	Definitely malignant; biopsy strongly advised.

cation. The initial lesion was bilateral in 36 patients. All biopsies were performed under supervision in a resident teaching program. Fine-needle aspiration cytology was not used. The originally reported interpretations of the mammograms performed during follow-up were classified according to their test result (Table 2).

The data were analyzed using the SPSS PC statistical package on an IBM-XT computer. Chi square contingency analyses, the Fisher's exact test, one-way ANOVA, and median tests were used where appropriate. Statistical significance was accepted at a $p < 0.05$.

Follow-up

Between 1970 and 1981 inclusive, 383 women (100%) were operated for benign breast disease and therefore qualified for the study. Eighteen patients were lost and 365 (95%) were followed up to 15 years with a total of 3145 observation years and a mean follow-up time of 8.6 years. Three hundred thirty-seven patients (88%) had a complete follow-up until 1985 with a minimal follow-up time of 4 years, while 28 patients had an incomplete one: two due to death from breast cancer, 11 due to death of unrelated causes, 12 due to departure, and three due to lack of cooperation.

Results

Pattern of Age at Entry, Initial Histologic Feature, and Family History of Breast Cancer

The distribution of the 365 patients according to the age at entry by decades and initial histologic feature is shown in Table 3. The mean age at entry of the 365 patients was 42.6 years. The follow-up periods for each decade did not differ markedly except for those patients older than 70 years of age where the follow-up time was somewhat shorter. In 65 patients, the initial lesion was proliferative without atypia and in 28 patients proliferative with atypia. The follow-up periods for the cohorts according to type of initial lesion did not differ markedly except for patients with fibrocystic disease without proliferation and for patients with regressive changes where the follow-up time was somewhat longer.

A disproportional distribution of the 365 patients appeared if type of initial lesion was matched by age at entry. The median age of patients with fibroadenoma, adenosis and fibrosis, lipomatosis and fibrosis, and fibrocystic disease without proliferation was less than 43 years, whereas for patients with proliferative disease without and with atypia and regressive changes the median age was more than 43 years ($p = 0.016$). The presence of cysts of 0.3 cm in diameter or more was noted in 73 and the presence of calcification in 66 initial biopsy specimens; 23 of the 365 women had a family history of breast cancer in a mother or sister.

Breast Cancer Development

Eleven invasive breast cancers subsequently developed in 11 of 365 patients during follow-up, the overall annual cancer incidence being 3.5 per 1000 observation years. Using the data of the tumor registration office in Basel, Switzerland (unpublished), we determined the number of cases of cancer that would have been expected to occur in our studied population according to our observation period and to the age-specific distribution of our population. The ratio of our observed incidence to the predicted number is used to define the relative risk of 2.6 according to Kodlin et al.[1] We com-

TABLE 3. *Distribution of the 365 Patients According to Age at Entry and Type of Initial Lesion with Mean Follow-up Times*

Age at Entry (yr)	No. of Patients	Average Follow-up Time (yr)	Type of Lesion	No. of Patients	Average Follow-up Time (yr)
10–19	13	8.7	1	117	9.7
20–29	51	8.7	2	65	8.8
30–39	86	8.3	3	28	8.1

TABLE 4. *Correlations with Breast Cancer Development*

	P Value
Age at entry by decades	0.39
Age at entry: premenopausal/perimenopausal/ postmenopausal*	0.54
Histologic type of initial lesion	0.62
Presence of calcification in the biopsy specimen	0.74
Presence of cysts in the biopsy specimen	0.87
Family history of breast cancer	0.80
No. of observation years (1–15 years)	0.27
No. of assessments	0.17
Presence of pain at assessment	0.28
Presence of lump at assessment	<0.001

* Premenopausal, <45 years; perimenopausal, 45–55 years; postmenopausal, >55 years.

pared the characteristics of those patients in our study who developed breast cancer during follow-up with those who did not (Table 4). When the patients are classified with respect to the age at entry by decades or relative to menopause, there was no significant difference between patients with cancer development and those without.

Furthermore, there was no significant association in the type of initial lesion in patients who developed cancer and those who did not. Patients with proliferative disease, with or without atypia, showed no significant difference in cancer incidence as compared to the rest of our study population. There was no correlation between cancer development and the presence of cysts or calcification in the initial biopsy specimen. In addition, there was no association between cancer development and a family history of breast cancer; moreover, not a single patient with cancer development during follow-up had a family history of breast cancer.

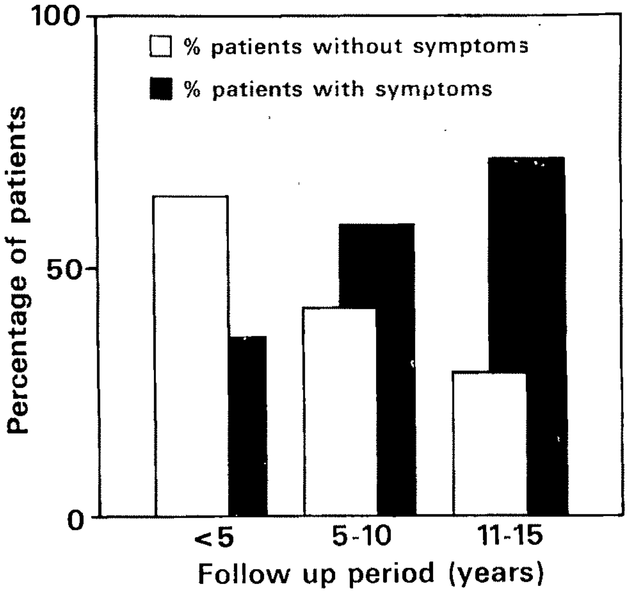

FIG. 1. Percentage distribution of patients with and without recurrence (pain and/or lump) at assessment, according to follow-up time (N = 365).

Patients with breast cancer development and those without had similar periods of follow-up. No association was found between presence of pain at control and breast cancer development, whereas the presence of lump at control was significantly associated with cancer development. All patients with cancer had a lump at control.

Recurrence

Lump and/or pain at assessment during follow-up was considered as recurrence. Figures 1 and 2 show the patterns of recurrence, cancer development, and performed investigations (mammograms and biopsies) during follow-up. The average age at entry was similar for each follow-up period related cohort ($p = 0.67$). With increasing follow-up time there was a significant increase of patients with recurrence ($p < 0.001$) and with subsequent investigations but no significant increase of patients with cancer development. However, of the 365 patients, 150 (41%) never had any recurrence at examination and were free of symptoms during follow-up, 300 (82%) never had a further operation, and 243 (67%) never had a mammogram.

Is recurrence confined to initial side and histologic feature? In 65 patients a reoperation was performed to clarify a recurrence during follow-up. There was no significant association between the side of reoperation and the side of the initial lesion ($p = 0.13$). However, there was an association between type of initial and subsequent lesion. In a significant number of patients the subsequent histologic feature was the same as the initial one ($p < 0.001$).

Is the clinical feature of the recurrence related to type of initial lesion or age at entry? Patients with a lump at assessment were younger (premenopausal) at entry than those without ($p < 0.001$). More patients with fibrocystic disease or proliferative disease without atypical hyperplasia as initial lesions had pain at assessment than would have been expected ($p < 0.001$). There was no association between lump at assessment and initial histologic feature ($p = 0.79$) and no association between pain at assessment and age at entry ($p = 0.15$).

Pattern of Management

Table 5 shows the distribution of the 365 patients according to type of initial lesion and subsequent management during follow-up. There was no significant association with initial histologic feature in patients who had clinical examination only during follow-up and those who had mammogram or biopsy or both during follow-up (p = 0.93).

Clinical examination. Two hundred twenty-three patients (61%) had regular clinical examinations only, at formal assessment and by family doctors, without mammogram or biopsy. A total of 11 breast cancers developed during follow-up in the 365 patients. Eight of them were detected by clinical examination only and three were predicted by mammograms. There was no difference in tumor size and lymph node involvement between the cancers detected by clinical examination only and those predicted by mammograms.

Mammogram. One hundred twenty-two patients (33%) had a total of 180 mammograms during follow-up; 19 mammograms were followed within 3 months by a biopsy and were used to determine specificity (40%) and sensitivity (75%) of mammography because of confirmed disease status. There was no significant difference between patients who had mammograms during follow-up and those who had not according to initial (p = 0.71) and subsequent (p = 0.52) histologic feature, number of controls (p = 0.30), and presence of pain at control (p = 0.07). A significant difference was found, however, according to age at entry and presence of lumps at control. Patients with mammograms were younger (less than 45 years) at entry (p = 0.001) and had more lumps at control (p < 0.001) than those without mammograms.

Biopsy. Sixty-five patients (18%) had one or more, ten had two or more, and three had three reoperations during follow-up. The more reoperations performed, the higher the ratio of detected cancers, 11% at the first, 20% at the second, and 67% at the third reoperation.

Discussion

Our patients with biopsy-proven benign breast disease had a 2.6-fold increased risk of breast cancer development as compared to the reference population, taking the age-specific distribution and period of follow-up into account. There is good agreement that patients with biopsy-proven benign breast disease are at increased cancer risk; estimates of the relative risk, however, have ranged from 1.4 to 4.8.[1-6] It is difficult to compare the different studies of benign breast disease, especially if the general population is used as a reference. The incidence of benign breast disease in the general population is not known,[7] and reliable information concerning other important breast cancer risk factors is absent. The slightly increased cancer risk in women with biopsy-proven benign breast disease may be the result of a disproportionate distribution of such factors rather than the result of benign breast disease *per se.* Therefore, we compared those patients in our study who developed breast cancer during long-term follow-up with those who did not. In contrast to other reports,[1-3,8] we found no association between type of initial histologic feature and cancer development; patients with atypical hyperplasia did not

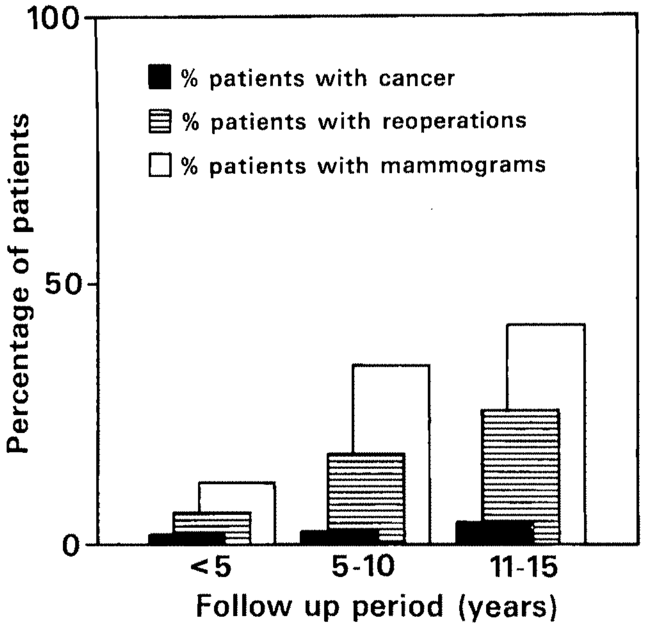

FIG. 2. Percentage distribution of patients with breast cancer development, mammograms, and reoperations, according to follow-up time.

TABLE 5. *Distribution of the 365 Patients According to initial Histologic Feature and Subsequent Management During Follow-up (Clinical Examination Only, Clinical Examination with Mammogram or Biopsy, or Both)*

7	10	(63)	2	(13)	3	(19)	1	(6)	16	(100)

develop more cancers than patients with other histologic features. Caution in the interpretation of the data is indicated because of the limited number of patients with atypical hyperplasia in our study. However, it was pointed out that most of the histologic features do not place the patients at a markedly increased cancer risk, except the very small number of lesions similar to or consistent with carcinoma in situ.[2] Patients with carcinoma in situ as initial lesion were excluded from this study, and carcinoma in situ was not observed as recurrent lesion during follow-up.

Another surprising finding was the lack of association between age at entry and subsequent cancer development. Older patients at entry did not develop more cancers during follow-up than younger patients. Previous reports have shown similar correlations,[2] but caution in the interpretation is indicated because of the somewhat shorter follow-up of patients older than 70 years of age. There was no association between cancer development and the presence of cysts or calcification in the initial biopsy specimen. Patients with a family history of breast cancer did not develop more breast cancers during follow-up than those without. Dupont and Page[2] demonstrated that the presence of cysts or calcification or a family history of breast cancer alone had little effect on cancer development; patients with calcification in the biopsy specimen and a family history of breast cancer had a marked increased cancer risk only in conjunction with the rare lesions similar or consistent with carcinoma in situ. Patients with cysts and a family history of breast cancer were at increased cancer risk in their report,[2] but the two groups were not stratified according to histologic feature.

Biopsy-proven benign breast disease does not inevitably lead to recurrence with increasing follow-up time. Of the 365 patients with a follow-up time up to 15 years, 41% never had any recurrence at assessment and were free of symptoms, 67% never had a mammogram, and 82% never had a further operation. With increasing time of follow-up there was no increase in developing cancer, although there was an increase in recurrences (defined as pain or lump) and subsequent investigations. Patients counted as having recurrence during follow-up may have had these symptoms only once and may have been subsequently free of symptoms for the rest of the observation time. Thus, the recurrence rate may actually be overestimated in this report.

If a reoperation was necessary to clarify the recurrence, there was no association between the side of initial and recurrent lesion, but in a significant number of patients the subsequent histologic feature was the same as the initial one. About 60% of all patients followed for a period up to 15 years had clinical examination only, at formal assessment and by family doctors, without mammograms and/or biopsies; 33% of all patients had one or more mammograms in addition to clinical examination, and 18% one or more biopsies. There was no association with initial histologic feature in patients who had clinical examination only and those who had mammogram or biopsy or both during follow-up. The majority of cancers were detected by clinical examination only, and no difference was found in tumor size and lymph node involvement between the cancers detected by clinical examination only and those predicted by mammograms. These findings suggest that regardless of initial histologic feature, most patients were followed routinely by clinical examination only in daily practice in our district. Mammograms or biopsies were rather used to clarify a distinct recurrence than as a screening tool despite the clear recommendation to perform mammograms in patients with proliferative disease at annual intervals during follow-up.[8,9] The specificity of mammograms with confirmed disease status was 40% and the sensitivity 75%. The efficacy of mammography must be rated higher because mammograms with negative test results impeded biopsies in patients with recurrence but without cancer development during follow-up. However, in numerous studies sensitivity has ranged from 31% to 91% and specificity from 51% to 98%.[10-20] It was pointed out that the clinical and radiologic heterogeneity of the female breast is an important source of this wide range in reported efficacy of mammography. Breasts of premenopausal women and those with fibrocystic disease are more difficult to interpret roentgenographically than breasts of older subjects and those without fibrocystic disease.[10] The patients in our study having mammograms during follow-up were younger and had more lumps than patients without mammograms. Thus, in our study mammograms were used in the most difficult patient group for radiologic interpretation. This may well adversely influence the accuracy of mammography and may challenge this method as the method of choice to clarify recurrence in young patients with benign breast disease.

We conclude that an aggressive approach to biopsy-proven benign breast disease is not justified for any type of benign lesion as defined in this report. Clinical examination is the outstanding investigational tool to follow patients with biopsy-proven benign breast disease. The status of mammography in the follow-up of patients with benign breast disease is open to question, especially in young premenopausal patients.

Further Evidence Supporting a Cause and Effect Relationship Between Blood Transfusion and Earlier Cancer Recurrence

NEIL BLUMBERG, M.D., JOANNA HEAL, M.B.B.S., M.R.C.P.,* CHRISTY CHUANG, PH.D.,†
PAUL MURPHY, M.D., and MUKESH AGARWAL, M.D.

Studies of associations between perioperative blood transfusions and later recurrence of solid tumors have yielded conflicting results. A previous analysis of transfused patients suggested that recurrence was associated with transfusion of whole blood as opposed to red blood cell concentrates. Additional analyses were performed on patients with cancers of the colon, rectum, cervix, and prostate to determine if patients receiving whole blood, red blood cells only, or no transfusions had differing outcomes. Patients receiving 1 unit or more of whole blood had uniformly poor outcomes compared with nontransfused patients ($p < 0.001$). In contrast, patients receiving only red blood cells had progressively worse recurrence and death rates with increasing numbers of transfusions, suggesting the presence of a dose-effect relationship. Employing multivariate techniques, blood transfusions of ≤3 units that included any whole blood were independently and significantly associated with earlier recurrence ($p = 0.003$) and death due to cancer ($p = 0.02$). Transfusions of ≤3 units of blood comprised solely of red blood cell concentrates were associated with no greater risk of recurrence than that seen in patients receiving no transfusions ($p = 0.50$). These results provide a potential explanation for the disparate results reported in studies of blood transfusion and cancer outcome. The marked difference in outcome seen between patients receiving a few units of red blood cells and comparable patients receiving even one unit of whole blood are consistent with the hypothesis that transfusion of stored blood plasma causes earlier tumor recurrence in some instances. Strategies for reducing these risks might include avoidance of whole blood transfusions when only 1–3 units are required, more conservative transfusion practice, use of autologous blood transfusions, and perhaps, use of red blood cells washed free of plasma and white cell debris. Clinical trials to test these hypotheses are urgently needed.

From the Blood Bank, Department of Pathology and Laboratory Medicine, and the Hematology Unit of the Department of Internal Medicine, the University of Rochester Medical Center, American Red Cross Blood Services, Rochester Region, Rochester, New York; and the Upjohn Co, Kalamazoo, Michigan†*

SINCE THE FIRST REPORT by Burrows and Tartter[1] numerous studies have appeared demonstrating a relationship between perioperative blood transfusions and later recurrence of solid tumors, including cancers of the colon and rectum,[2-6] lung,[7,8] breast,[9,10] kidney,[11,12] vulva,[13] cervix,[14] stomach,[15] and soft-tissue sarcomas.[16] An almost equal number of studies have found smaller or no differences between transfused and nontransfused patients.[17-26]

We recently reported that in patients with colorectal, cervical, or prostate cancers transfused with whole blood there was an independent association between transfusion and poorer clinical outcome.[27] Patients receiving small numbers (≤3) of red blood cell concentrates had fewer and later recurrences than patients receiving equivalent numbers of blood transfusions that included even 1 unit of whole blood. Patients receiving four or more red blood cell transfusions had recurrence and survival experiences similar to those of patients receiving whole blood transfusions. These differences could not be readily explained in terms of other prognostic factors such as age, type of tumor, clinical or histologic stage, preoperative anemia, length of follow-up, or duration of surgery (this last factor being employed as a surrogate measure of surgical difficulty).

These results led us to hypothesize that previous studies failing to find associations between blood transfusions and cancer recurrence might be explained in part by differing patterns of blood component usage. That is, if only red cell concentrates were transfused, and in small numbers, no or smaller differences in recurrence rates between transfused and nontransfused patients might be expected. We report here additional analyses of our previously reported patients intended to test this hypothesis. Comparison is made between the outcome

Submitted for publication: November 17, 1987.

in patients receiving no transfusions and that in patients receiving either small numbers of red blood cell concentrates only, or small numbers of transfusions that included at least 1 unit of whole blood. We also present data suggesting a dose-effect relationship between number of red cell transfusions and the likelihood of tumor recurrence.

Patients and Methods

The 216 transfused patients with cancer of the colon, rectum, cervix, or prostate have been previously reported as part of a comparison of cancer recurrence and death after whole blood or red cell transfusions.[27] Data on the nontransfused patients reported here for the first time were collected simultaneously as part of the same retrospective medical record review. Details of both clinical and statistical methods are identical for both this report and the previous study comparing red cell and whole blood recipients.[27] In brief, the names and identifying numbers of hospital patients seen between 1970 and 1982 with these diagnoses were retrieved from a computerized data base and the medical record reviewed, collecting a variety of demographic, clinical, and treatment data. Transfusion data were also confirmed from blood bank records. Patients were included in the study if they had undergone surgery at our institution, documented follow-up of at least 6 months was available, no evidence existed of metastatic disease at diagnosis, and the transfusion history and diagnosis of cancer were unambiguous. We designated patients as transfused if the transfusions occurred within a 1-month span before or after surgery. The vast majority of transfusions occurred immediately preoperatively, intraoperatively, or within a few days postoperatively. Patients receiving transfusions at other times are not included in this analysis. Individual multivariate analyses for each tumor, including proportional hazards risk models, have been published for the colon and rectal cancer data,[2,3] described in abstract for the cervical cancer data,[14] and are in press for the prostate cancer data. The results for each tumor analyzed separately suggested that transfusion is significantly associated with cancer recurrence and/or death due to the tumor, even after adjustment for clinical stage, anemia at diagnosis, duration of surgery, patient age, *etc.*

All transfused patients received either red blood cells, whole blood, or some combination of these components. A very small number of patients received fresh frozen plasma (13 of 216) or platelet concentrate transfusions (1 of 216). As initial analysis of the data suggested that recurrence was associated with transfusion of whole blood, we grouped the patients into those who had received only red cells and those receiving at least 1 unit of whole blood. Patients who received only red cells and fresh frozen plasma and/or platelets but no whole blood were grouped with the patients receiving whole blood.

A total of 216 transfused patients are analyzed of whom 120 had colon or rectal cancer, 62 had cervical cancer, and 34 had prostate cancer. The 354 nontransfused patients comprised 68 with colon or rectal cancer, 61 with cervical cancer, and 225 with prostate cancer. The numbers of recurrences and cancer related deaths for the colon/rectal, cervical and prostate groups were, respectively, (54; 20), (16; 8), and (19; 6) for the transfused patients and (6; 3), (18; 5), and (69; 21) for the nontransfused patients. The proportion of transfused patients having recurrences or death due to cancer was significantly higher than in the nontransfused patients for the colon/rectal and prostate cancer patients but not for those with cervical cancer. The trends for recurrence and death reported by kind and amount of blood transfused were similar for each tumor. A breakdown of the data by tumor is available from the authors.

Statistical Analysis

The methods detailed in our previous reports were employed.[3,27–31] The prognostic factors in our analyses included age, year of surgery, duration of surgery, admission hematocrit, kind and amount of blood components received, type of cancer, and stage of cancer. In order to analyze this last factor for patients with different types of cancer, an improvised classification was devised for statistical analysis purposes. Early stage included patients with cervical cancers of clinical Stages O and IA, colon and rectal cancers of histologic Stage A, and prostate cancers of clinical Stages A_1 and A_2. Intermediate stage included patients with cervical cancer Stages of IB, IIA, and IIB, colon, rectal, and prostate cancer Stages B_1 and B_2. Advanced stage included patients with cervical cancer Stages IIIA and IIIB, colon and rectal cancer Stages C_1 and C_2, and prostate cancer Stage C. We appreciated that this process would not yield precise data on the effect of Stage upon cancer recurrence, but wished to incorporate broadly representative information on stage in our study of prognostic factors that might be associated with transfusion and cancer recurrence.

When fitting proportional hazards models to time to recurrence and survival time, we first included as predictors all the previously noted prognostic factors, but not the type of blood component transfused.[30] The nonsignificant factors were excluded, and type of blood transfused (none, whole blood, red cells) was then added to the proportional hazards model to see if the change in the log-likelihood after adding transfusion status was

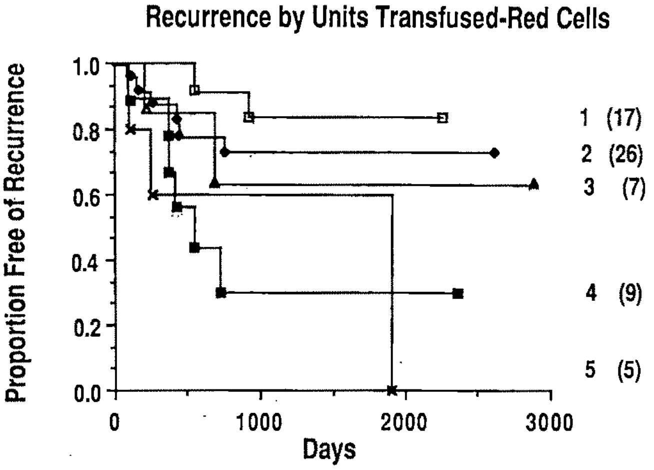

FIG. 1. The Kaplan-Meier plots for the estimated time to recurrence for patients receiving only red blood cell concentrates are shown. The numbers to the right of each line represent the number of units of red blood cells received by the patients in that group. The numbers in parentheses are the number of patients in that group. Six patients received more than five red blood cell units and had similar recurrence-free survivals to those receiving 4 or 5 units of red blood cells. These data are not shown. Because of the small number of patients in each group, data were pooled for statistical analysis. Patients receiving 1 or 2 units of red blood cells had significantly lower recurrence rates than those receiving 3 or 4 units (p = 0.02 by Breslow, 0.01 by Mantel-Cox). Patients receiving 2 or 3 units of red blood cells had significantly lower recurrence rates than those receiving 4 or 5 units (p = 0.06, 0.03). Patients receiving 3 or 4 units of red blood cells had similar recurrence estimates to those receiving 5 or more units (p = 0.98, 0.95).

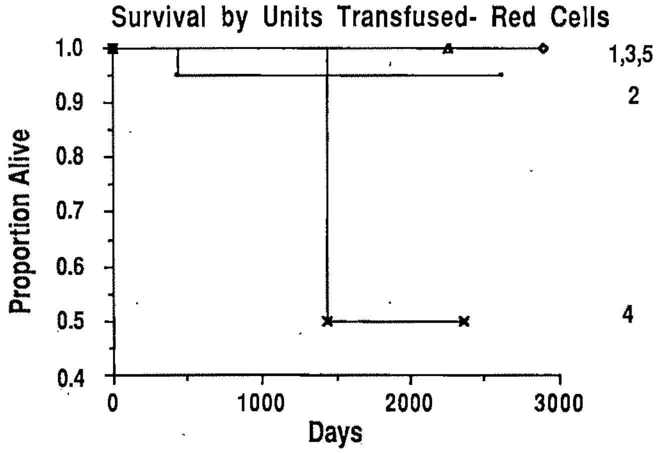

FIG. 3. The Kaplan-Meier plots for the estimated survival time for patients receiving only red blood cell concentrates are shown. The numbers to the right of each line represent the number of units of red blood cells received by the patients in that group. The numbers of patients in each group are identical to those in Figure 1. These curves are not significantly different from each other since there were only four deaths in these groups. However, when the six patients receiving >5 units of red blood cells are included in the analysis and data are pooled, patients receiving 1 or 2 units of red cells had significantly longer estimated survival times than those receiving 5 or more red blood cell transfusions (p = 0.03, 0.01).

significant. By entering information on transfusion last we could measure the impact of type of blood component transfused on time to recurrence and survival time after adjustment for other factors. We thus obtained an estimate of the effect on recurrence and death attributable to type of blood transfusion.

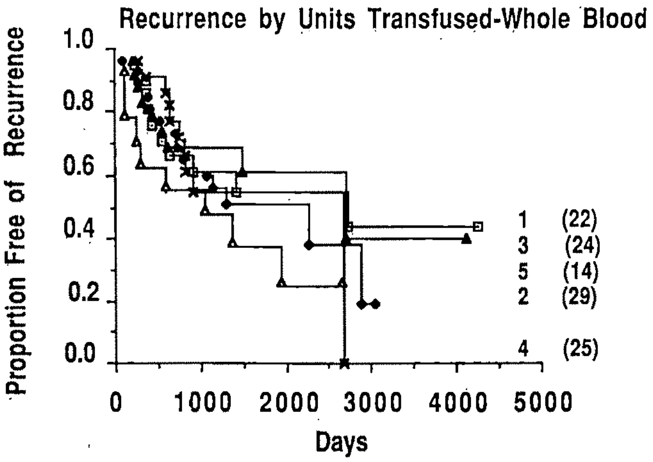

FIG. 2. The Kaplan-Meier plots for the estimated time to recurrence for patients receiving at least 1 unit of whole blood are shown. The numbers to the right of each line represent the total number of units of whole blood and red blood cells received by the patients in that group. The numbers in parentheses are the number of patients in that group. Thirty-two patients received a total of more than 5 whole blood and red blood cell units and had similar recurrence-free survivals to those receiving 1–5 units of whole blood and red cells. These latter data are not shown. None of the differences between these curves achieved statistical significance by the Breslow or Mantel-Cox tests (p = 0.46, 0.48 for the comparison of all the plots taken together).

Kaplan-Meier's product-limit method was used to estimate the unadjusted distributions of time to recurrence and survival time.[31]

Results

In our initial study of the transfused patients, earlier recurrence and death due to cancer was associated most strongly with any transfusion that included at least 1 unit of whole blood, and with transfusion of ≥4 units of red blood cells.[27] Therefore, we initially analyzed the unadjusted time to recurrence and survival time according to number of units of blood transfused by the Kaplan-Meier method. Estimates of the recurrence-free interval and survival time for patients receiving different amounts of whole blood or red blood cells are shown in Figures 1–4. The plots for the whole blood recipients are not statistically significantly different from each other (Figs. 2 and 4). The recurrence plots for the patients receiving only red blood cell transfusions are significantly different and suggest a dose-effect relationship (Fig. 1). That is, increasing numbers of transfusions appear to be associated with proportionally greater numbers of earlier recurrences. Because of the small number of deaths in the patients receiving only red blood cells, no assessment of a dose-effect relationship between number of transfusions and earlier death can be made in this group (Fig. 3).

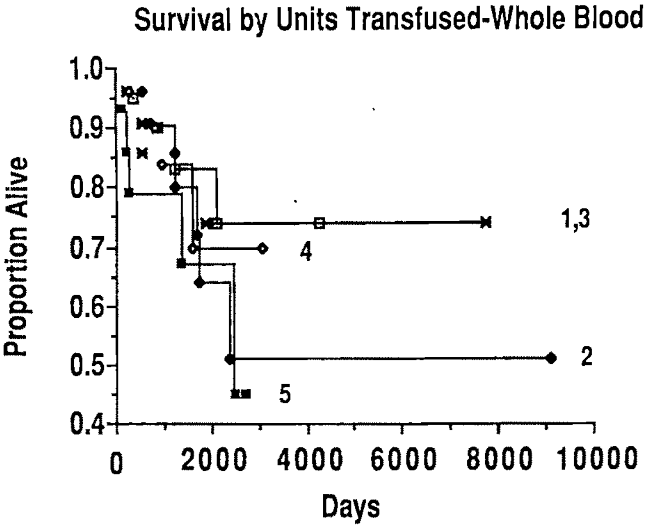

FIG. 4. The Kaplan-Meier plots for the estimated survival time for patients receiving at least 1 unit of whole blood are shown. The numbers to the right of each line represent the total number of units of whole blood and red blood cells received by each of the patients in that group. The numbers of patients in each group are identical to those in Figure 2. These plots are not statistically significantly different from each other (p = 0.52, 0.63). Addition of the patients receiving more than five transfusions and pooling of data do not alter the results of the analysis.

To assess the differences in recurrence and survival between patients transfused with comparable, small numbers of whole bloods or red blood cells, and those who were not transfused at all, we performed further Kaplan-Meier analyses on patients receiving no blood or no more than 3 units of blood. We limited this particular analysis to patients with mild to moderate blood loss in order to avoid including patients with particularly difficult resections or massive hemorrhages.

We further performed on this subset of our patients a multivariate proportional hazards risk analysis (Cox regression) of the factors predicting recurrence and death due to cancer, including patient age, year of surgery, duration of surgery, hematocrit on admission, type of cancer, histologic or clinical stage of cancer, and kind of blood component received. Because such a small proportion of the prostate cancer patients were transfused (13%) as compared with patients with colorectal (64%) or cervical (50%) cancer, the comparisons of pooled data between transfused and nontransfused patients were restricted to patients with colon, rectal, and cervical cancers. Only five patients with prostate cancer received red cells exclusively, an inadequate number for comparing the patients in this group with the 225 nontransfused patients. The 29 patients with prostate cancer who received whole blood transfusions or ≥4 units of red blood cells had significantly shorter recurrence-free intervals and survival times than the 225 nontransfused patients (data not shown).

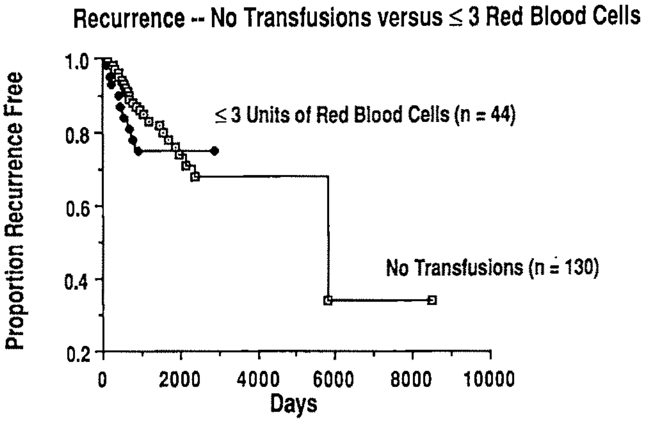

FIG. 5. The Kaplan-Meier plots for the estimated time to recurrence are compared for patients with cervical and colorectal cancers receiving ≤3 units of red blood cells and for patients receiving no transfusions (the prostate cancer patients are not included in these data as only five patients received ≤3 units of red blood cells). These curves are not significantly different from each other (p = 0.15, 0.31). The plots for estimated survival time are similar to these shown for recurrence and not significantly different (data not shown) (p = 0.97, 0.83).

Figure 5 displays a comparison of the unadjusted estimated time to recurrence in colorectal and cervical cancer patients who received ≤3 units of red blood cells and those patients with these cancers who received no blood transfusions. The differences are not significant (p = 0.15; 0.31). The results for comparisons of the estimated time to death due to cancer were similarly not significantly different (data not shown, p = 0.97; 0.83). Figure 6 shows a similar comparison for patients receiving ≤3 units of blood including at least 1 unit of whole blood and for the same group of patients shown in Figure 5 who were not transfused. The results in these two groups are significantly different (p = 0.0009; 0.002).

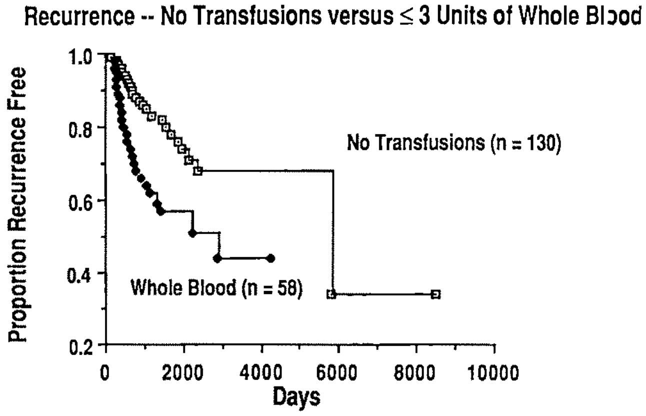

FIG. 6. The Kaplan-Meier plots for the estimated time to recurrence are compared for patients with cervical and colorectal cancers receiving a total of ≤3 units of blood including at least 1 unit of whole blood, and for patients receiving no transfusions (the prostate cancer patients are not included in these data). These curves are significantly different from each other (p = 0.0009, 0.002). The plots for estimated survival time are similar to these shown for recurrence and are significantly different (data not shown) (p = 0.0004, 0.0002).

Virtually identical results were obtained when survival times were estimated ($p < 0.001$; data not shown).

The factors that were significantly associated at the $p < 0.05$ level with earlier recurrence in the initial Cox regression analysis of patients receiving ≤3 units of red blood cells or no transfusions were older age, cervical cancer, and surgical duration of 2–3 hours. When transfusion type (*i.e.*, no transfusions vs. ≤3 units of red blood cells) was added back to this model, no statistically significant increase in the log-likelihood of recurrence or death was found after adjustment for the aforementioned prognostic variables ($p = 0.50$). Thus, transfusion status was not a significant independent predictor of time to recurrence in patients receiving only red blood cells in amounts ≤3 units or no transfusions. A Cox regression to determine which of the prognostic factors were significantly associated with shorter survival times demonstrated that only year of initial diagnosis was a significant predictor of survival time. Diagnosis prior to 1975 was significantly associated with death due to cancer. When transfusion status was added back to the model the contribution of this variable to prediction of cancer-related death was not significant ($p = 0.65$).

A similar Cox regression analysis was performed including patients receiving ≤3 units of whole blood and the aforementioned group of nontransfused patients. The significant predictors of earlier recurrence included low admission hematocrit (<38), more advanced clinical or histologic stage (intermediate and advanced stages), and surgery duration of 2–3 hours. After transfusion type was added back to this model, whole blood transfusion was an independent and significant predictor of earlier recurrence ($p = 0.003$). Low admission hematocrit, more advanced stage, and surgery duration of 2–3 hours were also associated with earlier death due to cancer in this group of patients (those receiving no transfusions or ≤3 units of whole blood). When the variable representing transfusion type (whole blood *vs.* no transfusions) was added to the regression model for survival time, whole blood transfusion was significantly and independently associated with shorter survival times ($p = 0.02$).

Discussion

These data further characterize the previously reported relationship between the kind and amount of blood transfused perioperatively, and the likelihood of later recurrence of, or death due to cancer. Our retrospective methodology and pooling of data from patients with widely differing tumors creates a risk of confounding factors distorting the analysis. Therefore, it is striking that a clear-cut pattern is evident. Patients with cervical or colorectal cancers receiving even 1 whole blood transfusion appear at markedly higher risk of tumor recurrence than patients receiving either ≤3 units of red blood cells or no transfusions at all. This risk is independent of other prognostic factors such as clinical or histologic stage, patient age, anemia, duration of surgery, and year of surgery. In contrast, patients receiving small numbers of transfusions limited to red blood cells did not have significantly worse recurrence or survival experiences than those receiving no transfusions, even when adjusted for other prognostic variables.

These results provide a likely explanation for the conflicting results seen in other retrospective studies of cancer recurrence and blood transfusion.[1-26] Transfusion practices vary greatly among medical centers. Our findings suggest that such variation could dramatically affect the results of analyses that do not take into account the kind of blood component transfused, as well as the number of units of blood transfused.

Employing surrogate markers for surgical complexity (duration of surgery) and tumor invasiveness (clinical and histologic staging), we find no evidence to support the hypothesis that transfusion status is acting as a marker for the tumor's aggressiveness or the clinical state of the patient. In fact, transfused patients with cervical or prostate cancer had somewhat more favorable clinical stage disease, on average, than patients who were not transfused. The best predictors of transfusion are preoperative anemia and lengthier surgeries. Even when these two factors predicting transfusion are adjusted for, transfusion of whole blood is a significant independent predictor of tumor recurrence and death due to cancer. If transfusion status were indeed only a surrogate indicator of tumor invasiveness or a patient's overall clinical condition, it is extremely improbable that this property would be evidenced to such different degrees in recipients of whole blood as opposed to those receiving red cell concentrate transfusions. The most likely explanation for the dramatic differences in outcome between those receiving no transfusions or ≤3 units of red cells and those receiving whole blood is that something present in whole blood modifies the mechanisms that prevent tumor recurrence.

Blood transfusion with plasma-rich components such as whole blood appears to increase the risk of solid tumor recurrence. An immunologic mechanism is most probably at work.[32] As such, transfusions of whole blood, plasma or its components, or large numbers of red cell concentrates should be avoided except when absolutely essential for patient well-being. These points previously have been made by others.[33,34] Obviously, these findings do not in any way argue against the appropriate treatment of significant hemorrhage with the indicated blood components. Severe hemorrhage presents an immediate and clear-cut threat to the patient whereas the risks we have described are long-term and still hypothetical.

Autologous predeposit transfusions also have much to recommend them in the clinical settings we describe. These include a decreased risk of post-transfusion viral infection.[35] There is no evidence that autologous transfusions would ameliorate the deleterious effects of blood transfusion we have proposed. However, if the effect of blood transfusion on outcome after cancer surgery is mediated by exposure to allogeneic antigens in transfused blood, it is reasonable to hope that such effects might be reduced or abrogated by the use of autologous blood transfusions. Given the other compelling reasons for use of autologous blood, its use in perioperative elective transfusions of cancer patients would seem a reasonable strategy, when feasible.

It also appears likely that use of red blood cells washed free of plasma, anticoagulant-preservative solutions, white cell, and platelet debris would mitigate to some degree the postulated effects of transfusion on tumor recurrence, but this remains to be proven in prospective, controlled interventional investigations.

The Effects of Hespan on Serum and Lymphatic Albumin, Globulin, and Coagulant Protein

CHARLES E. LUCAS, M.D., F.A.C.S., RONALD DENIS, M.D., ANNA M. LEDGERWOOD, M.D., F.A.C.S., and DENNIE GRABOW, B.S.

From the Department of Surgery, Wayne State University, Detroit, Michigan

The effects of hydroxyethyl starch (Hespan) resuscitation on serum and lymphatic proteins following hemorrhagic shock were studied in 34 splenectomized dogs. Following shock, five randomly assigned treatment groups received the shed blood plus 50 mL/kg of salt solution (RL) or RL with varying concentrations (0.22–1.5 gm/kg) of Hespan. Each dog received 50 ml/kg/d of the test solution for three days after shock. Prothrombin time, partial thromboplastin time, thrombin time, total serum protein, albumin, globulin, and coagulant protein activity of fibrinogen, prothrombin, and factor VIII were measured before shock, at the end of shock, following resuscitation, and on day 3; thoracic duct lymph values were obtained on day 3. Hespan-supplemented resuscitation lowered all serum proteins including albumin, globulin and coagulant proteins; concomitantly, the lymph protein rose after Hespan resuscitation. This decrease in serum proteins and rise in lymph proteins parallels similar results after albumin resuscitation in man and animals and suggests that Hespan induces an oncotically controlled extravascular protein relocation. Further studies on the significance of these findings need to be conducted.

RESUSCITATION from severe hemorrhagic shock is associated with a reduction in total serum protein (TSP) and serum albumin (SA) concentrations plus a marked rise in obligatory extravascular water sequestration, primarily in the interstitial fluid space.[1,2] Increased capillary permeability after the shock insult is purported to augment this extravascular expansion. Although supplemental albumin therapy has been proposed to counter this capillary leak syndrome,[3] controlled clinical and canine studies show that albumin supplementation induces extravascular protein relocation of all nonalbumin proteins including the globulins, the immunoglobulins, and the coagulant proteins.[4–6] Hespan, a hetastarch with an average molecular weight of 450,000, has been proposed as a more suitable plasma expander.[7,8] Hespan is derived from a waxy starch composed mainly of amylopectin with hydroxyethyl ether introduced into some of the glucose units so that the final product has seven substituted radicals per every ten remaining glucose groups. The end product is stable with a long shelf-life and an intravascular half-life long enough to maintain a colloidal effect for 24–36 hours after infusion. A 6% Hespan solution has colloidal properties similar to albumin. Hespan is slowly metabolized so that about 1% remains in the body after 2 weeks. The usual dose is 30–60 g/d in the averaged size adult. Little data are available on the effects of Hespan on serum protein concentrations and serum protein activity. The present study was designed to determine the effects of Hespan-supplemented resuscitation on serum and lymphatic albumin, globulin, and coagulant proteins.

Materials and Methods

Hespan was studied in 40 male conditioned dogs with an average weight of 22 kg (range: 18–26 kg). Eleven days prior to hemorrhagic shock, splenectomy was performed under general anesthesia using thiamylal sodium injection (11–17.5 mg/kg) and atrophine (0.05 mg/kg) for induction followed by methoxyflurane for light maintenance. Prior to anesthesia baseline measurements were obtained. Following full recovery 11 days later, the animals were again anesthetized. Using sterile technique the femoral artery and vein were cannulated to permit arterial hemorrhage, intermittent blood sampling, and volume restoration as defined by the protocol. A pulmonary artery catheter was positioned through the external jugular vein. Systemic and pulmonary vascular pressures were monitored continuously

on a previously balanced and calibrated two-channel recorder. The electrocardiogram was continuously monitored.

A modified Wigger's reservior hemorrhagic shock model was used.[6] Following preshock baseline hemodynamic and blood studies, the animals were rapidly bled into a preheparinized (100 units/kg) reservoir to a mean arterial pressure (MAP) of 60 torr and maintained at this level for 90 minutes by appropriate withdrawal or reinfusion of blood. The animals were then rapidly bled to a MAP of 40 torr and maintained at this level for 30 minutes when repeat hemodynamic and blood measurements were made.

After the shock insult, the animals were randomly allocated to five resuscitation groups. The sequence of resuscitation was designed to mimic the clinical setting with each animal receiving 20 mL/kg body weight test solution, the shed blood from the reservoir, and then 30 mL/kg test solution. The test solutions included: (1) lactated Ringers solution (RL); (2) RL with 0.22 g/kg body weight Hespan (RL/H22); (3) RL with 0.45 g/kg Hespan (RL/H45); (4) RL with 0.9 g/kg Hespan (RL/H90); and (5) RL with 1.5 g/kg Hespan (RL/H150). When the last of the test infusion was infused, post resuscitation hemodynamic and serum measurements were repeated. The lines were removed and the animals were returned to their cages and allowed diet as tolerated. Additional test solution (50 mL/kg) was infused daily until the animals were restudied on day 3. The day 3 studies were done with general anesthesia. Besides replacing previous lines, thoracic duct cannulation was added to measure lymphatic flow rates and protein levels. The animals were then killed by the intracardiac injection of potassium chloride and bilateral pneumothoraxes. The hemodynamic and serum parameters measured preshock, after shock, following resuscitation, and on day 3 included systolic, diastolic and MAP, cardiac output, systemic vascular resistence (SVR), and central filling pressure, (PCWP), TSP,[9] SA,[9] ${}_{\text{alpha1}}$-globulin (${}_{\alpha1}$G),[9] ${}_{\text{alpha2}}$-globulin (${}_{\alpha2}$G), betaglobulin (βG), gamma globulin (γG), fibrinogen activity (Ic),[10] prothrombin activity (IIc),[11] coagulant factor VIII activity (VIIIc),[12] plasminogen activity (Pg),[13] antithrombin III activity (ATIIIc).[14] Prothrombin time (PT),[15] activated partial thromboplastin time (PTT),[12] and thrombin time (TT)[16]; thoracic duct protein levels were measured on day 3. Statistical comparisons of the four Hespan supplemented groups to the control RL group were made by multiple ANOVA and Student's t-test where appropriate. Significance was inferred when the level of confidence exceeded 95%.

Results

The shock insult produced similar hemodynamic changes and similar protein changes in all five groups. These changes were almost identical to prior studies with this model.[6]

Following randomization and initiation of resuscitation, six dogs died (none in RL group, one in RL/H22 group, two in RL/H45 group, one in RL/H90 group, and two in RL/H150 group) so that only 34 animals were included in the final statistical analysis. All five resuscitation regimens restored vital signs and peripheral perfusion to predefined resuscitation end points that were not significantly different for each group.

The resuscitation regimen, however, did significantly affect serum protein concentrations. The post resuscitation TSP, SA, and SG levels in RL group averaged 6.5 g/dL, 2.8 g/dL, and 3.7 g/dL, respectively. In contrast, the post resuscitation TSP, SA, and SG levels were significantly lower in all four Hespan groups with the lowest values being 3.3 g/dL, 1.5 g/dL, and 1.6 g/dL, respectively (Table 1). The serum ${}_{\alpha1}$G, ${}_{\alpha2}$G, and the βG fractions were significantly reduced after hespan resuscitation (Table 1). These reductions in serum protein levels remained depressed through the day 3 study in those animals receiving Hespan supplementation (Table 1). Only the βG fraction remained undepressed in the Hespan groups when compared to the RL group. The lymphatic concentrations of proteins rose after Hespan-supplemented resuscitation. The average concentrations of lymphatic total protein (LTP), LA, and LG on day 3 were 2.7 g/dL, 1.3 g/dL, and 1.49 g/dL in the RL group. In contrast, these lymphatic proteins rose after Hespan resuscitation with the highest LTP, LA, and LG on day 3, averaging 4.1 g/dL, 2.0 g/dL, and 2.1 g/dL, respectively (Table 2).

Serum coagulant protein levels paralleled the other serum proteins. The preshock and post shock coagulant protein activity of Ic, IIc, VIIIc, ATIIIc, and Pg were similar in all five groups and were similar to prior studies with this model.[6] The activities of most coagulant proteins were reduced after Hespan resuscitation when compared to the RL group (Table 3). This reduction in the serum coagulant protein activity is reflected by an increase in the PT and PTT following the Hespan resuscitation, with this increase being statistically significant in those animals receiving 1.5 g/kg of Hespan supplementation (Table 3). The serum coagulant protein activity of Ic, IIc, and VIIIc was also decreased after Hespan resuscitation, with this decrease being significant at the higher dosages of Hespan infusion (Table 3). The decrease in the activity of these coagulant proteins is reflected by the increased number of seconds required for specific factor-deficient sera to clot in the Hespan-supplemented animals as compared to the RL group. The serum coagulant activity of ATIIIc and Pg was also decreased following Hespan resuscitation as reflected by a lower activity level in those animals receiving the higher

dosages of Hespan infusion (Table 3). A similar pattern in the serum coagulant protein activity was seen on day 3, with a significant prolongation in the PT and PTT associated with a reduction in Ic and VIIIc activity within the serum of the Hespan-resuscitated animals when compared to the RL group (Table 3).

The lymphatic concentrations of the coagulant proteins paralleled the LA and LG concentrations in most instances, but the differences between the Hespan resuscitated animals and the RL group often did not reach statistical significance (Table 4). However, there was a significant decrease in the PTT in one of the Hespan-resuscitated groups when compared to the RL group, thus indicating increased activity of the intrinsic coagulation proteins in the lymph of this Hespan group when compared to the RL group. There was also a significant increase in the Pg activity within the lymphatic juice of two of the Hespan-supplemented groups when compared to the RL group. No significant differences were observed in the lymphatic activity of Ic, IIc, or IIIc following the Hespan resuscitation, although there were insignificant increases in the activities of these coagulant proteins when compared to the RL group (Table 4).

Discussion

Prior randomized studies showed that addition of human serum albumin to the resuscitation regimen for hemorrhagic shock in humans increased SA and decreased the serum concentrations of nonalbumin proteins.[5,6] This included a decrease in immunoglobulin protein concentration and a concomitant decrease in coagulant protein concentration and activity.[5,17] This

latter decrease was associated with an increase in the number of blood transfusions needed to achieve the same red cell mass as the injured patients not receiving albumin supplementation.[6] The reduction in serum coagulant protein concentration and activity after albumin have been reproduced in dogs subjected to the same hemorrhagic shock insult reported herein.[4] Later studies showed that dogs receiving albumin supplementation had an increase in lymphatic protein concentration of the nonalbumin proteins.[18] This increased vascular efflux of nonalbumin proteins after albumin may result from an oncotic factor designed to maintain the optimal lymph:plasma protein ratio.[18] In theory, this optimal lymph:plasma protein ratio may be different for specific proteins depending upon molecular weight and geometric configuration and also for the specific time in the

multiphasic response to the hemorrhagic shock insult.[18] Few studies have serially monitored the lymph:plasma ratios of specific proteins after resuscitation from hemorrhagic shock so that an optimal ratio for a coagulant protein, an immunoglobulin, or any other nonalbumin protein exists only in theory. A more thorough understanding of the total shock insult mandates a more sophisticated approach to the total body protein changes during and after resuscitation.

Pending such studies, serial measurements of serum proteins provide the only guide to the efficacy of a resuscitation regimen. The present study reinforces the theory that the intravascular addition of any colloidal particle induces relocation of proteins into the interstitial fluid space, persumably to maintain a specific lymph to plasma oncotic balance. This is the first time that this relocation has been demonstrated after Hespan-supplemented resuscitation. This extravascular oncotic relocation included movement of the Hespan particles. Although Hespan concentrations were not measured, the lymph had increased particulate matter, with the greatest optical density seen in those animals that received the largest amount of Hespan. Thus, the oncotic factor leading to the extravascular relocation of oncotic particles drives all oncotic particles, including proteins and Hespan, from the capillary into the interstitial fluid space and then into the lymphatic channels. The end result is a decrease in all serum protein levels including, TSP, SA, SG, and the coagulant proteins. Although the significance of this reduction in coagulant protein activity was not fully tested herein, similar changes in man after albumin resuscitation were associated with the need for additional blood transfusions to achieve the same red cell mass as seen in patients not receiving albumin.[5] The clinical effects of reduced intravascular protein after Hespan resuscitation needs to be assessed in controlled studies. Pending such studies, Hespan-supplemented resuscitation should be suspected for causing multiple alterations in circulatory protein concentrations and functions due to an oncotically controlled extravascular protein relocation.

THE BILLINGS CLINIC

Certified Cardiopulmonary Perfusionist

Progressive medical center in the Northwest area is seeking a certified Cardiovascular Perfusionist. Qualifications: Applicant must be certified or eligible for certification as a Perfusionist; licensure as a registered nurse is helpful but not required; demonstrated ability to work effectively with cardiovascular team. Salary commensurate with experience, excellent benefits.

Forward resume to:

Personnel Manager
The Billings Clinic
P.O. Box 35100
Billings, MT 59107-5100.

Immediate Opportunity

Surgery

Group or solo practice

Affiliate with our progressive, well-equipped hospital and help us meet the needs of the 55,000 residents of our hospital district. Renovation ($6.6 million) of major areas including surgery now under way.

Income guarantees, relocation assistance and practice enhancement services provided.

Send current CV or call collect –

The classic atlas for surgeons—now in a new and updated edition

ATLAS OF SURGICAL OPERATIONS

SIXTH EDITION • By Robert M. Zollinger, Jr. and Robert M. Zollinger

For half a century, the *Atlas of Surgical Operations* has presented a standard of patient care and technical excellence that is the hallmark of the master surgeon.

The new sixth edition continues in this tradition with coverage of more than 200 standard and uncommon surgical procedures, presented in step-by-step fashion and accompanied by anatomical illustrations of unsurpassed clarity and accuracy.

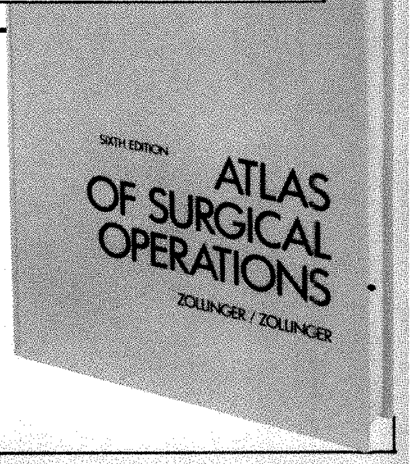
Thoroughly revised and updated, the new edition is effective as a guide and reference. A concise, lucid discussion of each procedure, with indications for surgery, preoperative preparations, anesthesias, position of patients, incisions and exposures, full procedural details, closures, and postoperative care, is given with corresponding illustrations on the facing page.

NEW IN THE SIXTH EDITION:

- **14 new surgical procedures**
- **20 new plates covering modified radical mastectomy, shouldice herniorraphy, ileonanal anatomosis, saphenous vein "in situ" arterial bypass, and parathyroidectomy**
- **a revised section on stapling**
- **a new chapter on ambulatory surgery**

"This atlas continues to be an excellent reference source for surgeons at any level of their development."
—*The New England Journal of Medicine* (on the Fifth Edition)

"A true classic on the American surgery scene... superb, detailed pen and ink drawings...the *Atlas of Surgical Operations* may approach Whitehead's classic trilogy of education: for the medical student a volume to stimulate the imagination, for the resident, it will ingrain discipline and provide a valuable guide, and for the practicing surgeon, it is a useful synthesis of these qualities thus providing a valuable reference for his daily work." —*Annals of Surgery* (on the Fifth Edition)



504 pages • durable cloth binding 10" x 14" • March, 1988 • $120.00 • ISBN 0-02-432070-6

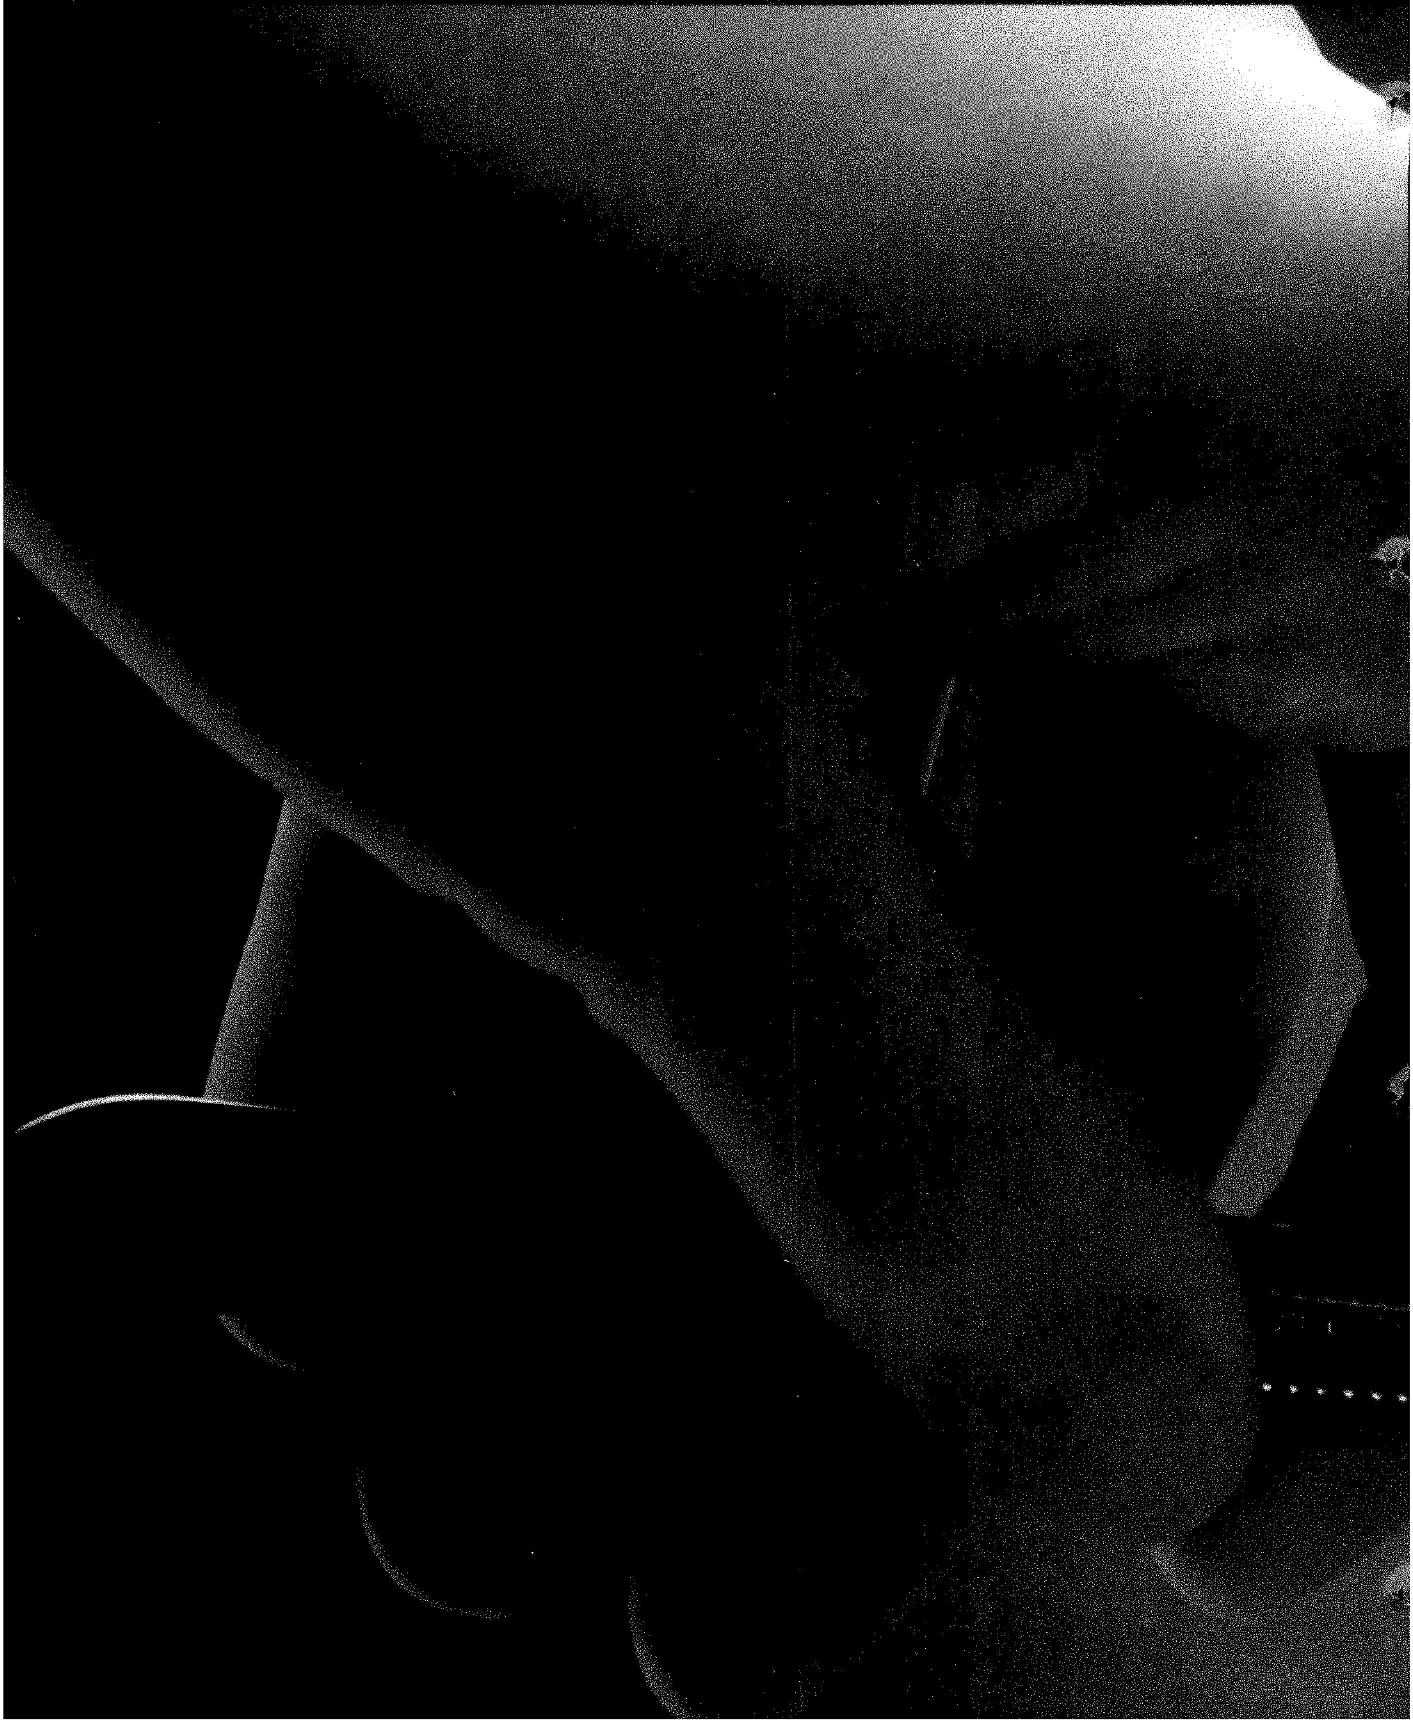
DEFINING A NEW STANDA



D* FOR EMPIRIC THERAPY

For Infection Following Complicated Abdominal Surgery

BETTER THAN AMINOGLYCOSIDE COMBINATIONS FOR MOST PATIENTS

☐ Anaerobic coverage of clindamycin or metronidazole plus

☐ Gram-negative coverage of an aminoglycoside plus

☐ Gram-positive coverage of cefazolin plus

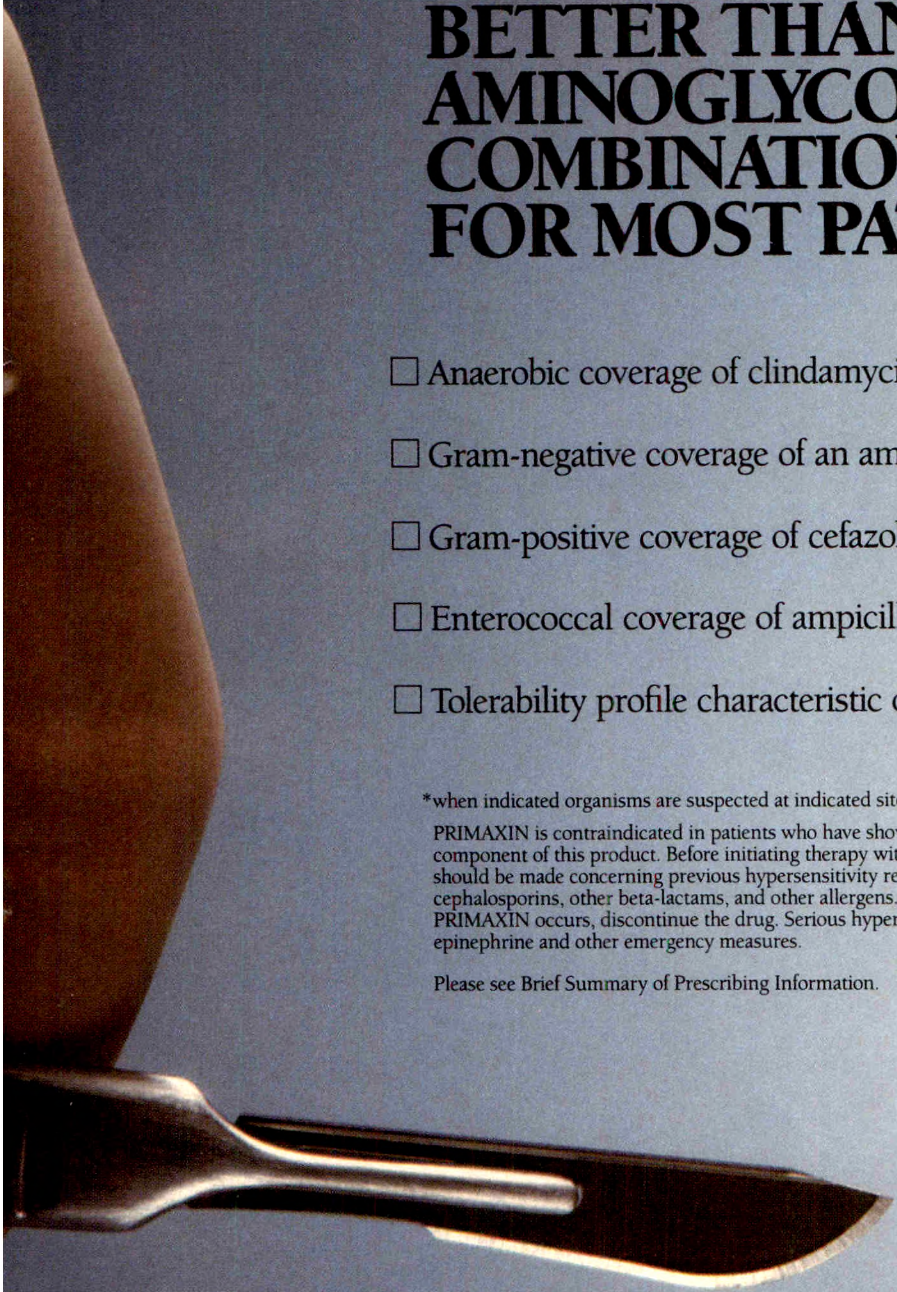
☐ Enterococcal coverage of ampicillin plus

☐ Tolerability profile characteristic of beta-lactam antibiotics

*when indicated organisms are suspected at indicated sites

PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product. Before initiating therapy with PRIMAXIN, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, other beta-lactams, and other allergens. If an allergic reaction to PRIMAXIN occurs, discontinue the drug. Serious hypersensitivity reactions may require epinephrine and other emergency measures.

Please see Brief Summary of Prescribing Information.



INTRAVENOUS

PRIMAXIN®

(Imipenem-Cilastatin Sodium|MSD)

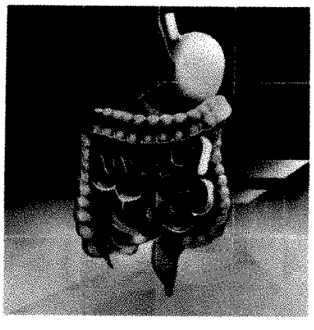
Copyright © 1988 by Merck & Co., Inc.

DEFINING A NEW STANDARD FOR EMPIRIC THERAPY

INTRAVENOUS

PRIMAXIN®

(Imipenem-Cilastatin Sodium/MSD)



Contraindications: PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product.

Warnings: SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (anaphylactic) REACTIONS HAVE BEEN REPORTED IN PATIENTS RECEIVING THERAPY WITH BETA LACTAMS. THESE REACTIONS ARE MORE APT TO OCCUR IN PERSONS WITH A HISTORY OF SENSITIVITY TO MULTIPLE ALLERGENS.

THERE HAVE BEEN REPORTS OF PATIENTS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE HYPERSENSITIVITY REACTIONS WHEN TREATED WITH ANOTHER BETA LACTAM. BEFORE INITIATING THERAPY WITH 'PRIMAXIN,' CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, OTHER BETA LACTAMS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION TO 'PRIMAXIN' OCCURS, DISCONTINUE THE DRUG. SERIOUS HYPERSENSITIVITY REACTIONS MAY REQUIRE EPINEPHRINE AND OTHER EMERGENCY MEASURES.

Pseudomembranous colitis has been reported with virtually all antibiotics, including PRIMAXIN; therefore it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use. This colitis may range in severity from mild to life threatening.

Mild cases of pseudomembranous colitis may respond to drug discontinuance alone. In more severe cases, management may include sigmoidoscopy, appropriate bacteriological studies, fluid, electrolyte, and protein supplementation, and the use of a drug such as oral vancomycin, as indicated. Isolation of the patient may be advisable. Other causes of colitis should also be considered.

Precautions: *General*—CNS adverse experiences such as confusional states, myoclonic activity, and seizures have been reported during treatment with PRIMAXIN, especially when recommended dosages were exceeded. These experiences have occurred most commonly in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function. However, there have been reports of CNS adverse experiences in patients who had no recognized or documented underlying CNS disorder or compromised renal function.

Patients with severe or marked impairment of renal function, whether or not undergoing hemodialysis, had a higher risk of seizure activity when receiving maximum recommended doses than those with no impairment of renal function; therefore, maximum recommended doses should be used only where clearly indicated (see DOSAGE AND ADMINISTRATION).

Patients with creatinine clearances of ≤ 5 mL/min/1.73 m^2 should not receive PRIMAXIN unless hemodialysis is instituted within 48 hours.

For patients on hemodialysis, PRIMAXIN is recommended only when the benefit outweighs the potential risk of seizures.

Close adherence to the recommended dosage and dosage schedules is urged, especially in patients with known factors that predispose to convulsive activity. Anticonvulsant therapy should be continued in patients with known seizure disorders. If focal tremors, myoclonus, or seizures occur, patients should be evaluated neurologically, placed on anticonvulsant therapy if not already instituted, and the dosage of PRIMAXIN re-examined to determine whether it should be decreased or the antibiotic discontinued.

As with other antibiotics, prolonged use of PRIMAXIN may result in overgrowth of nonsusceptible organisms. Repeated evaluation of the patient's condition is essential. If superinfection occurs during therapy, appropriate measures should be taken. While PRIMAXIN possesses the characteristic low toxicity of the beta-lactam group of antibiotics, periodic assessment of organ system function during prolonged therapy is advisable.

Drug Interactions—Since concomitant administration of PRIMAXIN and probenecid results in only minimal increases in plasma levels of imipenem and plasma half-life, it is not recommended that probenecid be given with PRIMAXIN.

PRIMAXIN should not be mixed with or physically added to other antibiotics. However, PRIMAXIN may be administered concomitantly with other antibiotics, such as aminoglycosides.

Carcinogenesis, Mutagenesis, Impairment of Fertility—Gene toxicity studies were performed in a variety of bacterial and mammalian tests *in vivo* and *in vitro*. The tests were: V79 mammalian cell mutation assay (PRIMAXIN alone and imipenem alone), Ames test (cilastatin sodium alone), unscheduled DNA synthesis assay (PRIMAXIN), and *in vivo* mouse cytogenicity test (PRIMAXIN). None of these tests showed any evidence of genetic damage.

Reproduction tests in male and female rats were performed with PRIMAXIN at dosage levels up to 8 times the usual human dose. Slight decreases in live fetal body weight were restricted to the highest dosage level. No other adverse effects were observed on fertility, reproductive performance, fetal viability, growth, or postnatal development of pups. Similarly, no adverse effects on the fetus or on lactation were observed when PRIMAXIN was administered to rats late in gestation.

Pregnancy—Pregnancy Category C: Teratogenicity studies with cilastatin sodium in rabbits and rats at 10 and 33 times the usual human dose, respectively, showed no evidence of adverse effect on the fetus. No evidence of teratogenicity or adverse effect on postnatal growth or behavior was observed in rats given imipenem at dosage levels up to 30 times the usual human dose. Similarly, no evidence of adverse effect on the fetus was observed in teratology studies in rabbits with imipenem at dosage levels at the usual human dose.

Teratology studies with PRIMAXIN at doses up to 11 times the usual human dose in pregnant mice and rats during the period of major organogenesis revealed no evidence of teratogenicity.

Data from preliminary studies suggest an apparent intolerance to PRIMAXIN (including emesis, inappetence, body weight loss, diarrhea, and death) at doses equivalent to the average human dose in pregnant rabbits and cynomolgus monkeys that is not seen in non-pregnant animals in these or other species. In other studies, PRIMAXIN was well tolerated in equivalent or higher doses (up to 11 times the average human dose) in pregnant rats and mice. Further studies are under way to evaluate these findings.

There are, however, no adequate and well-controlled studies in pregnant women. PRIMAXIN should be used only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers—It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when PRIMAXIN is administered to a nursing woman.

Pediatric Use—Safety and effectiveness in infants and children below 12 years of age have not yet been established.

Adverse Reactions: PRIMAXIN is generally well tolerated. Many of the 1,723 patients treated in clinical trials were severely ill and had multiple background diseases and physiological impairments, making it difficult to determine causal relationship of adverse experiences to therapy with PRIMAXIN.

Local Adverse Reactions—Local adverse clinical reactions that were reported as possibly, probably, or definitely related to therapy with PRIMAXIN were: phlebitis/thrombophlebitis (3.1%), pain at the injection site (0.7%), erythema at the injection site (0.4%), vein induration (0.2%), infused vein infection (0.1%).

Systemic Adverse Reactions—The most frequently reported systemic adverse clinical reactions that were reported as possibly, probably, or definitely related to PRIMAXIN were: nausea (2.0%), diarrhea (1.8%), vomiting (1.5%), rash (0.9%), fever (0.5%), hypotension (0.4%), seizures (0.4%) (see PRECAUTIONS), dizziness (0.3%), pruritus (0.3%), urticaria (0.2%), somnolence (0.2%).

Additional adverse systemic clinical reactions reported as possibly, probably, or definitely drug related occurring in less than 0.2% of the patients or reported since the drug was marketed are listed within each body system in order of decreasing severity: *Gastrointestinal*—pseudomembranous colitis (see WARNINGS), hemorrhagic colitis, gastroenteritis, abdominal pain, glossitis, tongue papillar hypertrophy, heartburn, pharyngeal pain, increased salivation; *CNS*—encephalopathy, tremor, confusion, myoclonus, paresthesia, vertigo, headache, psychic disturbances; *Special Senses*—transient hearing loss in patients with impaired hearing, tinnitus; *Respiratory*—chest discomfort, dyspnea, hyperventilation, thoracic spine pain; *Cardiovascular*—palpitations, tachycardia; *Renal*—oliguria/anuria, polyuria; *Skin*—erythema multiforme, facial edema, flushing, cyanosis, hyperhidrosis, skin texture changes, candidiasis, pruritus vulvae; *Body as a Whole*—polyarthralgia, asthenia/weakness.

Adverse Laboratory Changes—Adverse laboratory changes without regard to drug relationship that were reported during clinical trials or reported since the drug was marketed were: *Hepatic*—increased SGPT, SGOT, alkaline phosphatase, bilirubin, and LDH; *Hemic*—increased eosinophils, positive Coombs test, decreased WBC and neutrophils, including agranulocytosis, increased WBC, increased platelets, decreased platelets, decreased hemoglobin and hematocrit, increased monocytes, abnormal prothrombin time, increased lymphocytes, increased basophils; *Electrolytes*—decreased serum sodium, increased potassium, increased chloride; *Renal*—increased BUN, creatinine; *Urinalysis*—presence of urine protein, urine red blood cells, urine white blood cells, urine casts, urine bilirubin, and urine urobilinogen.

NOTE: Due to the high antimicrobial activity of PRIMAXIN, it is recommended that the maximum total daily dosage not exceed 50 mg/kg/day or 4.0 g/day, whichever is lower.

How Supplied: PRIMAXIN is supplied as a sterile powder mixture in vials, infusion bottles, and single-dose ADD-Vantage®*† vials containing imipenem anhydrous and cilastatin sodium as follows: 250 mg imipenem equivalent and 250 mg cilastatin equivalent; 500 mg imipenem equivalent and 500 mg cilastatin equivalent.

Caution: The suspension from vials is not for direct infusion.

A Kinetic Study of Leucine Metabolism in Severely Burned Patients

Comparison Between a Conventional and Branched-Chain Amino Acid–Enriched Nutritional Therapy

YONG-MING YU, M.D., DAVID A. WAGNER, PH.D., J. C. WALESRESWSKI, M.D.,
JOHN F. BURKE, M.D., and VERNON R. YOUNG, PH.D., D.SC.

A cross-over design study was used to examine the metabolic consequences of enteral feeding for 48 to 96 hours with either a branched-chain amino acid (BCAA)-enriched (44% BCAA) or a conventional egg protein formulation in 12 severely burned adult patients. A stable isotope labeled leucine (L-1-^{13}C-leucine) tracer approach was used to measure leucine flux and oxidation and to estimate rates of whole body protein synthesis and breakdown. Additionally, $^{15}N_2$-urea and 6,6-^{2}H-glucose were administered to assess the status of urea and glucose kinetics with these two nutritional treatments. Average patient age was 54 years, and average burn surface area was 36%. Studies were conducted at an average of 25 days postburn. Leucine flux and oxidation were significantly ($p < 0.01$, by paired t-test) elevated with BCAA feeding as compared to the egg protein formulation. However, there were no significant differences in the rates of leucine incorporation into, or release from, proteins ($p > 0.05$) between the two dietary periods. Mean rates of body protein synthesis and breakdown for each diet were about twice the rates reported for healthy young adults. Apparent nitrogen balance measurements were not statistically different ($p > 0.1$) between the two diet periods. Furthermore, urea and glucose kinetics failed to show significant differences between the two diet periods. It appears from these results that the major consequences of increased intake of leucine from the BCAA formula is an enhanced rate of leucine oxidation. In conclusion, (1) the availability of BCAAs is not rate-limiting for enhanced protein synthesis in burn patients, and (2) the use of enriched BCAA formulas in burn therapy does not appear to offer advantages over a routinely used enteral egg protein formula, at least based on the present determinations.

From the Department of Surgery, Massachusetts General Hospital and Shriners Burns Institute, Boston, Massachusetts, and the Laboratory of Human Nutrition, Department of Applied Biological Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts

MAJOR THERMAL INJURY metabolism is characterized by an increased rate of body protein breakdown and elevated energy expenditure,[1] impaired use of glucose,[2,3] and alterations in the metabolism of lipid substrates.[4,5] A number of studies have suggested that increasing the exogenous supply of branched-chain amino acids (BCAAs) might minimize the overall catabolic state under conditions of severe trauma and that this would be of benefit in the overall treatment of trauma patients (*e.g.*,[6–8]). This has been proposed, in part, because (1) leucine has been shown to promote protein synthesis and inhibit protein breakdown when the amino acid is added to incubated muscle preparations,[9,10] and (2) there is an increased rate of BCAA oxidation in trauma patients, possibly creating a deficit in the availability of leucine for purposes of meeting substrate needs for protein synthesis.[11] To date, studies conducted to evaluate the possible advantages of supplying BCAA-enriched nutritional formulations to trauma patients have mainly utilized the nitrogen balance technique,[12,13] as well as monitoring amino acid profiles in blood and the arteriovenous-amino acid concentration differences across the limbs.[14–16] However, the findings so far have been inconsistent,[17,18] and there have been no studies designed to directly explore the aforementioned hypothesis.

The present study used a stable isotope labeled leucine (L-1-^{13}C-leucine) tracer approach and a cross-over design to examine the metabolic consequences of using a BCAA-enriched enteral feeding, as compared to a conventional egg protein formulation, in 12 severely burned patients. In addition, the tracers $^{15}N_2$-urea and 6,6-^{2}H-glucose were used in seven of these 12 patients to assess the status of urea and glucose kinetics under the two conditions of nutritional support. Using these tech-

Values in parentheses refer to the order in which BCAA was received, namely, either during first (I) or second (II) period.

IBW = ideal body weight based on 1959 Metropolitan Life Insurance Company Tables.

BSA = burn surface area.

PBD = postburn days.

niques we were able to investigate whether a BCAA-enriched diet improves net protein balance in burn patients and, if so, whether this was achieved by a stimulation of protein synthesis and/or inhibition of body protein breakdown.

Materials and Methods

Materials

L-1-^{13}C-leucine (99% ^{13}C), ^{15}N-urea (99%, ^{15}N), and 6,6-^{2}H-glucose (98% ^{2}H) were purchased from KOR Isotopes, Cambridge, MA and $NaH^{13}CO_3$ (99% ^{13}C) from Prochem, Summit, NJ. Solid whole egg and egg white were obtained from the dietary department of the Massachusetts General Hospital. The BCAA-enriched amino acid mixture, carbohydrate, fat, trace mineral, and vitamin supplements used for the enteral formulation were obtained from a commercial supplier (Sandoz Nutrition Corporation, Minneapolis, MN). The isotopes were prepared and infused, using sterile techniques after having been proved sterile and pyrogen-free as previously described.[19]

Patients

Twelve severely burned patients participated in this study. Written consent was obtained from each patient after they were carefully informed of the purpose, design, and possible hazards of the experiment. Clinical details for the patients are given in Table 1.

Study Design

Each study was performed when the patient was in a relatively stable condition, as demonstrated by stable vital signs, including blood pressure, respiration rate, oral temperature, normal liver and kidney function, and absence of clinical signs of general infection and septicemia.

A cross-over experimental design was used, with each patient being studied during two consecutive dietary periods. One of these involved an egg and carbohydrate enteral feeding regimen of the kind routinely used at this center; the other was a BCAA-enriched enteral feeding formulation. Each dietary period lasted 48–96 hours (Fig. 1), at the end of which a 2-hour stable isotope infusion study was performed. The order in which the patients received the two nutritional support systems was random. The patients had received an enteral feed-

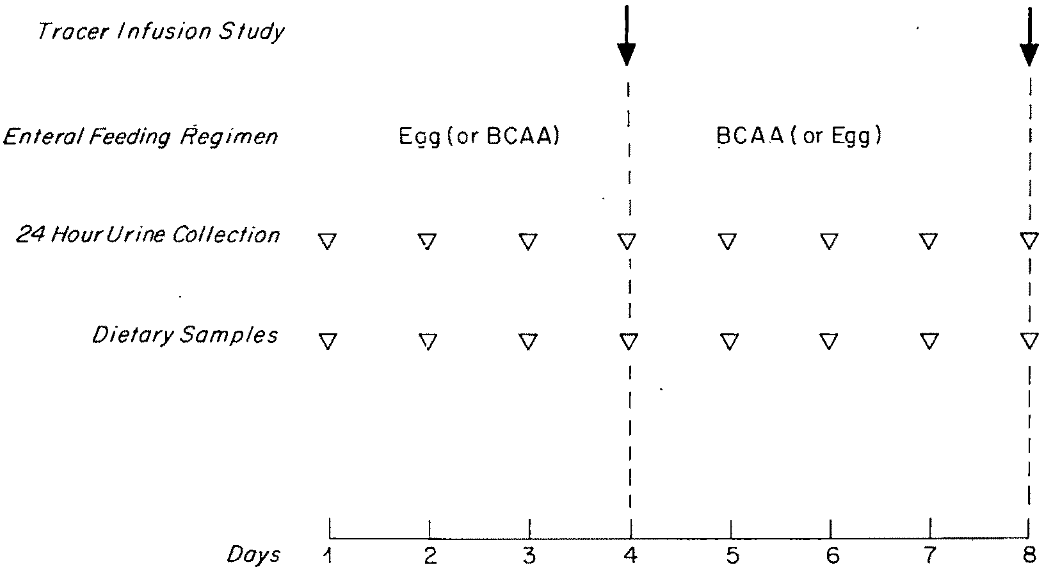

FIG. 1. Schematic outline of study design. Each patient was studied during two dietary periods, one being a BCAA-enriched formula and the other based on an egg protein. Each diet period lasted 2–4 days.

ing of a conventional egg-protein-polycose diet for at least 5 days before the cross-over study began. The amounts of nitrogen and energy supplied during this earlier period were essentially the same as during the experimental period. The experimental protocol was approved by the Human Study Committee of the Massachusetts General Hospital. A graphic description of the major features of the experimental design is given in Figure 1.

Enteral Feeding Regimens

Two nutritional formulations were used in the present study (Table 2). The principal difference between the two diets is related to the composition of the protein source: (1) a mixture of egg white and whole egg powder, containing about 20% (w/w) of BCAA, or (2) a BCAA-enriched amino acid mixture, containing 44% (w/w) of BCAA (Table 3). Nitrogen intake was 0.26 ± 0.02 gN $kg^{-1} \times d^{-1}$ for the egg diet and 0.24 ± 0.02 gN $kg^{-1} \times d^{-1}$ for the BCAA diet. Average energy intakes for each diet period were (mean ± SEM), 40 ± 3 kcal $\times kg^{-1} \times d^{-1}$ for the egg diet and 40 ± 2 kcal $kg^{-1} \times d^{-1}$ for the BCAA diet. Carbohydrate intake was calculated to be equivalent to about 5 mg glucose $kg^{-1} \times min^{-1}$, with the remainder of the energy being supplied by fat. The diets were prepared in the dietary department of Massachusetts General Hospital. Both diets were administered enterally via an indwelling nasogastric tube, using an infusion pump (Model 927, IMED Corporation, San Diego, CA).

Infusion Studies

All tracer studies were conducted while the patients were in the fed state. The isotopes were infused through an existing central venous catheter and blood samples were withdrawn from previously placed arterial lines. Before the isotope infusion period was started, blood and expired air samples were taken for measurement of background isotope enrichments of leucine, α-ketoisocaproate (KIC), urea, and glucose in the plasma and of $^{13}CO_2$ in the expired air. Then, the primed-constant infusions of L-1-^{13}C-leucine, $^{15}N_2$-urea, and 6,6-^{2}H-glucose were started, together with a simultaneous priming dose of $NaH^{13}CO_3$ (9.2 μmol). The approximate, but known, infusion rates of the isotopic tracers were 0.65 mmol $\times h^{-1}$ for L-1-^{13}C-leucine, 1.2 mmol $\times h^{-1}$ for $^{15}N_2$-urea, and 1.2 mmol $\times h^{-1}$ for 6,6-^{2}H-glucose. The priming doses for these tracers were 0.65 mmol, 12 mmol, and 1.6 mmol, respectively. The isotope infusion period lasted for 120 minutes. Additional details have been described earlier,[19] and a schematic outline of the tracer infusion protocol is shown in Figure 2.

Analytic Methods

The isotopic enrichment of leucine was determined by isolation of the free amino acid from plasma and derivatization to the N-acetyl, n-propyl (NAP) ester.[20] The L-1-^{13}C-leucine was analyzed on a Hewlett-Packard 5985B quadruple mass spectrometer, using positive chemical ionization with methane as the reagent gas, with selected ion monitoring at $M/Z = 216$ and 217. A 12-m × 0.20 mm ID, OV-1 capillary column, using helium as a carrier gas, was used in the gas chromato-

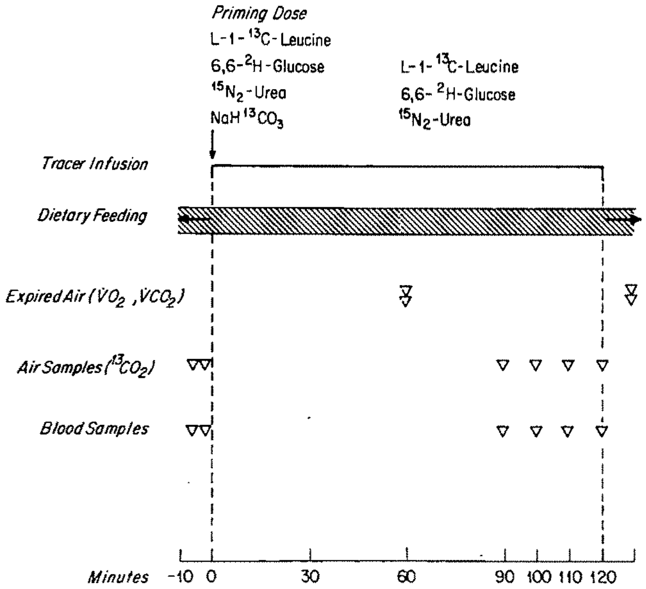

FIG. 2. Schematic outline of tracer infusion protocol. The total infusion period was 120 minutes. For the isotopic plateau level, plasma and air samples were collected between 90 and 120 minutes.

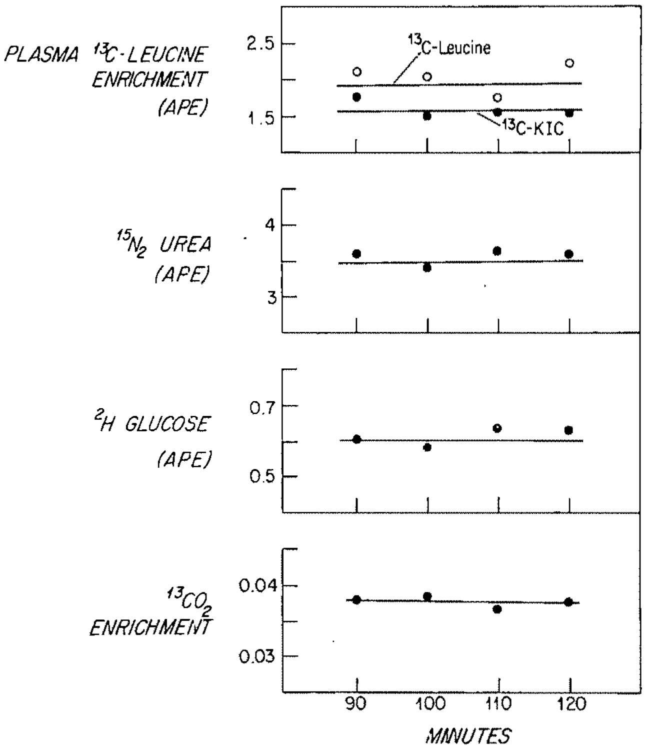

FIG. 3. An example of the plateau level of isotope enrichments for L-1-^{13}C-leucine, 1-^{13}C-KIC, ^{15}N-urea, 6,6-^{2}H-glucose in plasma, and $^{13}CO_2$ enrichment in expired air for one patient.

graph. The enrichment of the isotope was calculated according to Matthews et al.[21] α-Ketoisocaproic acid was isolated from the same plasma sample as those used for leucine analysis. L-1-^{13}C-Ketoisocaproic acid was determined by conversion to a t-butyl-silylquinoxalinol derivative. This is a slight modification of a previously published method,[22] with the t-butyl-silyl group formed by the addition of MTBSTFA (Pierce Chemical Company, Rockford, IL) rather than BSTFA. Electron impact ionization was used on a Hewlett-Packard 5970 instrument, with selected ion monitoring of $M/Z = 259$ and 260 [MW-57 for unlabeled and labeled α-ketoisocaproic acid]. A similar capillary column for the gas chromatography was used as described previously. The deuterated glucose[23] and $^{15}N_2$-urea samples[24] were analyzed by electron impact ionization, as described previously.

Enrichments of all compounds were calculated as atom per cent excess, relative to natural background levels of isotope. All samples were run in duplicate. If the results did not reproduce within 5%, the samples were reinjected two additional times.

Expired air samples were used to measure VO_2 and VCO_2 levels, as described previously.[19] Air samples were analyzed for $^{13}CO_2$ enrichment, using a dual collector isotope ratio mass spectrometer (Nuclide Corp., State College, PA). Atom per cent excess (APE) of $^{13}CO_2$ was determined relative to the reference carbon dioxide derived from potassium carbonate. The baseline $^{13}CO_2$ values were subtracted from each plateau sample to give a relative atom per cent excess $^{13}CO_2$.

Amino acid concentrations in plasma and infusates were measured by conventional automated ion-exchange chromatography with the aid of an automated amino acid analyzer (Model 119 CL, Beckman Instruments, Palo Alto, CA).

Complete urine samples were collected and pooled for each 24 hours and the total volume was recorded. The concentration of urinary creatinine was determined,[25] and the total nitogen content of urine and diets was measured by the Kjeldahl method.[26] The amino acid composition of the whole egg and egg white solids was determined through the courtesy of Dr. C. E. Bodwell, USDA Human Nutrition Institute, Beltsville, MD.

Calculations

In all of the tracer experiments, isotopic equilibrium appeared to be reached within 90 minutes, as demonstrated by a stable level of isotope enrichment in plasma of L-1-^{13}C-leucine, 1-^{13}C-KIC, $^{15}N_2$-urea, and 6,6-^{2}H-glucose and $^{13}CO_2$ in expired air (*e.g.*, Fig. 3). Therefore, the equations used for the calculations of leucine, glucose, and urea fluxes were based on steady-state conditions.

In order to take into account the differences between the isotopic abundance of plasma-free leucine and that of the intracellular precursor pool,[27] the whole body leucine flux was calculated from measurements of plasma 1-^{13}C-KIC enrichment,[27–29] according to the following equation[30]:

$$Ra_{leu} = \left(\frac{Ei}{Ep} - 1\right) i,$$

where Ra = plasma leucine flux (μmol × kg^{-1} × h^{-1}), Ei = the ^{13}C-leucine enrichment in the infusate (APE), Ep = plasma 1-^{13}C-KIC enrichment (APE), and i = the rate of isotope infusion (μmol kg^{-1} × h^{-1}).

The same general equation was applied for estimating urea and glucose fluxes.

The rates of whole body protein synthesis and protein breakdown were calculated assuming an average leucine content in whole body proteins of 590 μmol/g protein.[31,32] Leucine oxidation was determined from the total CO_2 production rate, the $^{13}CO_2$ enrichment in the expired air, and the plasma 1-^{13}C-KIC enrichment, as described previously.[19,33]

Apparent nitrogen balances were calculated from the difference between the total intake and urinary output of nitrogen.

Evaluation of Data

The energy expenditure of the patients was evaluated by indirect calorimetry.[19] The daily expenditure was taken as the value obtained during the infusion period and extrapolated for the 24 h of the day. Paired t-tests were used to assess the differences in leucine kinetics and energy expenditure between the two dietary periods.

Results

Energy expenditure and the general clinical condition of the patients did not appear to differ significantly between the two dietary periods for each of these 12 patients. For the entire group, energy expenditure (mean ± SEM) was 32 ± 2.4 kcal × kg^{-1} × d^{-1}. This approximates 140% of the predicted basal metabolic rate (Table 4). In all cases energy expenditure was less than the energy provided by the enteral feeding. Therefore, the patients appeared to be in apparent positive energy balance.

Plasma BCAA concentrations showed the anticipated increase when patients received the BCAA diet, as compared to those when they received the egg protein diet (Fig. 4).

Leucine kinetics were examined in all 12 patients while they were in the fed state (Table 5). To assess and compare the effect of the two nutritional support regimens, the following parameters were examined: (1) the difference between the rate of incorporation of leucine into proteins and the rate of appearance of leucine via protein breakdown for each dietary period; this difference is defined as leucine balance; (2) the difference between the leucine balances during the two dietary periods (*i.e.*, balance during the BCAA period minus that for the egg protein period).

TABLE 4. *Energy Expenditure of the Burn Patients*

Patient No.	Total Energy Expenditure (kcal kg^{-1} d^{-1}) EGG	BCAA	BMR (Estimated)

All values are given as μmol × kg^{-1} × h^{-1}.

* Significantly different, $p < 0.01$ (by Student's t-test), from egg diet period.

t-test) between these two dietary periods (Table 5). However, the differences (either positive or negative) in leucine balance between the two dietary periods within individuals were negatively correlated with the differences in rates of release of leucine from protein breakdown ($r = 0.6$; $p < 0.05$).

BCAA feeding resulted in significantly ($p < 0.01$) higher levels of leucine flux and oxidation, as compared with the traditional egg protein formulation. From these results it appears that the major consequences of the increased intake of leucine was an enhanced rate of leucine oxidation.

Apparent nitrogen balance (Table 6) data in these 12 patients did not reveal any statistical difference between these two dietary periods ($p > 0.1$). In addition, urea and glucose kinetics (Table 7) failed to show significant differences between these two dietary periods ($p > 0.1$ paired t-test). Because the studies in the first seven patients did not show differences, we chose not to include an assessment of urea and glucose kinetics in the additional five patients. In accordance with these results, glucose and urea concentrations (Fig. 5) were similar between the two dietary periods.

From the present leucine kinetic data it can be estimated that the mean rates of whole body protein synthesis and breakdown were about to 7.1 g protein kg^{-1} d^{-1} for the egg protein period and about 8.4 g kg^{-1} d^{-1} for the BCAA period. These values are approximately double those reported for healthy young adults,[28,33,34] confirming that the rate of body protein turnover is substantially increased in severely burned patients.[19,34]

Discussion

The present experiment was conducted in 12 severely burned nonseptic patients using a cross-over design in which each patient served as his or her own control in order to compare the metabolic responses to the two enteral formulations. A cross-over design was used to help minimize complications introduced by significant variations in the clinical and metabolic condition between patients and within each trauma patient over time.

Additionally, we used a relatively brief experimental dietary period, lasting 48–96 hours, and the order of the two periods was randomized. Clinical records revealed that for each patient there was little apparent difference in their condition between the two dietary periods, and this should permit a closer evaluation of the two enteral formulations. Of course, the brief length of the experimental study periods might be regarded as a limitation, but longer periods would introduce further problems for experimental design and interpretation.

It should be noted that the present study compared leucine kinetics and nitrogen balance in patients receiving two different formulas; these were not identical in all respects other than for the differences in BCAA levels. Thus, in one, an intact protein was the source of nitrogen and indispensable amino acids and in the other, it was a mixture of L-amino acids enriched with BCAA. Our choice of comparing these formulations was because it was important to use in one case a formulation routinely used in our clinical unit so that a potentially practical comparison could be then made with an amino acid mixture enriched with BCAAs. This latter formulation has been considered by some investigators[5–8,35] to offer possible advantages over conventional therapies for supporting protein metabolism in severely ill or catabolic patients, although no studies have made comparisons directly with conventional nutritional treatments. Clearly, it is possible that different results might have been obtained in our study if both of the formulations had been based on L-amino acid mixtures. Therefore, the present results should be considered in this context.

Some *in vitro* studies using incubated muscle preparations have revealed that higher concentrations of BCAAs in the incubation medium stimulate protein synthesis and decrease protein breakdown.[9,10] From such observations it has been hypothesized that a beneficial effect of leucine supplementation might be obtained in trauma patients. However, our *in vivo* leucine kinetic data fail to support this hypothesis. The present study demonstrated that a BCAA-enriched diet does not significantly alter the rate of leucine incorporation into, or release from, protein and, furthermore, that there was no measurable improvement in net body protein balance.

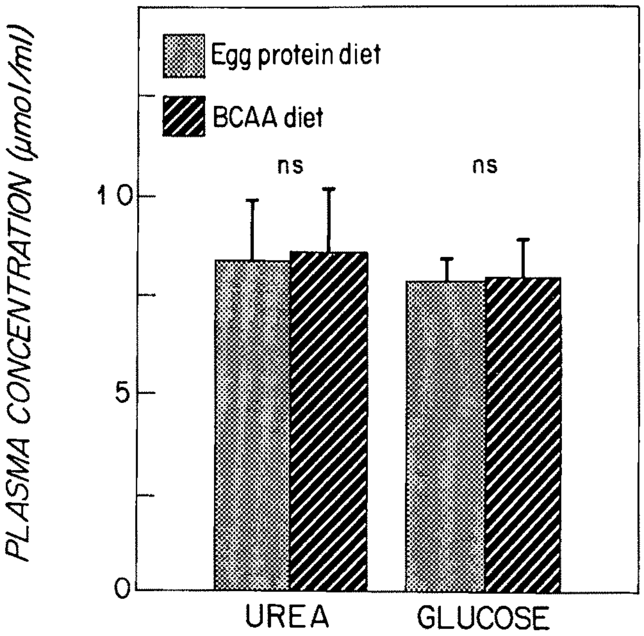

FIG. 5. Plasma glucose and urea concentration in patients during the egg protein and BCAA diet periods.

Previous studies have reported a significantly increased rate of plasma leucine disappearance and peripheral uptake rate of an exogenously infused leucine load in injured patients.[14–16] Because leucine and other BCAAs are oxidized to a significant extent in muscle, these earlier findings have been interpreted as reflecting an increased oxidation of BCAAs following trauma.[14–16] In combination with other findings, which show an impaired utilization of carbohydrates and fat as energy sources in trauma patients,[4,5,36] it has been proposed that BCAAs are consumed as a substitute fuel[5,11] and that this creates a deficit of BCAA availability for protein synthesis. With the aid of a leucine tracer, we have examined in the present study the metabolic fate of leucine in burn patients when given two different levels of BCAA support. It was possible, therefore, to evaluate the merits of this *BCAA deficit* hypothesis. Because rates of protein synthesis and breakdown both were found to be higher than for healthy, normal subjects, it is difficult to see that a deficit in the supply of leucine could be responsible primarily for the changes in amino acid and protein metabolism following burn injury.

Our investigation has further demonstrated that an enriched supply of BCAAs to burn patients does not significantly enhance the rate of leucine incorporation into proteins. Hence, we are unable to offer any evidence in favor of the hypothesis that the availability of BCAA is a rate-limiting factor for protein synthesis in burn patients. In parallel with these *in vivo* findings, there are reports[37–39] showing that the intracellular

BCAA concentrations in muscle are significantly elevated, rather than being depressed, in trauma patients. This may be a consequence of changes in leucine transport mechanisms or increased tissue proteolysis in response to trauma. Nevertheless, it would appear that a depletion of the intracellular free leucine pool is not a primary factor responsible for a reduced muscle protein balance under these conditions.

In addition, it has been proposed that BCAAs could substitute for other fuels in trauma patients and that a nitrogen-sparing effect[6,7,40] would be achieved by supplying higher than usual intakes of BCAA. Again, the results from the present study do not support this contention. Although we found that the rate of leucine oxidation was about double that with the BCAA diet, in comparison to the egg diet, this increase was not accompanied by any significant reductions in glucose flux or urea production. Clearly, the increased BCAA intake did not measurably influence the rate of glucose utilization, nor did it appear to spare body nitrogen loss by inhibiting proteolysis or improving nitrogen retention. Others have found that total BCAA oxidation accounts for about 2–5% of total energy expenditure.[41,42] Hence, the observed increase in leucine oxidation caused by BCAA feeding in the present study could only account for, at most, 4–10% of total energy expenditure for these patients.

Finally, it has been suggested that BCAA-enriched nutritional support may be of greater benefit in more severe cases of trauma. From our findings, it is difficult for us to offer support for this view. In the present study, differences in leucine balance between the BCAA and egg protein diets were not well correlated with the total burn area, the catabolic index[43] (data not shown), the nitrogen balance, or the leucine balance *per se*.

In summary, the present findings failed to show that a BCAA-enriched enteral feeding brings about additional metabolic benefits over those obtained with a more conventional, balanced, egg protein feeding. Thus, the BCAA treatment did not reveal consistent effects on protein synthesis or protein breakdown, as judged from the data on leucine kinetics. Indeed, protein synthesis rates in burn patients were high, irrespective of the nitrogen source of the feeding. Therefore, there is little reason to accept the idea that a primary deficency in the availability of BCAAs is responsible for the catabolic state of nitrogen metabolism under these conditions. Our conclusions are consistent with the findings of Milliken et al.,[18] who explored the effects of BCAA-enriched formulas in patients with cirrhosis. These investigators found with these formulas that there was an increased rate of leucine oxidation without an improvement in protein synthesis. Furthermore, Brennan et al.[44] have concluded, based on a the proceedings of a workshop concerned with BCAA supplementation in the nutritional therapy of hospitalized patients, that greater benefits must be demonstrated in man before any widespread application of the use of BCAA formulations can be recommended.

Acknowledgments

The authors gratefully acknowledge the assistance of Amanda Goldstein, R.N., and Mary Ellen Devereaux, for conducting the infusion studies; Christine Jacobson, R.D., for preparing the diets; and Knut Greulich and Tricia Smith for technical assistance. We thank Mrs. Betty Griffin for help in preparing the manuscript.

The Relationship Between Primary Hyperparathyroidism and Diabetes Mellitus

MICHAEL P. BANNON, M.D., JON A. VAN HEERDEN, M.B., CH.B., F.A.C.S.,
P. J. PALUMBO, M.D., and DUANE M. ILSTRUP, M.S.

Previous reports have suggested that control of diabetes improves after successful parathyroidectomy for primary hyperparathyroidism. To investigate this proposition further, a review was made of all insulin-requiring diabetics undergoing curative parathyroidectomy at the Mayo Clinic between 1970 and 1984 (36 patients). All contemporary insulin-requiring diabetics undergoing thyroidectomy for benign euthyroid disease served as a control group (34 patients). One patient in each group had type I diabetes mellitus, and the remainder had type II diabetes mellitus. Preoperative insulin requirements, insulin requirements at follow-up, and change in insulin requirements did not differ significantly between the two groups. This study suggests that parathyroidectomy does not lead to a statistically significant reduction in the insulin requirements of diabetic patients with primary hyperparathyroidism and that coexistent type II diabetes mellitus should not be considered a further indication for parathyroidectomy in patients with primary hyperparathyroidism.

PREVIOUS REPORTS have suggested that control of diabetes improves after parathyroidectomy for hyperparathyroidism.[1-3] These reports have included patients with both primary and secondary hyperparathyroidism and both insulin-requiring and non-insulin-dependent diabetics. The total number of patients reported in these series who demonstrated decreased insulin requirements after parathyroidectomy was small, and no reports have used control groups. To clarify the effect of parathyroidectomy on glycemic control in diabetic patients with primary hyperparathyroidism, we compared preoperative and postoperative insulin dosages in two contemporary groups of insulin-requiring diabetics. One group underwent parathyroidectomy for primary hyperparathyroidism, and a control group underwent thyroidectomy for benign euthyroid disease.

Patients and Methods

All insulin-requiring diabetics undergoing either curative parathyroidectomy for primary hyperparathyroidism or thyroidectomy for benign euthyroid disease between 1970 and 1984 were identified through a computer-based indexing system. Of the 70 patients identified, 36 had primary hyperparathyroidism and underwent parathyroidectomy (for adenoma in 32 and for hyperplasia in four), and 34 had benign euthyroid disease and underwent partial thyroidectomy (for multinodular goiter in 21 and for single or multiple thyroid adenomas in 13). All patients undergoing thyroid resection had normal preoperative total thyroxine levels, and none had a history of hyperthyroidism. Preoperative calcium values were normal in all patients undergoing thyroid resection, and no thyroid resection was associated with more than a minimal transient decrease in the postoperative serum calcium level. Review of pathology reports confirmed that all thyroid resections were performed without inadvertent excision of parathyroid tissue.

Patient records were reviewed to determine the age at onset, duration of diabetes, presence of a history of ketoacidosis, duration of insulin therapy, preoperative insulin dose, and preoperative weight. Instances of postoperative hypoglycemia, defined as any blood glucose determination of less than 40 mg/dL obtained within 5 days of operation, were recorded. Because all the patients were evaluated by staff endocrinologists before hospital admission, the appropriateness of their insulin therapy was ensured. Follow-up insulin doses and weights were obtained through review of the record or through con-

TABLE 1. *Clinical Data from 70 Patients with Diabetes Mellitus, by Type of Disease*

Factor	Thyroid Disease Hyperparathyroidism	 Benign Euthyroid	P Value
No. of patients			
Male	12	10	0.72
Female	24	24	
Mean age (yr)	60.5	61.1	0.86
Mean duration of diabetes mellitus (mo)	152	142	0.78
Mean duration of insulin therapy (mo)	90	87	0.38

tact with the patient or referring physician. Comparisons between the two groups were made with either chi square analysis or Fisher's exact test for discrete variables and with Student's t-tests and Wilcoxon rank-sum tests for continuous variables.

Results

The parathyroidectomy group consisted of 12 men (33%) and 24 women (67%), and the thyroidectomy group consisted of 10 men (29%) and 24 women (71%) (p = 0.72). The mean age of the patients was 60.5 years in the parathyroidectomy group and 61.1 years in the thyroidectomy group (p = 0.86). The duration of diabetes was similar in the two groups (152 months in the parathyroidectomy group and 142 months in the thyroidectomy group, p = 0.78); the duration of insulin therapy was also similar (90 months and 87 months, respectively, p = 0.38) (Table 1). Both groups included one patient with juvenile-onset diabetes mellitus; both of these patients had histories of ketoacidosis (type I diabetes mellitus). All other patients had adult-onset diabetes mellitus without a history of ketoacidosis (type II diabetes mellitus).

Follow-up insulin doses were determined for 32 (89%) of the 36 patients in the parathyroidectomy group, and the average duration of follow-up in this group was 6.0 years (range: 2 months to 13 years); follow-up doses were determined for 28 (82%) of the 34 patients in the thyroidectomy group, and the average duration of follow-up was 7.8 years (range: 1–16 years). Four patients in the parathyroidectomy group and six patients in the thyroidectomy group were lost to follow-up. No correlation was noted between change in the insulin dose and duration of follow-up (Fig. 1). Weight at follow-up was obtained in 30 (83%) of the patients in the parathyroidectomy group and 27 (79%) of the patients in the thyroidectomy group, and the average durations of follow-up were 5.8 years and 8.2 years, respectively. No correlation was noted between change in weight and duration of follow-up (Fig. 2).

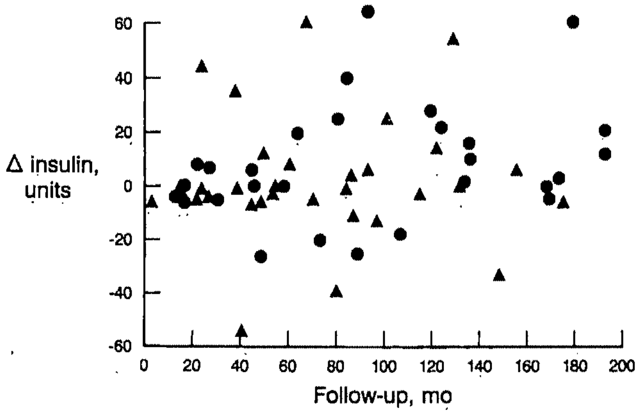

FIG. 1. Relationship of change in insulin dose and duration of follow-up in diabetic patients after parathyroidectomy (▲) and after thyroidectomy (●).

The mean insulin doses preoperatively and at follow-up were 37.2 units and 39.2 units/24 hours, respectively, for the parathyroidectomy group; the mean change in insulin dose was +2.1 units (SD: 23.2 units). Corresponding doses for the thyroidectomy group were 35.0 units and 43.1 units/24 hours; the mean change in dose was +9.6 units (SD: 22.6 units). Differences between the two groups were not statistically significant with respect to insulin dose preoperatively (p = 0.99) or at follow-up (p = 0.40). On average, 24-hour insulin doses increased by 7.5 units more in the thyroidectomy group than in the parathyroidectomy group (9.6 units *vs.* 2.1 units). This difference was not statistically significant (p = 0.21) (Table 2). At one extreme, the 95% confidence interval for this difference includes a mean increase in insulin dose of 19.5 units more for the thyroidectomy group than for the parathyroidectomy group. At the other extreme, the mean increase in insulin dose for the thyroidectomy group was 4.5 units less than that for the parathyroidectomy group. Figures 3 and 4 demonstrate the changes in insulin dose for patients in each group.

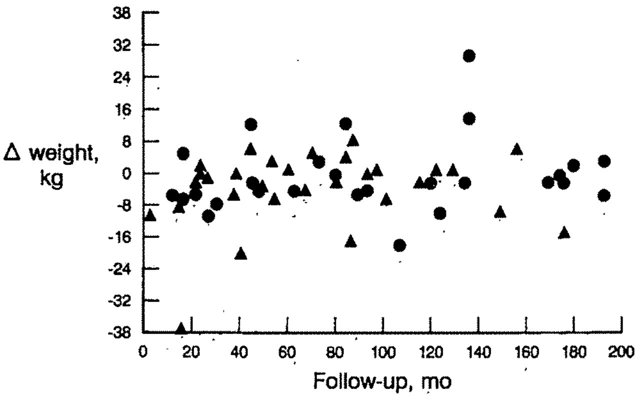

FIG. 2. Relationship of change in body weight and duration of follow-up in diabetic patients after parathyroidectomy (▲) and after thyroidectomy (●).

TABLE 2. *Insulin Dosages in 70 Patients with Diabetes Mellitus, by Type of Disease*

Time of Determination	Hyperparathyroidism		Benign Euthyroid Disease		P Value
	No. of Patients	Mean Dose (units/24 h)	No. of Patients	Mean Dose (units/24 h)	
Preoperatively	36	37.2	34	35.0	0.99
At follow-up	32	39.2	28	43.1	0.40
Change	32	+2.1	28	+9.6	0.21

Of the two patients with type I diabetes mellitus, the patient in the parathyroidectomy group experienced a decrease in insulin requirement of 3 units/day, and the patient in the thyroidectomy group experienced a decrease of 6 units/day.

The mean body weights preoperatively and at follow-up were 72.9 kg and 68.5 kg, respectively, for the parathyroidectomy group; the mean change in body weight was −3.4 kg. Corresponding weights for the thyroidectomy group were 73.5 kg, 72.1 kg, and −0.2 kg. The differences between the two groups were not statistically significant with respect to preoperative weight (p = 0.37), weight at follow-up (p = 0.32), or change in weight (p = 0.19) (Table 3).

Postoperative hypoglycemia occurred in one patient in the parathyroidectomy group but in none of the patients in the thyroidectomy group. Of those patients who had follow-up data, two (6%) in the parathyroidectomy group and one (4%) in the thyroidectomy group no longer required the administration of insulin.

Discussion

Several authors have noted an increased prevalence of diabetes among patients with hyperparathyroidism relative to that in the general population.[3–5] As pointed out by Ljunghall et al.,[4] this apparently increased prevalence may simply reflect a Berkson bias (*i.e.*, patients with diabetes are more likely to undergo routine biochemical testing than the general population and, thus, they are more likely to be found to have asymptomatic primary hyperparathyroidism).

Several reports have documented increased insulin secretion in response to glucose in patients with hyperparathyroidism.[4,6,7] In a study of nondiabetic patients with primary hyperparathyroidism, Ljunghall et al.[4] demonstrated that this response was diminished after parathyroidectomy. This decreased insulin response could be expected to be associated with a deterioration of glucose tolerance, and some deterioration was in fact found by Ljunghall et al.; however, this was not associated with a change in fasting glucose or hemoglobin A_{1c} levels. Similarly, no improvement was found in the control of diabetes in 36 patients (six requiring insulin) undergoing parathyroidectomy for primary hyperparathyroidism.[4]

Other reports have presented data suggesting that treatment of primary hyperparathyroidism may lead to improved control of diabetes. The reports by Walsh et al.[1] and Akgun and Ertel[2] each include one diabetic patient whose insulin requirement decreased after parathyroidectomy. A second patient reported by Akgun and Ertel[2] demonstrated improvement of an initially impaired glucose tolerance. Encouraged by these case reports, Cheung et al.[3] reviewed their experience with diabetic patients undergoing parathyroidectomy and classified them according to the criteria of the National Diabetes Data Group.[8] Of five patients with type I diabetes, two of the four with secondary hyperparathyroid-

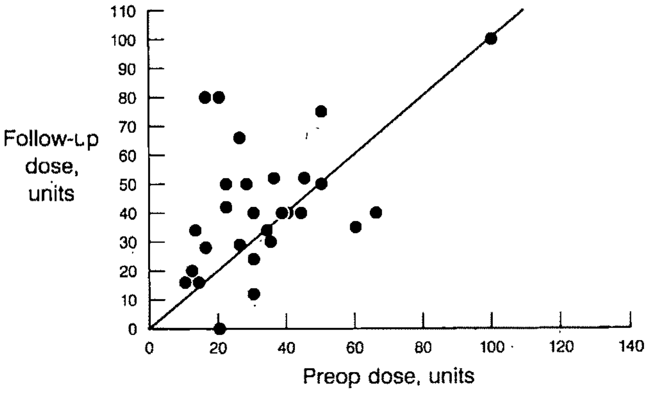

FIG. 4. Relationship of insulin dose at follow-up and preoperative insulin dose for diabetic patients undergoing thyroidectomy. Straight line represents points of no change.

TABLE 3. *Body Weight in 70 Patients with Diabetes Mellitus, by Type of Disease*

	Hyperparathyroidism		Benign Euthyroid Disease		
Time of Determination	No. of Patients	Mean Weight (kg)	No. of Patients	Mean Weight (kg)	P Value
Preoperatively	36	72.9	34	73.5	0.37
At follow-up	30	68.5	26	72.1	0.32
Change	30	−3.4	26	−0.2	0.19

ism and the one patient with primary hyperparathyroidism had decreased insulin requirements after parathyroidectomy. All patients with type II diabetes mellitus described by Cheung et al.[3] had primary hyperparathyroidism. At follow-up of 12 insulin-requiring diabetics with non-insulin-dependent diabetes mellitus, six demonstrated a decreased insulin requirement after parathyroidectomy, five had an increased requirement, and one had no change. Of their patients treated with oral hypoglycemic agents, three improved, nine remained stable, and three eventually required insulin. As they stand, these data do not suggest that parathyroidectomy alters the course of diabetes mellitus. However, Cheung et al.[3] pointed out that 27% of their patients did improve. They suggested that improvement in such a percentage is in marked contrast to the natural history of diabetes mellitus.[3]

By comparing the course of a group of diabetics undergoing parathyroidectomy with that of an appropriate control group, we hope to shed further light on the issue. In this retrospective review, we presented a series of consecutive insulin-requiring diabetics who underwent parathyroidectomy for primary hyperparathyroidism. We also presented a control group comprised of a contemporary series of consecutive insulin-requiring diabetics undergoing thyroidectomy for benign euthyroid disease. The two groups were similar with respect to age and sex distribution, duration of diabetes mellitus, and duration of insulin therapy.

On average, insulin dosages increased in both groups from the preoperative state to follow-up. The increase in insulin dosage was of a lesser magnitude for patients undergoing parathyroidectomy than for those undergoing thyroidectomy. However, the difference (an increase of 7.5 units more for the thyroidectomy group) was not statistically significant. At least 100 patients would be required in each group to identify the significance of this difference with 80% confidence. Our data allow us to state with 95% confidence that any relative decrease in insulin requirement incurred by parathyroidectomy would be less than 19.5 units/24 hours at approximately 6 years of follow-up. Also, our data do not exclude the possibility that parathyroidectomy may even be associated with a slight relative increase in insulin requirements. Note that only two patients in the parathyroidectomy group (and one in the thyroidectomy group) were rendered free of exogenous insulin at follow-up. It thus seems unlikely that parathyroidectomy is associated with dramatic changes in the insulin requirements of diabetics with primary hyperparathyroidism.

A decrease in insulin requirements induced by parathyroidectomy could have been masked by a disproportionate gain in body weight by the parathyroidectomy group. However, the two groups did not differ significantly in regard to preoperative body weight, body weight at follow-up, or change in body weight. Although previous reports have cautioned that diabetic patients with primary hyperparathyroidism undergoing parathyroidectomy may be particularly prone to postoperative hypoglycemia,[2,3] we found this complication in only one of 36 patients.

We were unable to demonstrate that parathyroidectomy leads to a significant reduction in insulin requirements of type II diabetics with primary hyperparathyroidism. Our data do not allow us to reach a conclusion regarding type I diabetics. However, on the basis of existing data, coexistent type II diabetes mellitus should not be considered a further indication for parathyroidectomy in patients with primary hyperparathyroidism.

Assessment of the Use of Transfusion Therapy Perioperatively in Patients with Sickle Cell Hemoglobinopathies

ROBERT J. BISCHOFF, M.D.,* ADRIAN WILLIAMSON III, M.D.,† MICHAEL J. DALALI, B.S.,‡
JANET C. RICE, PH.D.,§ and MORRIS D. KERSTEIN, M.D.‖

During the period of 1978 to 1986, 66 patients (31 men, 35 women) with a mean age of 28.4 years and various sickle cell hemoglobinopathies underwent 82 surgical procedures; 28 were emergencies. Fifty of the 66 patients had HbSS, 13/66 had HbSC, and 3/66 had HbS-thalassemia. All 66 patients received transfusions, although not for all procedures. In 48 patients, transfusion therapy was only administered preoperatively. Simple transfusions (1 to 10 units) were administered in 31 of 48 procedures. Exchange transfusions (1 to 6 units) were performed in nine of 48 procedures. Preoperative hematocrit ranged from 7.0% to 54.2%; of those receiving transfusions the hematocrit ranged from 22.6% to 53.7%. Intraoperative transfusions (1 to 10 units) were performed in 14 of 82 procedures; postoperative transfusions (1 to 6 units) were performed in 13 of 82 procedures. No advantage was noted in preoperative exchange transfusion as measured by a decrease in postoperative complications; a slight increase was seen in atelectasis in this group of patients with preoperative transfusions. An increase was reported in the complication rate of patients with an hematocrit of <30%. The type of transfusion (preoperative, intraoperative, or postoperative) administered did not appear to be related to postoperative morbidity rates. The complication rate for simple transfusions was 51.6% and for multiple transfusions, 55.6%. HbSS hemoglobinopathy had the higher complication rate. The hepatitis B surface antigen was demonstrated in four of 66 (6.1%) patients; ten of 66 (15.2%) developed alloantibodies. The benefits of transfusion therapy should be judged according to clinical needs; not all sickle cell patients need exchange or preoperative transfusion.

From Tulane University School of Medicine and Tulane University School of Public Health and Tropical Medicine, New Orleans, Louisiana

THE USE of blood transfusion therapy in patients with sickle cell hemoglobinopathies either before or after surgery remains a controversial issue. Sickle cell anemia patients are regarded as being at increased risk for surgery. Slight decreases in pH, partial pressure of oxygen (PO_2), blood flow, blood volume, and temperature that occur during surgery may cause a distortion of the biconcavity of these patients' red blood cells into an elongated sickle cell because of the high content of hemoglobin S (HbS).[1] A reduction of blood flow within the capillaries occurs, resulting in further deoxygenation and lowering of the pH. This may eventually lead to a vaso-occlusive crisis with ischemic infarction of the involved tissues resulting in abdominal and skeletal pain, splenic infarction in young children, necrosis of bone marrow, pulmonary infarction, cerebral infarction, hematuria, priapism, or hemolysis.[1] Thus, adequate hydration and oxygenation, as well as avoidance of acidosis and prolonged blood stasis, are thought to be mandatory in the preoperative management of sickle cell anemia patients.

Many authors[2-10] believe that adequate preoperative preparation also requires transfusion therapy to reduce the relative amount of HbS available for sickling and increase the oxygen-carrying capacity of the blood. Janik and Seeler[10] have demonstrated the safety with which such procedures can be performed. In their study, 35 children with HbSS, HbSC, or HbS-thalassemia disease underwent 46 operations without significant mortality rates after having received preoperative transfusion therapy.

Nevertheless, many researchers[11] believe that careful attention to preoperative management and anesthetic

technique may be more important than any type of transfusion therapy in sickle cell patients. Some reports[12] state that preoperative transfusion therapy has been associated with a higher postoperative complication rate than in patients not receiving transfusions. The purpose of this study was to review the perioperative experience with sickle cell patients and evaluate elective transfusion therapy over standard care.

Materials and Methods

Between March 1978 and March 1986, 66 Black patients with various sickle cell hemoglobinopathies underwent a total of 82 surgical procedures at the Tulane Medical Center Hospital and Charity Hospital of Louisiana at New Orleans (Table 1). Twenty-eight of these procedures were emergencies and the remaining 54 were elective. Fifty of the 66 patients had HbSS, 13 of 66 had HbSC, and three of 66 had HbS-thalassemia. The patient ages ranged from 1 to 44 years (mean: 28.4 years), and hospital stay ranged from 2 to 44 days (mean: 23.6 days). Of the 66 patients in this study, 31 were men and 35 were women. Preoperative transfusion therapy (either single or exchange) was performed in all 66 of the patients, although not in all procedures. In only 48 patients, transfusion was given preoperatively and at no other time. Simple transfusions were administered in 31 of 48 procedures, with the amount of blood given ranging from 1 to 10 units. Exchange transfusions (ranging from 1 to 6 units) were performed in nine of 48 procedures, and both simple and exchange were performed in the remaining eight. Preoperative hematocrits upon admission ranged from 7.0% to 54.2%, and the hematocrits in those receiving transfusions before surgery ranged from 22.6% to 53.7%. A preoperative hematocrit of at least 36.0% occurred in 15 of the procedures.

No transfusions were given preoperatively in 16 of the procedures. Five of the 16 patients eventually received either an intraoperative or postoperative transfusion, but the remaining 11 patients did not receive a transfusion at any time during their hospital stay. The patient charts indicate that in all 11 of the procedures the patients received the standard preoperative care given to those with sickle cell hemoglobinopathies. They were adequately supported with intravenous (I.V.) fluids and were kept well-oxygenated both preoperatively and intraoperatively. Body temperature preoperatively was maintained at a level of 35.8 C to 38.0 C. No statistical difference was noted, however, in the amount of standard preoperative care received by the group that received transfusions and the group that did not.

The types of anesthesia administered varied and consisted of such agents as halothane, sublimaze, epidural (marcaine), ethrane, nitrous oxide, fentanyl, forane, pentathane, and local (xylocaine).

TABLE 1. *Surgical Procedures in Sickle Cell Patients, 1978–1986*

Surgical Procedures	Elective	Emergency
Umbilical herniorrhaphy	5	0
Cholecystectomy	11	9
Dilation and curretage	3	3
Tubal ligation	6	0
Hysterectomy	2	0
Skin flap	3	0
Splenectomy	3	5
Tonsillectomy	6	0
Appendectomy	0	3
Open reduction and internal fixation of hip and ankle	0	2
Mastectomy	1	0
Penile revascularization	9	0
Cesarean section	2	3
Vitrectomy	0	2
Cervical lymph node biopsy	1	0
Arteriovenous fistula repair	1	0
Exploratory laparotomy (left ovarian vein thrombosis)	0	1
Warren shunt	1	0
Totals	54	28

Intraoperative transfusions (ranging from 1 to 10 units) were performed in 14 of 82 surgical procedures. Three of the 14 patients were administered blood intraoperatively only. Postanesthesia recovery consisted of maintaining adequate hydration and body temperature. Most patients received short-term oxygen therapy in the immediate postoperative period. Postoperative transfusions (ranging from 1 to 6 units) were performed in 13 of 82 procedures, with two of 13 receiving blood postoperatively only.

The following perioperative complications were evaluated in all 82 surgical procedures: transfusion reaction, fever (secondary to atelectasis, urinary tract infection, thrombophlebitis, wound infection, antibiotics, *etc.*), sickle cell pain and hemolytic crises, volume overload, dehydration, pulmonary embolism, and jaundice. Long-term complications reviewed were the development of hepatitis or alloantibodies.

Results

Table 2 shows the number of postoperative complications encountered in the following subsets: Group 1 included the patients who received only preoperative transfusion therapy (N = 48); Group 2 included those who received no transfusion therapy (N = 11); Group 3 consisted of those who received a preoperative transfusion plus either an intraoperative or postoperative transfusion (N = 18); and Group 4 consisted of those who received either an intraoperative or postoperative transfusion, but not a preoperative transfusion (N = 5). Log-linear analyses were used to determine the impact of transfusion therapy on the complication rate after

TABLE 2. *Postoperative Complications*

[*] Group 1 = those receiving preoperative transfusions only. Group 2 = those receiving no transfusion. Group 3 = those receiving preoperative transfusion and either an intraoperative or postoperative transfusion. Group 4 = those receiving intraoperative or postoperative transfusion, but no preoperative transfusion.

[†] Number of procedures (total 82).

[‡] Includes patients with unexplained fever, upper respiratory tract infections, left lower lobe pneumonia, endometritis, and seizures.

controlling for other variables. In comparing the number of postoperative complications in Group 1 with Group 2, it can be seen by way of percentages that the patients in Group 1 fared no better than those in Group 2, and in some cases worse. In fact, a statistically significant difference ($p < 0.001$) was noted between the amount of postoperative atelectasis experienced by the patients in Group 1 and those in Group 2. It would appear that those receiving transfusion therapy were at a higher risk of developing postoperative atelectasis than those who received no transfusion therapy. Group 3 patients also appeared to have a high complication rate; however, when comparing the complication rate of all four groups, no statistically significant difference was found.

A relationship was found between the immediate preoperative hematocrit and postoperative complication rate. A statistically significant difference ($p < 0.08$) was noted in the complication rate experienced by the patients with a preoperative hematocrit of $<30.0\%$, those with a preoperative hematocrit of 30.0–35.9%, and those with a preoperative hematocrit of $>36.0\%$. Thus, it would appear that sickle cell patients entering surgery with a hematocrit of at least 36.0% have a lower incidence of morbidity than those under this level. The effect of the preoperative white blood cell (WBC) count on postoperative morbidity rate was also analyzed. Using 15.0 as a normal WBC count in sickle cell patients,[13] no significant difference was found in the complication rate between those with a preoperative WBC count of >15.0 and those with a WBC count of <15.0.

The type of transfusion administered did not appear to be related to postoperative morbidity rate. The complication rate in patients receiving simple transfusions was 51.6%, whereas those receiving exchange transfusions had a complication rate of 55.6%. No statistical difference was encountered in any of the postoperative complications between the patients who received simple and those who received exchange transfusions.

When the effect of the type of hemoglobinopathy on the postoperative complication rate was analyzed comparing the postoperative morbidity rate of those patients with HbSS *versus* those with either HbSC or HbS-thalassemia without taking transfusion therapy into account, it was found that the HbSS patients had a significantly higher ($p < 0.05$) complication rate. Of the HbSS patients who had a complication, however, 88% had also received a preoperative transfusion, whereas only 66.7% of those with HbSC or HbS-thalassemia who had also received transfusion had complications. Interestingly, nine of 11 patient-procedures who received no transfusion therapy were either HbSC or HbS-thalassemia. In this group of 11 patients, no difference was noted in the postoperative complication rate among the HbSS patients or those with HbSC or HbS-thalassemia.

The surgical procedures listed in Table 1 were classified as either emergency or elective. Without taking transfusion therapy into account, it was found that the postoperative complication rate for the patients undergoing elective or emergency surgery was similar. Including the administration of transfusions with this analysis, no relationship was found between the type of admission and postoperative morbidity rate. The hepatitis B surface antigen was identified in four of 66 patients, and ten of 66 patients developed alloantibodies.

Discussion

The perioperative morbidity and mortality rates in patients with major sickle cell hemoglobinopathies is known to be significant. Flye and Silver[7] reported a serious complication rate of approximately 50%, which included pneumonia, fever >103 F, and sickle cell crises. Ariyan et al.[6] found the collective postcholecystectomy morbidity rate to be 34%, with pulmonary complications being the most common. A study by Spiegelman and Warden[2] reported a 25% incidence of postoperative complications in 12 sickle cell children who underwent 29 surgical procedures. Three of the patients suffered from subsequent atelectasis and pneumonia: two with wound infections, one from a postoperative crisis, and one with a subhepatic hematoma.

As a result of these complications, strict perioperative management is thought to be essential in sickle cell patients. Sufficient preoperative hydration serves to decrease blood viscosity and microvascular sludging. Hypothermia can be avoided by keeping the patient under blankets throughout the perioperative period. The anesthesiologist must ensure proper oxygenation of the patient before induction of general anesthesia. Arterial blood gases should also be monitored because hypoxia and acidosis may precipitate vaso-occlusive crises. Holzmann et al.[3] concluded in their study that it was not the type of anesthetic agent used that was important, but the avoidance of hypoxemia, acidosis, hypotension, hypovolemia, and hypothermia that was critical.

Lessins et al.[14] showed that *in vitro* filterability of blood is almost normal when a cell mixture contains <40% sickle cells and clinically vaso-occlusive crises occur only when the level of HbS exceeds 50%. Hence, this is the rationale many researchers have been using for performing preoperative transfusion therapy in sickle cell patients. Janik and Seeler[10] stated that they propose a preoperative transfusion of 15–20 mL of packed erythrocytes per kilogram of body weight to a hematocrit of 36% in children with sickle cell hemoglobinopathies. Simple transfusions are advocated by almost all investigators when sickle cell patients have low hemoglobin levels preoperatively, and this technique has been successful in raising the hematocrit and HbA levels while at the same time diluting out the HbS. The oxygen-carrying capacity of the blood is increased as well. Such transfusions also suppress the generation of sickle cell by the bone marrow if performed several days before surgery.[15] The inherent disadvantages of this particular technique are the possibility of prolonged marrow suppression leading to an aplastic crisis and a theoretic increase in the blood viscosity that may precipitate a crisis.[15] Anderson et al.,[16] however, have shown that the addition of normal erythrocytes to sickle cells does not increase the viscosity, and may even decrease it. Simple transfusions may also impose volume overload and the risk of congestive heart failure.[17] Our data show that although there may be some benefit in raising a patient's hematocrit preoperatively, if it is excessively low, the risks of performing such a transfusion appear to outweigh the benefits in any other situation.

Lanzkowsky et al.[17] advocated volume exchange transfusion in preparing the patient for surgery. This technique involves transfusing 15 mL/kg of packed erythrocytes into an antecubital vein while simultaneously removing 20 mL/kg of whole blood by gravity from the opposite antecubital vein. They believe the advantages of this procedure include the rapid removal of sickle cells from the circulation, reduction of blood viscosity, no volume overload, and prevention of hemosiderosis resulting from repeated transfusions. They also believe exchange transfusions in refractory painful crises of sickle cell anemia assist in removing activated procoagulants, retard the formation of excessive thrombin, and thereby help restore normal circulation by decreasing relative resistance. The use of exchange transfusions has been shown to be clearly indicated in patients with sickle cell disease in cases of acute priapism, in the acute chest syndrome with hypoxia, in the scleral buckling procedure for retinal detachment, and before cardiopulmonary angiography (hypertonic dye may cause sudden localized retrovascular sickling).[18] It is also believed[19] that exchange transfusions in patients with overwhelming infection may provide immunologic components at the site of infection, remove bacteria and endotoxins, and improve splenic function by improving the microcirculation. This technique is time-consuming, and blood administration and withdrawal in the small child can be a difficult procedure. Although whole blood exchange transfusions have been shown to be effective by several other investigators,[20–23] our data indicate no advantage of exchange transfusions over single transfusions, or even over those patients who did not receive any transfusion therapy.

Some disadvantages of both simple and exchange transfusions inherent to transfusions themselves are hepatitis, transfusion reactions, development of atypical antibodies, and acquired immune deficiency syndrome (AIDS). Fullerton et al.[24] stated the risk of hepatitis is minimal. In their study group of 260 patients exposed to over 5000 transfusions, only one patient demonstrated a positive hepatitis B surface antigen and six were positive for HbS antibodies. Irregular alloantibodies were found in 7.9%, but only 1.8% had antibodies to more than one red cell antigen. Our study showed four of 66 (6.1%) patients demonstrated the hepatitis B surface antigen, whereas ten of 66 (15.2%) developed alloantibodies. No patient to date has developed AIDS. These data imply considerable risk-morbidity rates as a result of blood transfusions to the sickle cell patient.

Morrison et al.[25] stated that to lower the incidence of hepatitis even further, the donor blood should be proved to be Australia antigen negative and obtained from a family member or friend who has never had a history of liver diseases. The use of buffy coat poor washed red cells should reduce the incidence of reactions to white cell antigens, as well as dilute the hepatitis virus if present.

Curran et al.[26] provided substantial evidence that transfusion-related AIDS does occur. Although this is currently an extremely infrequent complication of blood transfusion, physicians must weigh the risk of transfusion against the expected benefit. Ellison and Ferrara[15] stated that in the absence of symptomatic anemia, the benefits of preoperative transfusions do not uniformly outweigh the risks outlined above. Our study supports this belief and it appears that the benefits of transfusion should be judged according to the clinical situation.

Management of Severe Caustic Stenosis of the Hypopharynx and Esophagus by Ileocolic Transposition *Via* Suprahyoid or Transepiglottic Approach

Analysis of 18 Cases

Eighteen cases of severe chronic caustic stenosis of the hypopharynx and esophagus are presented. Restoration of digestive continuity was accomplished by retrosternal ileocolic transposition. The cervical approach and the position of anastomosis depended on the status of the hypopharynx. When one pyriform sinus remained open (type I, N = 4), an anterior suprahyoid approach was used in conjunction with lateral hypopharyngotomy because it facilitated the anastomosis and additional minor surgical procedures. When the hypopharynx was completely stenosed (type II, N = 14), a transepiglottic approach consisting of partial horizontal laryngectomy was used because it allowed excision of the supraglottic stricture, restoration of the oropharyngeal cavity, anastomosis to the posterior oropharyngeal wall, management of an eventual laryngotracheal stenosis, and elevation of the laryngeal inlet above the digestive anastomosis. After operation, several endoscopic examinations were required, sometimes combined with reoperation. Return of deglutition assuring normal nutrition was obtained in 61% of patients: 3 of 4 type I and in 8 of 14 type II.

MASSIVE INGESTION of a corrosive agent usually results in a life-threatening clinical condition that requires emergency intensive care often combined with surgical intervention.[1–4] If the esophagus has been removed in the initial emergency or progressively stenosed as a result of the caustic burn,[5,6] reconstructive surgery is frequently required to restore digestive continuity. The concomitant development of severe hypopharyngeal stricture is an infrequent yet critical complication, occurring in one of 145 patients (0.7%) in the study of Cardona and Daly,[7] and in one of 16 patients (6%) in Schild's study.[8] As pointed out by Gupta,[9] such an association raises a major problem in that: (1) the upper anastomosis of the digestive graft used to bypass the stenotic area is located at the level of the laryngeal inlet, and (2) fibrosis of the pharyngeal wall affects its capacity to propel the bolus through the anastomosis in the first voluntary stage of deglutition. Thus, restoration of digestive continuity in this area interferes with the mechanisms of deglutition and respiration.

In the literature, some studies have described the epidemiologic[7,8,10] and endoscopic[8,10,11] aspects of such lesions and highlighted the controversies and difficulties in their medical[7,8,10,12] and surgical[13–18] management. The bypass procedure adopted have consisted of transposition of the stomach,[9,16] of the right[13,14,16,17] or transverse[13,14,17] colon, or of a free jejunum graft.[16] The pharynx was entered anteriorly,[13,14] laterally,[13–18] or posteriorly.[9,16] Resection of scar tissues was followed by Z-plasties[15,19] and/or covering the raw area with skin or dermal graft,[14,15] or local or regional mucosal or skin flaps.[17] However, the limited number of cases reported in most of these studies makes it difficult to evaluate and compare the functional benefit of the various procedures described.

At the Paris poison center between 1978 and 1986, 11 of 528 patients (2.1%) admitted for caustic ingestion burns developed combined hypopharyngoesophageal strictures requiring surgical treatment. Seven additional patients were referred from other centers for reconstruction. This paper: (1) reports the clinical features and results of these 18 cases; (2) describes the technique we have developed with special emphasis on the anterior cervical approach either suprahyoid or transepiglottic; and (3) emphasizes the role of the laryngologist, especially in the clinical assessment of the lesions and in postoperative management.

Patients and Methods

Table 1 summarizes the main clinical features of the 18 patients.

TABLE 1. *Clinical Features of the 18 Patients*

Case No.	Sex, Age, Cause	Emergency Treatment	Year of Reconstruction	Type of Digestive Lesions, Associated Lesions	Delay	Approach of the Pharynx	Secondary Operations	Functional Results
1	M, 30 yrs, suicide	IC, jejunostomy, jejunostomy, tracheostomy	1978	II	2 yrs	Lateral pharyngotomy	Cervical enterotomy (×2)	Failure
2	F, 24 yrs, accident	IC, gastrostomy	1978	II, laryngotracheal stenosis	9 yrs	Transepiglottic	Cervical enterotomy	Satisfactory
3	F, 57 yrs, suicide	IC, tracheostomy	1979	I	6 mths	Lateral pharyngotomy + suprahyoid	Cervical enterotomy, new ileopharyngoplasty	Poor
4	M, 36 yrs, suicide	IC	1979	II	2 yrs	Lateral pharyngotomy	Pharyngoplasty with D.P. flap	Poor
5	F, 28 yrs, suicide	IC, surgery, tracheostomy	1979	II	4 mths	Lateral pharyngotomy	Pharyngoplasty with D.P. flap	Satisfactory
6	F, 48 yrs, accident	IC, gastrostomy	1980	I	28 yrs	Suprahyoid		Satisfactory
7	F, 44 yrs, suicide	IC, surgery	1980	I	5 mths	Suprahyoid	New ileopharyngoplasty	Satisfactory
8	F, 44 yrs, suicide	IC, surgery	1981	II	4 mths	Transepiglottic		Satisfactory
9	F, 58 yrs, suicide	IC	1982	I, laryngotracheal stenosis	5 mths	Suprahyoid	New ileopharyngoplasty	Satisfactory
10	M, 58 yrs, suicide	IC, surgery	1982	II	5 mths	Transepiglottic	Cervical enterotomy	Satisfactory
11	F, 25 yrs, suicide	IC	1982	II	6 mths	Transepiglottic		Satisfactory
12	M, 21 yrs, suicide	IC	1984	II	8 mths	Transepiglottic	Cervical enterotomy, new ileopharyngoplasty	Poor
13	F, 31 yrs, suicide	IC	1984	II	5 mths	Transepiglottic	New ileopharyngoplasty	Satisfactory
14	F, 19 yrs, suicide	IC, surgery, tracheostomy	1984	II, laryngotracheal stenosis	1 yr	Transepiglottic		Poor
15	F, 15 yrs, suicide	IC, surgery, tracheostomy	1985	II	4 mths	Transepiglottic		Satisfactory
16	M, 23 yrs, accident	IC, surgery, tracheostomy	1985	II	4 mths	Transepiglottic	Cervical enterotomy	Failure
17	F, 29 yrs, suicide	IC, surgery, tracheostomy	1986	II	7 mths	Transepiglottic	Cervical enterotomy	Satisfactory
18	F, 46 yrs, suicide	IC, surgery, tracheostomy	1986	II	9 mths	Transepiglottic	Excision of ileocolic graft	Failure

Age and Sex Distribution

Age ranged from 15 to 58 years with an average of 35 years. Five patients were men, 13 were women.

Causes and Ingested Products

In 16 cases, ingestion took place in suicide attempts. This occurred in two schizophrenic patients and in nine patients with depressive, compulsive, and aggressive personality patterns. In five cases, no psychological evaluation was made because of linguistic problems. In two cases, ingestion was accidental.

The responsible agents were always household products, sold in France, with no restriction and with insufficient instructions for use. In 17 of the 18 cases, it was a strong base, highly concentrated sodium hydroxide added to a nonionic surface-active agent, in liquid or crystal form. In one case, it was nitric acid. The approximate volume ingested ranged from 50 to 400 ml.

Initial Treatment

All patients were initially treated as severe burns in an intensive care unit. In 12 cases, emergency surgery was performed based on previously published criteria.[1,4] Surgery consisted of laparotomy and feeding jejunostomy or gastrostomy in three cases, and gastrectomy with transhiatal blunt esophagectomy by stripping, feeding lateral jejunostomy, and cervical esophagostomy[4] in nine cases. Two of these 9 patients had a tracheobronchial necrosis due to aspiration of the corrosive agent or to extension of the necrotic process from the esophagus to the trachea. This was treated by thoracotomy, patching of the back wall of the trachea with pulmonary apposition, and temporary tracheostomy. In four of the 12 surgical patients and in one nonsurgical patient, tracheostomy was also performed because of acute supraglottic edema. This tracheostomy was maintained until the time of reconstructive surgery.

Chronic Caustic Lesions

Corrosive injuries of the upper digestive tract and the classification adopted are described in detail in the section on endoscopic evaluation. In the 18 cases considered, chronic caustic lesions involved mild burns of the buccal or oropharyngeal cavity, major stenosis of the hypopharynx with supraglottic stricture and, in the nine cases without emergency esophagectomy, complete obliteration of the esophagus. According to our classification, four patients were considered type I, and 14 were considered type II.

They were three cases of major laryngotracheal lesions: (1) two cases of incomplete laryngotracheal stenosis that were treated by the standard laryngofissure procedure, 2 years before reconstructive surgery in one case and 1.5 years after surgery in the other case; (2) one complete stenosis of the larynx that required a total laryngectomy 2 years after the ingestion and 6 months before reconstructive surgery.

Delay between Ingestion and Reconstructive Surgery

The interval from caustic ingestion to reconstructive surgery ranged from 4 months to 28 years.

Types of Reconstructive Surgery

In all instances, re-establishment of digestive continuity was achieved by retrosternal transposition of the right ileocolon, except in one case where the transverse colon was used. The oropharyngeal approach was accomplished by: (1) lateral pharyngotomy in four cases; (2) anterior suprahyoid pharyngotomy in four cases; (3) anterior epiglottectomy (transepiglottic approach) in 11 cases.

Intra- and Postoperative Complications

Necrosis of the ileocolon occurred at the 13th postoperative day in one patient requiring emergency excision of the digestive graft. Four pneumothoraces occurred during construction of retrosternal tunnels. They were complicated by empyema in two cases, but all resolved without sequelae. Four cervical and one abdominal fistulae occurred at the level of the digestive anastomosis and healed in a few days. One case of phlebitis of the left arm resolved with treatment. There was no surgical mortality.

Results

The first postoperative endoscopy was performed between weeks 1 and 2 after surgery. In two cases, the site of anastomosis could not be found, probably because of the extreme evolutivity of the stenotic process. In these two cases, new operations were performed a few months later but the final results were failures. In one other case, necrosis of the ileum was observed which required immediate excision of the graft. No further attempt at reconstruction was made. In the 15 remaining cases, endoscopic sessions were performed each week during the first month, every 2–3 weeks the following months, and then as needed. In 10 of these 15 cases, one or several operations were required. They consisted of retrograde digital dilation by cervical enterotomy in 6 cases, new ileopharyngoplasty in five cases, and new pharyngoplasty by means of a deltopectoral flap in two cases.

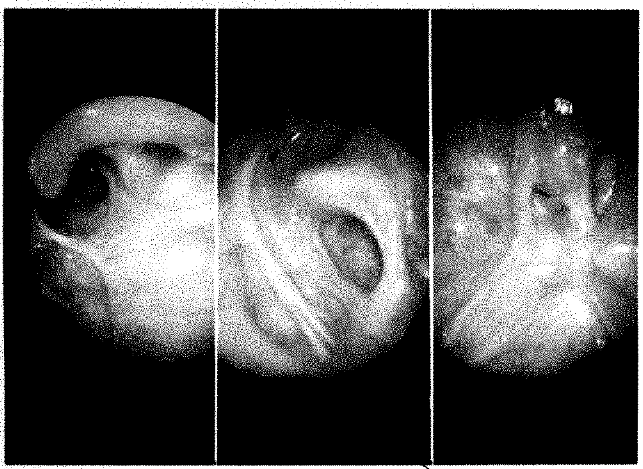
From a functional point of view, results were not assessed before the 6th postoperative month. The criteria of success were exclusive oral alimentation of both liquids and solids, stable body weight, no more than two endoscopic dilations per year, and good phonatory function. Accordingly, our results can be analysed as follows: (1) three cases were failures, in one case because of necrosis of the ileocolic graft and in two cases because of persistent restricturing of the corrosive lesions. Despite new operations, patent anastomoses could not be obtained. Moreover, these two highly disturbed patients refused any care, including attempting to smallow, and died of severe malnutrition. (2) In four cases, results were poor. Despite repeated endocopic dilations and/or repeat surgery, severe dysphagia persisted. These patients continue to be fed by jejunostomy and still have tracheostomy. (3) The 11 remaining patients had satisfactory results with follow-up ranging from 1.5 to 8 years. This was obtained without further endoscopic dilation in two cases, with one or two endoscopic dilations per year in three cases, and with reoperation followed by annual or biannual endoscopic dilations in six cases. Barrium swallow x-ray studies confirmed the subjective appraisal of deglutition.

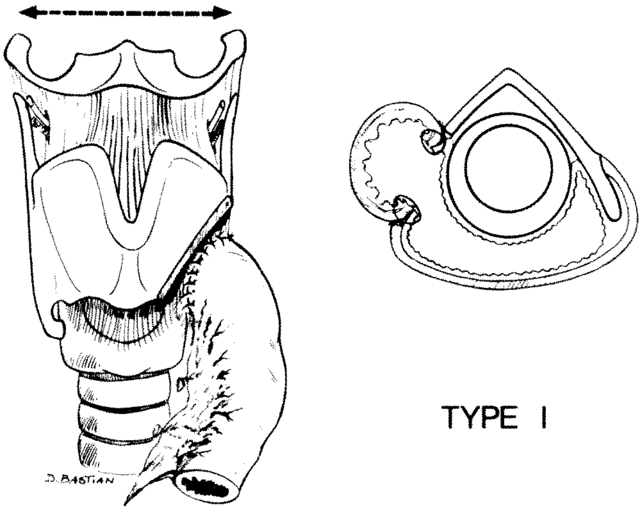
Thus, functional results were satisfactory in three of four type I lesions, and in eight of 14 type II lesions.

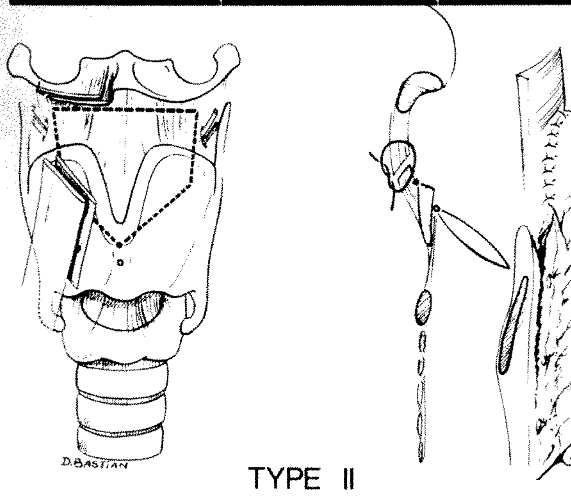
Discussion

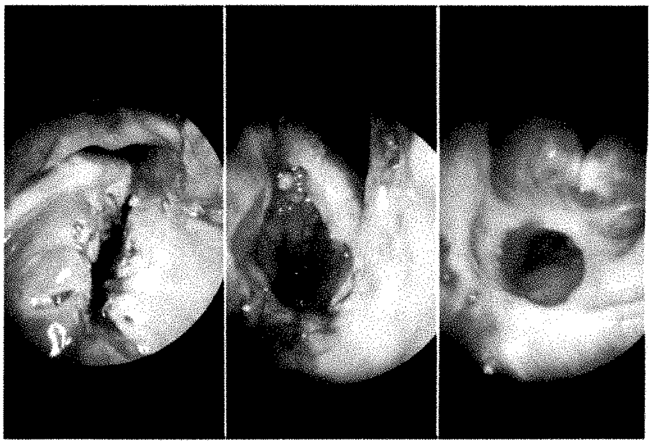
The main surgical problem raised by the combined hypopharyngeal and esophageal stenosis is that restoration of digestive continuity interferes with the processes of deglutition and respiration. In light of the results obtained in 18 cases, we report the problems encountered and the surgical technique progressively developed.

The initial assessment of the upper digestive tract and the laryngeal airway is usually performed 1 month after the caustic ingestion, once the critical stage has passed and if reconstructive surgery is considered. It is repeated every month during the stage of active stricture formation and until relative stabilization has occurred. Assessment consists of examination of the buccal cavity looking for retractile scars of the lips, vestibule, floor of the mouth, cheeks, and frenulum as well as assessing the mobility of the tongue, digital palpation of the base of the tongue looking for fibrous infiltration of the muscular bulk, and endoscopy conducted under neuroleptanalgesia or general anesthesia. In the latter case, tracheostomy, if not already performed, may be necessary due to the narrowness of the airway that is often encumbered









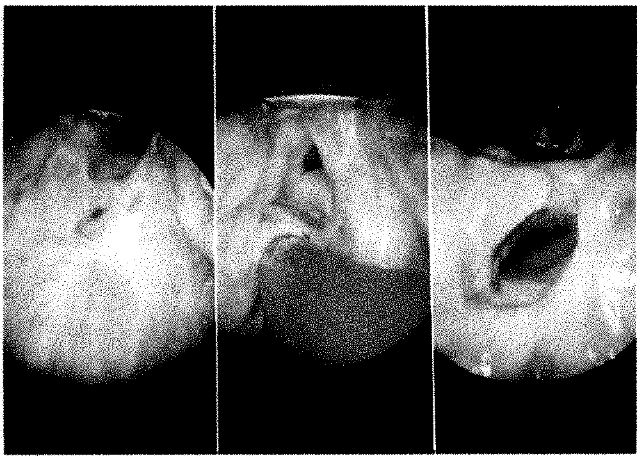


FIG. 1. (*Top left*). Endoscopic classification of the lesions. *Left:* Type I. The left pyriform sinus remains open. Note webs on the posterior wall and adhesion of the arytenoids to the hypopharynx. *Middle:* Type II. Epiglottis is reduced to a suprahyoid stump. The two pyriform sinuses are closed. A narrow laryngeal airway persists. *Right:* Type II. Complete fusion of the epiglottis to the oropharyngeal wall, requiring a tracheostomy. The 2 pyriform sinuses are closed. FIG. 2. (*Top right*). Schematic representation of the surgical procedures used in Type I lesions. FIG. 3. (*Middle left*). Schematic representation of the surgical procedures used in Type II lesions. Note that after resection of the upper part of the thyroid cartilage, the laryngeal inlet is pulled up. FIG. 4. (*Middle right*). Postoperative endoscopic examination. *Left:* at the 14th postoperative day, sutures are still visible. *Middle:* after 1 month. Note the granulation tissue at the anterior part of the anastomosis. *Right:* after 6 months. Note the darker aspect of the ileal mucosa. FIG. 5. (*Bottom left*). Endoscopic management of a stenosis recurring 2 years after reconstructive surgery. *Left:* before dilation. *Middle:* a 28 French bougie is introduced through the stenosis under neuroleptanalgesia. *Right:* result 1 month after 2 sessions of bougienage.

by saliva. In contrast to acute phase management, assessment of chronic injuries is achieved better by a rigid tube than by a flexible fiberoptic examination, because the open hypopharyngoscope provides the endoscopist with the sensitive perception of tissue resistance[13] and facilitates removal of granulation tissues, infiltration of steroids, section of webs, etc.

Although contrast radiography is of no value in assessing the digestive tract, radiologic evaluation may be necessary to evaluate the subglottic or tracheal area. Retrograde fibroscopy *via* tracheostomy is well suited to examination of these regions. The lesions found are generally fairly stereotyped and, from a surgical point of view, may be classified into 2 types (Fig. 1). In type I, the oropharynx may have some stricture but the valleculae are usually preserved. The epiglottis is only partially fused to the lateral wall of the pharynx, and the hypopharynx is incompletely stenosed with one of the two pyriform sinuses remaining open. However, a small bougie introduced into the lumen indicates complete obliteration of the cricopharyngeal sphincter. In type II, the oropharynx contains several fibrous webs and is markedly shrunken with fusion of the base of the tongue to the posterior and lateral walls and disappearance of the valleculae. The epiglottis is unrecognizable, reduced to a suprahyoid stump, and completely or incompletely scarred into the hypopharynx. In this latter case, a passage may persist at the junction of the oropharynx and hypopharynx, behind the epiglottic remnant. Through this small orifice, the laryngeal vestibule may be seen. It is often preserved, but the mobility of the vocal cords is reduced by the fusion of the two arytenoid folds to the posterior wall of the hypopharynx. The two pyriform sinuses are completely closed.

These two types, based mainly on the status of the hypopharynx, must be clearly distinguished, for each implies a different management approach. The surgical decision should take into consideration three essential factors:

1. The evolutivity and the extent of the lesions. Ideally, surgery should not be undertaken before the scarring process is completed. In fact, the contracture tendency of corrosive injuries persists indefinitely, decreasing with time but never achieving complete stability. The operation, therefore, must neither be too early (so as to avoid surgery on any actively inflammatory lesions), nor too late (so as to avoid prolonged hospitalization). In our experience, reconstruction is postponed as long as endoscopic examination indicates mucosal erythema, superficial or deep ulcerations, granulation tissue, or whitish membranes. There must be a minimum of 4 months between the time of caustic ingestion and surgery. Absolute contraindications are represented by massive lesions involving the oropharynx and the buccal cavity. Such extensions may cause trismus, complete immobility of the tongue, and severe retraction of the lips which prevent buccal opening and swallowing.

2. Associated laryngotracheal stenosis. These lesions must be treated before or simultaneously with the digestive stenosis. If performed afterward, it may jeopardize the functional result of reconstructive surgery since the mechanism of deglutition, when successfully restored, always remains precarious.

3. Psychological profile. This factor is of major importance because it governs to a large degree the functional result of the operation. The need for active participation of the patient during the long and difficult postoperative period makes precise psychological evaluation indispensable, analysing especially the reasons for the suicide attempt and the patient's will to recover.

The operation is performed by a double surgical team. It begins with a tracheostomy if the patient does not already have one. The abdominal stage consists of retrosternal isoperistaltic transposition of the ileocolon.[20] It is performed first to ensure that the length of the graft is sufficient to reach the cervical area. In our opinion, this technique presents the following advantages over colon or gastric bypass[21]: (1) safety of its blood supply, allowing a long graft to be obtained; (2) ileal diameter adapted to the oropharyngeal receptor; (3) plasticity and size of the digestive graft allowing it to be placed in the prevertebral space and providing a satisfactory cosmetic appearance of the cervical area; and (4) antireflux effect of Bauhin's valve.

The ileocolic graft is thus mobilized, transposed retrosternally, and introduced into the cervical region behind the medial aspect of the left clavicle. As for the burned esophagus, when emergency removal has not been done, we believe that for previously published reasons[1] esophagectomy can frequently be avoided.

The cervical stage is then carried out. It consists of five essential steps:

1. The skin incision should remain separate as far as possible from that of the tracheostomy. This is to minimize the risk of contamination of the ileal graft and mediastinis from an infection complicating the tracheostomy. We usually adopt an inverted, L-shaped incision.

2. The approach to the pharynx depends on the status of the hypopharynx. In type I lesions (Fig. 2), the pharynx is first entered by suprahyoid transvallecular route. Through this opening, a finger is inserted into the free pyriform sinus. After division of the inferior constrictor, the lateral and inferior aspect of the thyroid cartilage is resected, the mucosa of the pyriform sinus is exposed by the surgeon's finger, and a lateral hypopharyngotomy of about 2 cm is made over the tip of the finger. In type II lesions (Fig. 3), the oropharynx is entered by a transepiglottic approach. As in partial horizontal laryngectomy, the infrahyoid muscles are separated about 1 cm below the inferior aspect of the hyoid bone. The thyroid notch is exposed, and after elevation of the perichondrium, a triangle-shaped piece of the upper half of the cartilage is resected. The laryngeal airway is entered just above the anterior commissure. Epiglottectomy is performed, care being taken not to damage the superior laryngeal pedicles and the mucosa of the vestibular folds.

3. The bed for the ileal graft is then prepared. The carotid artery and the jugular vein are exposed and retracted laterally by division of the thyroid vessels. The

omohyoid muscle is divided. The posterior wall of the pharynx is mobilized from the prevertebral wall by gentle finger dissection.

4. The digestive anastomosis is performed, but its location depends on the type of stenosis. In type I, the ileal graft is sutured to the mucosal edges of the hypopharyngostomy exposed by the finger introduced by the suprahyoid aperture. In type II, an elliptical-shaped, vertical incision is made through the posterior wall of the oropharynx, overhanging the interary tenoid space by about 1 cm. The two edges of the incision are then sutured to the ileum placed in the prevertebral space.

5. The closure of the oropharynx is made following the usual technique of partial laryngectomy. No attempt is made to repair the mucosal defect of the pharynx. The mucosa of the vestibular folds is meticulously sutured to the thyroid perichondrium. About 2 cm of the infrahyoid muscles are resected, and the muscles are resutured so that the larynx is pulled up. No nasal feeding tube is placed across the digestive anastomosis.

The two pharyngeal approaches we adopt depending on the condition of the pyriform sinuses present the following advantages. In type I lesions, the suprahyoid approach combined with a lateral hypopharyngotomy allows, without disturbing the function of the laryngeal vestibule, full evaluation of the lesions, minor surgical procedures such as Z-plasties, excision of focal scars, and/or local grafts under direct vision, good exposure of the remaining pyriform sinus by the finger introduced through the suprahyoid aperture, and precise approximation of the mucosal edges to be sutured. In the literature, lateral hypopharyngotomy has been proposed in case of stricture involving the cricopharyngeal area or part of the hypopharynx.[14-18] In our experience, however, this approach used alone in four patients did not provide such a satisfactory surgical exposure, possibly accounting for the poor results obtained in these cases. In type II lesions, the transepiglottic approach we use differs from that described by Ogura et al.[13] for hypopharyngeal repair in that it is performed at the same time as restoration of digestive continuity and consists of a partial horizontal laryngectomy with resection of the upper part of the thyroid cartilage. Such an approach allows precise assessment of the lesions and anastomosis between the ileum and the pharynx under direct visual control, restoration of the oropharyngeal cavity by mucosal relining of the deep face of the infrahyoid muscles, excision of the supraglottic stricture, thus preventing, or at least limiting, recurrence of the adhesion between the epiglottis and the posterior wall of the pharynx, diminution of aspiration, because the upper traction of the remaining larynx elevates the respiratory tract and thus reduces the declivity of the laryngeal inlet as compared to that of the digestive anastomosis, and combined treatment of eventual laryngotracheal stenosis, when necessary.

The first endoscopic examination is performed between the first and second postoperative week. Granulation tissue is frequently found at the level of sutures and raw areas and must be carefully removed. The patency of the anastomosis is verified and steroids (triamcinolone, 40 mg/ml) are infiltrated in all inflammatory zones (Fig. 4). Thereafter, and when no further surgery is planned, tracheostomy is removed and swallowing instructions are begun with progressive return of the diet to normal within 1 month. Aspirations are frequent but gradually decrease as the ability to swallow develops. The jejunostomy should be maintained at least 1 or 2 months after the return of deglutition to ensure that solid and liquid alimentation is satisfactory and provides stable body weight. Regurgitation was not observed in our series, probably because of the antireflux effect of Bauhin's valve.

The importance of the endoscopic management in the final outcome must be stressed for the stenotic process seems particularly active throughout the postoperative period. Consequently, it is essential to repeat endoscopic examination every week during the first month, every 2 or 3 weeks the next 2 months, and then as needed. Finally, the prolonged stricture tendency of the corrosive injuries accounts for the long-term nature of the disease. As a result, some degree of stricture may recur at the pharyngeal site of the anastomosis and does not represent an abnormal feature. The patient should be clearly advised to visit his physician as soon as dysphagia develops or increases. Although mild stenosis of the anastomosis is easily managed by one or two sessions of peroral bougienage (Fig. 5), complete obliteration may require retrograde dilation by cervical enterotomy.

Conclusion

Hypopharyngeal stricture combined with esophageal obliteration makes restoration of digestive continuity difficult because it impedes normal deglutition and respiration. Careful clinical, psychiatric, and endoscopic evaluation is essential in surgical management. The site of the upper digestive anastomosis depends on the type of lesion encountered. When a pyriform sinus remains open (type I lesion), a suprahyoid approach is used in conjunction with lateral hypopharyngotomy to facilitate the anastomosis and additional minor surgical procedures. When the hypopharynx is completely stenosed (type II lesion), a transepiglottic approach is used, which allows excision of the supraglottic stricture, elevation of the laryngeal tract, suture of the digestive graft to the posterior wall of the oropharynx, and treatment of eventual laryngotracheal stenosis. In both cases, the postoperative and follow-up periods are long and difficult, requiring several endoscopic examinations and often, repeated operations.

In the current study, return of deglutition assuring normal nutrition was obtained in 11 of 18 patients (61%). Experimental studies[6,22] in the future may provide insight into the precise mechanisms of stricture subsequent to ingestion of corrosive materials. Such basic knowledge might allow additional prevention and therapeutic measures to add to the present surgical art and improve the prognosis of caustic ingestion.

Endoesophageal Pull Through

A Technique for the Treatment of Cancers of the Cardia and Lower Esophagus

FARROKH SAIDI, M.D., F.A.C.S., F.R.C.S.

From the Department of Surgery, Modarress Hospital, Beheshti (National) University of Medical Sciences, Tehran, Iran

Transthoracic and extrathoracic approaches to cancers of the lower esophagus and cardia each have advantages and drawbacks; the trauma of thoracotomy must be balanced against that of blunt mediastinal extraction of the esophagus. A different surgical approach is proposed in this paper, avoiding both thoracotomy and encroachment upon thoracic mediastinal structures. This technique is based on the removal of the tumor and the esophageal mucosa above it as a distinct anatomic layer by blunt dissection through separate abdominal and neck incisions. This is followed by pulling upward a segment of stomach (or colon) through the esophageal muscular tunnel into the neck for a cervical anastomosis. This endoesophageal pull through (EEPT) approach has been used in the surgical treatment of a total of ten patients, six with adenocarcinomas of the cardia and four with squamous cell carcinomas of the lower esophagus. In nine patients the stomach, and in one patient the left colon, was brought to the neck to reestablish gastrointestinal (GI) continuity. The operation was well tolerated. There was no excessive intraoperative or postoperative bleeding, and there was no in-hospital mortality up to 30 days. The major postoperative complication was cervical anastomotic leakage seen in four patients. The EEPT technique is a palliative approach for cancers of the lower esophagus and cardia, comparing favorably with the standard extrathoracic or transthoracic transhiatal procedures.

THE SURGICAL TREATMENT of cancers of the lower esophagus and cardia consists of resection of the tumor-bearing area followed by reestablishment of gastrointestinal (GI) continuity. The conventional transpleural approach with an intrathoracic esophagogastrostomy has been challenged by the extrathoracic approach with anastomosis performed in the neck.[1-3] Avoidance of thoracotomy is undoubtedly of value in debilitated patients with poor lung function. The hazards of a cervical anastomosis carry a small morbidity rate. There are reservations about a blunt, essentially blind extraction of the intrathoracic esophagus, a procedure believed by some to be inherently less safe than resection under direct vision.[4,5]

A contrasting surgical approach to cancers of the lower esophagus and cardia, an endothoracic endoesophageal pull through (EEPT) technique is now proposed. The tumor and the esophageal mucosa above it are removed by digital dissection, and the esophageal muscular tunnel that remains, its blood supply intact, used as a conduit to bring a segment of the GI tract to the neck for cervical anastomosis. Stripping of the mucosal sleeve is done entirely from within the abdomen and through the neck. A thoracotomy is not necessary, and no extraesophageal mediastinal dissection is done.

Materials and Methods

The initial attempt at esophageal mucosal stripping was carried out on a fresh autopsy specimen. It was found that the normal esophageal mucosa could be readily freed of its submucosal bed and extracted intact almost effortlessly from within its encasing muscular layer.

To test the surgical feasibility of the technique, three successive patients with cancers of the cardia and middle and lower esophagus were first operated on by a conventional transthoracic approach putting to test the concept of esophageal mucosa stripping. Two patients, a 55-year-old male and a 65-year-old female, had cancers of the lower esophagus and cardia, respectively. The third patient, a 65-year-old female who had a distal gastrectomy performed for antral carcinoma 4 years earlier presented a squamous cell cancer of the middle third of the esophagus.

A left posterolateral, thoracoabdominal incision was performed in these three preliminary cases, entering the chest through the sixth interspace. The tumor was re-

TABLE 1. *Clinicopathologic Summary of Patients Treated by the EEPT Technique*

Patient	Age	Sex	Pathology	Organ Used for Reconstruction	Complications; Follow-up Results
A	61	M	Adenocarcinoma of cardia; many involved nodes.	Stomach	Anastomotic leakage, later ceased; died suddenly at home 2.5 months after operation.
B	55	F	Adenocarcinoma of cardia; no grossly involved nodes.	Stomach	No complications; no recurrence at 6 months.
C	54	F	Adenocarcinoma of cardia; no grossly involved nodes.	Stomach	200 mL right pleural effusion; no recurrence at 5.5 months.
D	65	F	Squamous cell carcinoma of lower esophagus.	Stomach	Anastomotic leakage with late stricture; no recurrence at 5 months.
E	52	M	Unresectable adenocarcinoma of cardia; liver metastases.	Stomach	Postoperative atelectasis, left upper lobe; eating, but losing weight.
F	50	F	Squamous cell carcinoma of lower esophagus.	Stomach	Intermittent anastomotic leakage for 3 weeks; no recurrence at 4 months.
G	49	M	Infiltrating carcinoma of stomach, total gastrectomy done.	Left colon	Slightly hoarse, eating well; no recurrence at 4 months.
H	52	M	Squamous cell carcinoma of lower esophagus.	Stomach	No complications; no recurrence at 3.5 months.
I	60	M	Squamous cell carcinoma of lower and middle esophagus.	Stomach	350 mL right pleural effusion; transient cardiac arrest; no recurrence at 3.5 months.
J	55	F	Adenocarcinoma of cardia; preoperative esophageal perforation.	Stomach	Anastomotic leakage; preoperative empyema controlled at 3 weeks.

sectable in all three cases. For the first two patients the distal stomach was mobilized and brought into the left chest, keeping intact the right gastric and right gastroepiploic vessels. For the third patient, because of a previous distal gastrectomy, an isoperistaltic segment of left colon was mobilized using the ascending branch of the left colic artery as the nutrient vessel.

In all of these cases the normal esophageal wall was opened a few centimeters below the level of the aortic arch in a plane between the muscular and mucosal layers. The inner mucosal sleeve was freed along its entire length by digital dissection, working at first from within the chest and next through a separate incision in the neck. It was delivered intact without any excessive bleeding. GI continuity was reestablished by pulling the prepared stomach in two patients and the colon segment in the third under direct vision through the remaining esophageal muscular tunnel into the neck for a cervical anastomosis.

All three patients had a satisfactory postoperative course and were taking liquids and semisolids at the time of discharge 7–10 days postoperatively.

Ten consecutive patients with cancers of the lower esophagus and cardia were then operated upon in a uniform manner, using the EEPT technique without thoracotomy.

Clinical Material

There were five men and five women in this series, whose ages ranged from 49 to 65 years (Table 1). The presenting complaint in nine cases was progressive dysphagia and weight loss. Only one patient had chronic upper abdominal pain. Six patients had adenocarcinoma of the cardia and four had squamous cell carcinoma of the lower esophagus. All patients had a preliminary barium swallow. The diagnosis was established in all cases by endoscopic biopsy, except in the last case where the lower esophagus was perforated during esophagoscopy elsewhere, and the diagnosis made subsequently at laparotomy. Five patients were chronic smokers, but none had any clinically significant pulmonary or cardiac disorders. One patient gave a history of melena requiring blood transfusion a few weeks before admission. This patient had a hemoglobin level of 10 mg/dL; that of the others ranged from 11.5 to 15 mg/dL. No preoperative hyperalimentation was carried out. One patient was found at operation to have a linitis plastica type of gastric tumor involving the whole stomach. In one patient the tumor proved, despite all attempts, to be unresectable; the EEPT procedure was done in both these cases despite these features, wholly as palliation.

Operative Technique

With the patient in the supine position and the head turned to the right, the entire abdomen, anterior chest, and left neck areas are exposed, cleansed and appropriately draped. The left arm in full extension is kept abducted to the side and only the right arm is used for

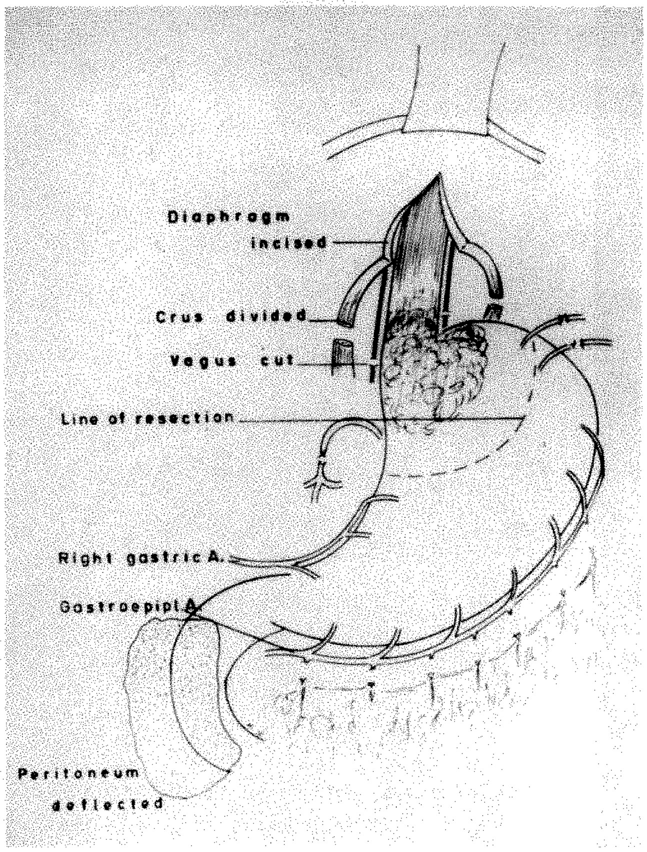

FIG. 1. The entire stomach is first mobilized. Proximally, both crural limbs are divided and that part of the diaphragm arching over the esophagus is incised upwards for about 5 cm to provide maximal exposure of the lower esophagus well above the tumor mass. The vagus nerves are cut. Distally, a generous Kocher maneuver is performed, allowing free upward traction of the stomach and duodenum. The left gastric and short gastric arteries are divided and ligated. The right gastric and gastroepiploic arteries are preserved as nutrient vessels. The line of gastric transection lies about 5–6 cm below the palpable lower margin of the tumor mass.

insertion of arterial and venous lines. A large sized nasogastric tube is passed and kept in place.

The abdomen is first opened through a long midline upper abdominal incision extended to below the umbilicus. After excision of the xyphoid, a fixed sternal retractor is applied to the upper part of the abdominal incision to provide maximum exposure of the lower mediastinum. General abdominal exploration is carried out to determine the extent of the tumor's growth and its resectability, and to establish the presence or absence of metastatic disease.

The esophagogastric junction is exposed after the left lobe of the liver is detached at its triangular ligament from the diaphragm and deflected to the right (Fig. 1). The tendinous portion of the diaphragm arching over the esophagus is incised upwards in the midline until the pericardium is exposed. This opens up the lower mediastinum as viewed from the abdominal side. Even greater access is achieved by transecting the two limbs of the diaphragmatic crus. The two vagus nerves are also cut, allowing further downward traction and better exposure of the esophagus above the tumor itself.

The stomach, along with the tumor mass, is mobilized and separated from the posterior abdominal wall and surrounding structures, taking as many nearby grossly involved nodes as is practicable. The left gastric artery is divided at its origin. The right gastric and gastroepiploic vessels are carefully preserved, and their omental branches individually ligated. The spleen is not removed, but the short gastric vessels are divided. A generous Kocher maneuver is carried out all the way to the lower end of the duodenal loop, such peritoneal deflection allowing the whole distal stomach and duodenum to be pulled cephalad without tension. The stomach is transected along a line some 5–6 cm from the lower palpable border of the tumor mass. The pyloric ring is successively dilated with Hegar dilators to a maximum size of #17, in preference to a pyloromyotomy or pyloroplasty. The upper end of the stomach is closed in two layers, an inner with catgut and an outer with silk sutures.

Attention is now turned to the specimen side (Fig. 2). With a tape around the gastroesophageal junction the tumor is pulled downwards. Two medium sized retractors are placed into the lower mediastinum on either side of the esophagus pushing the two pleura away but avoiding any pressure on the heart. With the lower esophagus fully exposed, its muscular layer is incised circumferentially about 3–5 cm above the palpable margin of the tumor. This is carried down to the readily identifiable mucosal layer. The two cut ends of the muscular layer spring apart as the specimen is retracted downwards. The tip of the index finger pointing upwards is now inserted in the plane between the outer muscular and the inner mucosal layer. With the upper rim of the muscular layer held apart by heavy traction sutures or Babcock clamps, the exploring index finger is insinuated into the loose submucosal layer of the thoracic esophagus. The indwelling nasogastric tube serves to identify the mucosal sleeve as finger dissection is continued upwards. Digital detachment of the mucosa from the muscle is continued upwards as far as possible, and in any case beyond the level of the aortic arch and carina, both of which are palpable. There is no risk of breaking through the muscular esophageal wall into the mediastinum as long as the tip of the index finger follows the course of the nasogastric tube. Mucosal stripping is greatly facilitated by continuous downward traction on the specimen. There is little active bleeding and no vessels are encountered that would require ligation or cauterization.

The cervical esophagus is next exposed through a long incision parallel to the anterior margin of the left sternocleidomastoid muscle (Fig. 3). It is mobilized and lifted into view by an encircling rubber tape, taking care not to put any pressure on the general course of the recurrent laryngeal nerve. The distal esophagus is not dissected out any further than the thoracic inlet. The pulled up esophagus is incised circumferentially down to its mucosal layer. Separation of the mucosal sleeve is now begun as from the abdominal side. Holding apart the edges of the distal muscular layer with heavy traction sutures or Babcock clamps, the tip of the index finger is inserted into the readily found plane between the mucosal and muscular layers. It is pushed downwards in a spiraling fashion around the mucosal sleeve, feeling all the time the indwelling nasogastric tube. The operator, standing on the patient's left side, can insert the right index finger downwards from the neck and the left index finger upwards from the abdomen until they meet in the newly established plane. Bimanual dissection is continued until the whole mucosal sleeve is felt to be separated from its encasing muscular envelope. At this stage the mucosal sleeve is transected in the neck and its whole length extracted intact from the abdomen. It may not come out as readily as expected. By grasping the specimen and exerting gentle and unremitting traction downwards, the entire thoracic esophageal mucosal sleeve is pulled out in one piece while still attached to the specimen below (Figs. 4A and B). There is remarkably little bleeding from inside the denuded muscular tunnel, and what bleeding occurs stops spontaneously within a few seconds. Using the indwelling nasogastric tube as a guide, the index fingers of the two hands can be reinserted from above and below to further dilate the muscular channel by gentle lateral pressure.

The mucosal coring out process can be easy or difficult depending on the completeness of the blunt digital dissection. An eversion maneuver can also be used by removing the initial nasogastric tube and inserting another one through a small hole made into the mucosal sleeve just above the tumor. This tube is pushed into the neck and its tip tied to the mucosal sleeve and pulled out from below. Neither forceful extraction nor vigorous pulling is needed if digital dissection has been thorough.

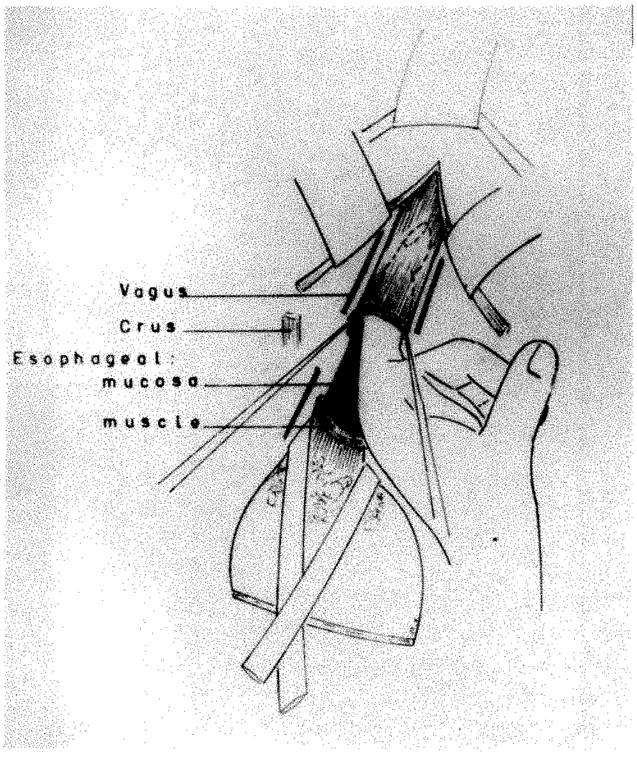

FIG. 2. The fundus of the stomach, involved by cancer of the cardia or attached to a lower esophageal cancer, has been separated from the rest of the normal stomach. The esophageal muscular layer has been incised circumferentially down to its mucosal layer. Downward traction on a tape placed around the gastroesophagel junction exposes a segment of the intact mucosal tube. Holding apart the upper rim of the muscular layer, the index finger is pushed into the plane between the esophageal muscle and mucosa to begin digital separation of these two layers upwards into the thorax.

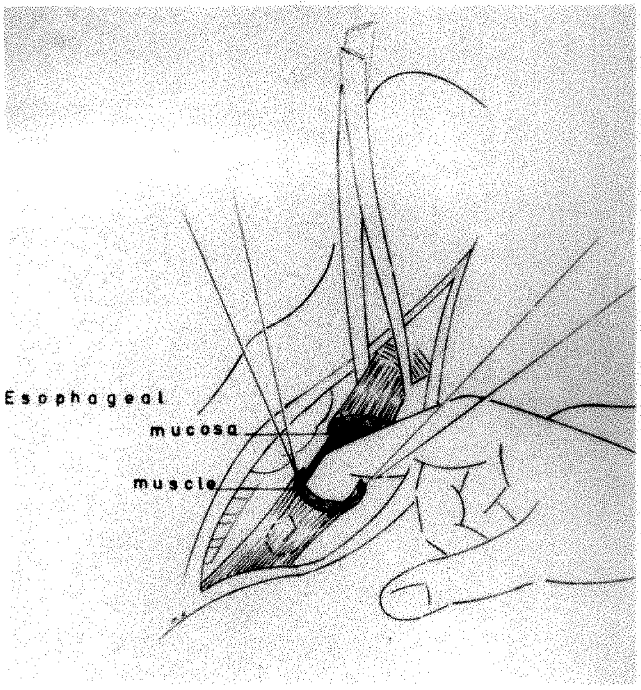

FIG. 3. The cervical esophagus has been exposed through an incision parallel to the anterior border of the left sternocleidomastoid muscle, and has been lifted out from behind the trachea. Its muscular layer has been incised circumferentially down to the mucosal layer. Pulling upwards on a tape placed around the upper part of the cervical esophagus creates a gap between the two ends of the divided muscular layer. Holding apart the rim of the distal muscular wall with traction sutures, the tip of the index finger is insinuated between muscle and mucosa, and digital separation of these two layers is continued downwards into the thorax.

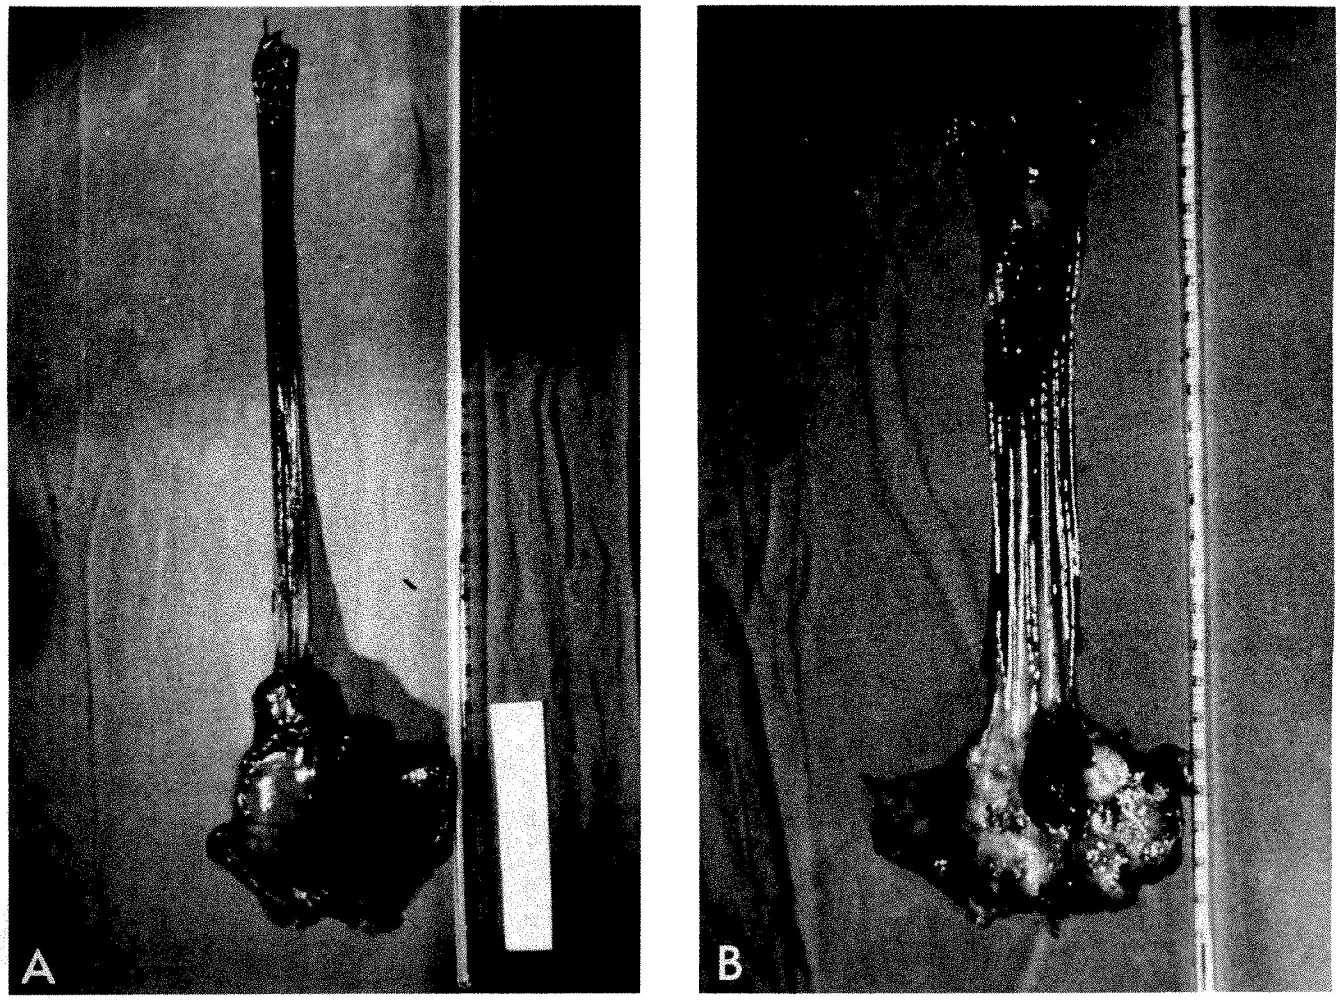

FIGS. 4A and B. *A*. The removed but unopened specimen of Patient C showing the gastric fundus involved by an adenocarcinoma of the cardia. A short segment of esophageal muscle projects upwards from the fundus. The full length of the stripped-off esophageal mucosal sleeve remains attached to the specimen. *B*. Same specimen, opened.

The previously prepared gastric or colon segment is next pulled into the neck from within the esophageal muscular channel for a cervical anastomosis (Fig. 5). The apex of the stomach, or closed proximal end of the colon, is fixed temporarily to the blunt end of an indwelling catheter. Pulling on the tip of the catheter from the neck with the right hand, the surgeon's left hand guides the bowel segment up into the lower opening of the muscular tube and out its upper end in the neck, avoiding any stretching or axial rotation. An end-to-side one layer esophagogastrostomy, or esophagocolostomy, is carried out in the neck between the proximal esophagus and a convenient site on the gastric or colonic wall. A small bore plastic catheter is put down through the nose by the anesthetist, and threaded across the anastomosis for temporary postoperative decompression of the pulled-up bowel segment. A narrow penrose drain is inserted down to the thoracic inlet region and the cervical incision closed.

A temporary feeding jejunostomy is performed, bringing the end of the jejunostomy catheter out in the left lower quadrant. The abdomen is closed without drainage. A chest film is taken in the operating room to detect and treat any unsuspected pneumothorax.

Clear fluids in small portions are started by mouth on about the third or fourth day if the abdomen is soft and peristalsis is present. Oral feedings are gradually increased in amount, and soft solids added by about the seventh postoperative day. Jejunostomy feedings are begun if there is any doubt about the patient's ability to tolerate sufficient fluids by mouth, or if there are signs of cervical anastomotic leakage.

Results

There was no 30-day postoperative mortality rate. Patient A died suddenly at home 2½ months after operation, presumably from a myocardial infarction. The other nine patients have been seen postoperatively at regular monthly intervals, the longest follow-up period being 6 months, the shortest 6 weeks. Postoperative complications, were of two types. The first consisted of pulmonary problems, mainly atelectasis and pleural effusion. The latter varied from 200 to 350 mL in amount and was seen mostly on the third to fifth postoperative day. During thoracentesis Patient I experienced transient cardiac arrest, which reverted promptly and without untoward results. There were no wound infections, and no patient had to be reexplored for bleeding or deep-seated localized sepsis. Patient G remains somewhat hoarse, most likely because of damage to the left recurrent nerve during mobilization of the cervical esophagus.

The other type of complication was leakage from the cervical anastomosis. This occurred in four patients. Leakage stopped within about 4 days in one case, but the patient had to be readmitted a month later for surgical release of an anastomotic stricture after two dilatations had failed to enlarge the narrowed area. Leakage stopped spontaneously within about 3 and 7 days, respectively, in the second and third cases. In a last patient the leakage continued intermittently for some 3 weeks after discharge from hospital without interfering with normal eating.

In terms of palliation, namely, the ability to eat comfortably and gain weight, all ten patients were satisfied with the results following operation.

Discussion

The concept behind the EEPT technique is not a new one. Essentially, one segment of bowel is pulled through the lumen of another segment from which the mucosal lining has been removed, thereby avoiding damage to the latter's outside structures. For the lower end of the GI tract this technique has proven suitable in the treatment of Hirschsprung's disease and familial polyposis of the colon since pelvic structures outside the rectum are not injured. For the upper end of the GI tract certain esophageal disorders should, theorectially, also be amenable to such an approach. Whatever segment of the GI tract is passed from the abdomen into the neck, it is kept within the anatomic confines of an esophageal muscular tube, avoiding injury to mediastinal structures. This pathway is also the shortest of all available routes to bridge the gap between the two ends of the alimentary tract after an esophagectomy.

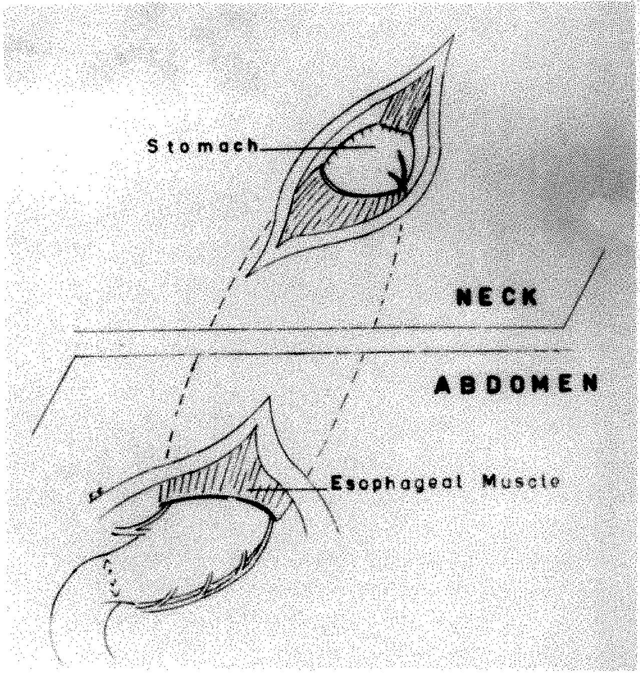

FIG. 5. The previously prepared distal stomach has been pulled from the abdomen into the neck through an accommodating thoracic esophageal muscular tunnel, and the cervical esophagogastrostomy has been completed.

Surgeons have known for some time that the mucosal lining of the esophagus is its strongest layer. This nonkeratinized squamous epithelium can be separated from the loose areolar type of connective tissue of the underlying submucosa with surprising ease, with some of the submucosa remaining attached to the mucosa. The intramural intrinsic blood supply of the esophagus was studied by Potter and Holyoke in 1950.[6] Segmental arterial branches of the aorta were found to penetrate at right angles the outer longitudinal and inner circular muscle bundles to become rapidly lost in the highly distensible submucosal layer. This could explain the paucity of active bleeding after stripping of the esophageal mucosa. In the endorectal pull through technique infiltration with saline or epinephrine solutions is sometimes necessary to facilitate dissection and minimize bleeding. Such measures need not be taken during removal of the esophageal mucosa.

Apparently Rehn in 1914 first proposed extraction of the esophageal mucous membrane to avoid bleeding.[7] The proposition was not applied clinically. One reason for this may have been the fact that resection of the esophageal tumor itself, in the hope of a possible cure, has always been foremost in the minds of surgeons. Revival of esophagectomy without thoracotomy, and its recent popularity in some center,[8–10] may also have kept dormant the idea of esophageal mucosal stripping.

TABLE 2. *Published Reports on Postoperative Leakage from Cervical Esophagogastrostomy*

	Technique of Cervical Anastomosis	No. of Patients Operated	No. of Patients with Leakage (%)
Barbier et al.[13]	Two layer	25	9 (36)
Caracci et al.[5]	Two layer	9	2 (22.2)
Finley et al.[1]	Not stated	34	7 (20)
Goldfaden et al.[8]	Two layer	29	2 (7)
Orringer[14]	Two layer	92	3 (3)
Shahian et al.[15]	Not stated	26	4 (15.4)
Steiger and Wilson[16]	Two layer inkwell	21	4 (19)
Tryzelaar et al.[17]	Two layer	13	1 (8)

That esophageal stripping and the passing of a segment of bowel through the remaining muscular tunnel is technically possible, and can be done with relative ease and negligible blood loss, was shown in our preliminary three cases using the direct vision transpleural route. It was reasoned that by restricting the technique to tumors of the lower esophagus and cardia, a thoracotomy would not be necessary at all, while extraesophageal mediastinal structures could be kept out of surgical harm's way. This assumption was substantiated on the basis of the clinical experience with ten consecutive cases of cancers of the lower esophagus and cardia. For malignancies in this location the vagus nerves had to be cut since they ran too close to the tumor. However, should the EEPT technique prove applicable to treatment of some benign lesions of the esophagus, the vagus nerves could well be spared.

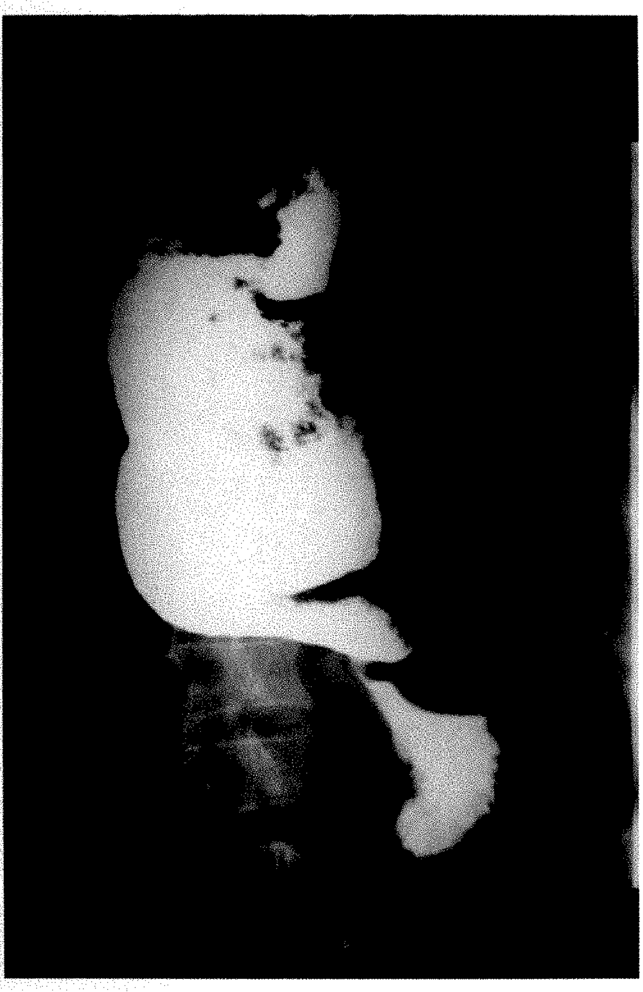

FIG. 6. Barium swallow of patient H showing free expansion of a functional stomach resting within the esophageal muscular tunnel.

There was no 30-day in-hospital mortality rate in this group of ten patients. This was perhaps related to the relatively young age of patients in this series as compared to esophageal cancer patients in general. None of the ten patients in whom EEPT was performed was either severely debilitated or suffered from any serious pulmonary disorders. None had severe anemia or needed preoperative nutritional preparation, and none required postoperative pulmonary support. The average operative blood loss was less than 800 mL; only Patient E with an unresectable tumor received about 1500 mL of whole blood during unsuccessful attempts at its removal. Avoidance of thoracotomy was not the overriding reason for using the EEPT technique in any of these ten patients. Nevertheless, the clear impression was that their overall postoperative course was relatively benign. And this might well be attributed to avoidance of thoracotomy.

The pleural space was not knowingly entered during the operation, and such postoperative pulmonary problems as consolidation and effusion were managed with relative ease. No mediastinal bleeding, tracheal injury, or chylothorax, as has been reported for transhiatal esophagectomy,[11,12] was encountered.

Leakage from the cervical anastomosis in four patients was more disconcerting. It stopped spontaneously or became insignificant within a matter of days. This incidence of anastomotic leakage was greater than that reported for other series of patients treated by the extrathoracic approach (Table 2). It seems unlikely that pressure from the encasing esophageal muscular tunnel could have caused relative ischemia at the apex of the pulled-through stomach in the neck. The esophageal muscular tube was found to be thin-walled, distensible, and not compressing its new contents. Barium swallow of Patient H taken 2 weeks postoperatively, showed a commodious stomach (Fig. 6). In none of the four patients who developed cervical leakage was there any particular difficulty encountered in bringing the stomach up into the neck. Intraluminal dilatation of the pyloric sphincter with Hegar dilators, instead of pyloroplasty or pyloromyotomy, was also an unlikely reason since it was done for all patients. The real culprit may well have been the use of a single layer suture for the cervical anastomosis in this series. A two-layer technique is planned for future cases.

Stripping of the esophageal mucosa was not easy at times in the beginning. But once digital detachment of the mucosa from the muscular layer was complete, the entire mucosal sleeve could be extracted atraumatically in every case with gentle and steady traction. Likewise, guiding the stomach or colon into the neck required patience as well as judgment regarding the required length of the prepared bowel segment, while paying attention to avoid axial rotation.

The procedure was deliberately restricted to cancers of the cardia and lower esophagus. Certain limitations as well as possible expansion of the scope of the operation were noted.

The exact location of tumor in Patient I was misjudged on barium swallow and found at operation to reach higher than expected. This confirmed a prior suspicion that even with maximal exposure of the lower esophagus through the abdomen, mucosal stripping would not be easy if the tumor extended very high above the gastroesophagal junction. Digital dissection of the mucosal sleeve would appear to be difficult to start under direct vision if the upper border of the esophageal cancer lies higher than 12–15 cm above the gastroesophageal junction. For this reason EEPT without thoracotomy would not seem applicable to middle and upper third esophageal cancers. No cases with primary cervical esophageal cancer were seen during the study period, but tumors at this level would seem eminently suitable for treatment with the EEPT technique.

On the other hand, distal extension of the tumor presented no technical problems but provided a new opportunity. Patient G was found to have a linitis plastica type of cancer involving the whole stomach. There were no obvious liver metastases, and total gastectomy was readily carried out. GI continuity was reestablished in this case by guiding an isoperistaltic segment of left colon through the esophageal muscular tunnel into the neck for a primary cervical anastomosis. The final colonic food resceptacle was more spacious than any that could have been fashioned by the use of a jejunal loop (Fig. 7). The additional cervical anastomosis in this case was worth the larger gastric pouch created. This patient was eating a full-course meal three times a day, and had gained 5 kg in weight on follow-up visit 4 months later. In Patient E the EEPT technique became essentially a bypass maneuver for an unresectable cancer of the cardia. The mobilized distal stomach in this case was pulled up alongside the unresectable tumor and guided through the esophageal muscular tunnel for a cervical anastomosis. The patient was alive and eating comfortably when seen about 4 months after discharge from the hospital but had continued to lose weight.

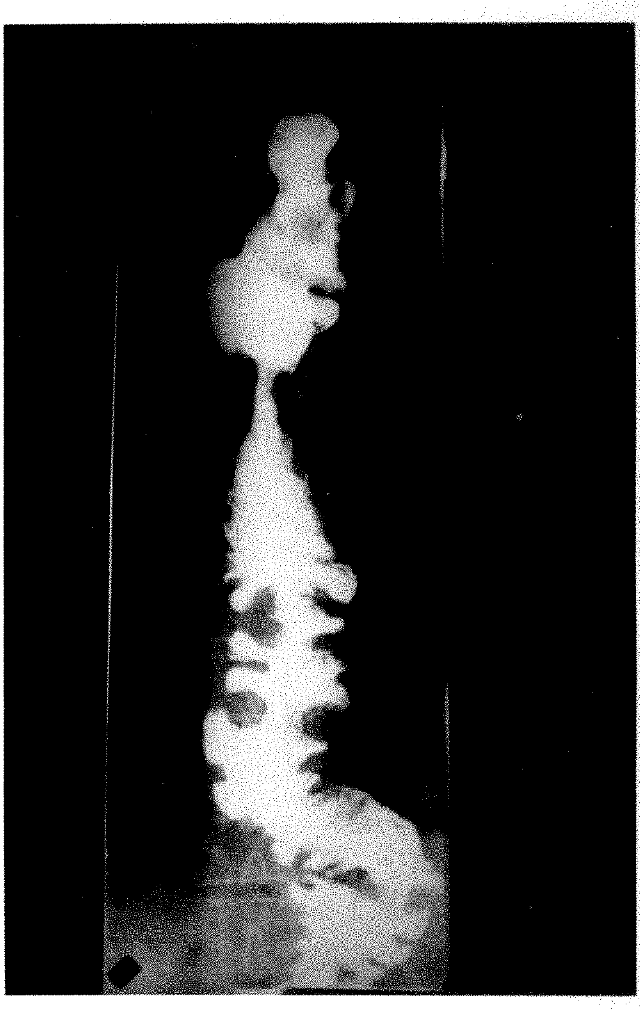

FIG. 7. Contrast study in Patient G after isoperistaltic left colon interposition within an accommodating thoracic esophageal muscular tunnel.

Cancers of the esophagus and cardia are said to advance submucosally upwards for a distance of about 5–6 cm.[18] To clarify this point, the lower 5-cm portion of the esophageal mucosal sleeve attached to and extending above the resected specimen was sectioned at 1-cm intervals and studied histologically. No proximal submucosal extension of the tumor could be seen beyond the 1-cm level from the upper margin of the tumor. The rim of the esophageal muscle projecting upwards from the proximal part of the specimen was also examined histologically and found not to be involved by tumor in any of the removed specimens.

The proposed EEPT approach is in accord with the view that all symptomatic patients with cancer of the esophagus should be operated on—for palliation if possible, and for cure if circumstances are fortunate.[19] In terms of relieving their distressing dysphagia and allowing them to eat comfortably and return to normal life within a short time, this operative approach was well received by all ten patients in this series.

The EEPT technique is basically a palliative operation for cancers of the lower esophagus and cardia. As such, it should be compared with the other two palliative approaches available for tumors of this location, namely, the conventional transthoracic and the transhiatal extrathoracotomy operations. The *en bloc* removal of all expendable surrounding normal structures is curative by design.[20] The limits of tumor resectability and the opportunity for lymph node removal with the EEPT technique are the same as with the other two palliative approaches. The distance of the gastric transection line from the lower margin of the tumor is also the same. The upper level of mucosal resection margin is as high as it could conceivably be. An occasional cure will be achieved with either of the two standard palliative approaches if the cancer happens to be at an early stage of its growth. The total number of cases in this series has been too small and the follow-up time too brief to permit any statement regarding the likelihood of cure in any of the ten patients in whom resection of the whole tumor with removal of all involved contiguous nodes was carried out.

Editor's Note

The author has provided the following additional information.

Since submission of the manuscript, seven additional cases with squamous cell cancer of the lower esophagus or adenocarcinoma of the cardia were operated on in a uniform manner using the endoesophageal pull through technique described. Two male patients aged 79 and 83 died in the immediate postoperative phase, the first of massive myocardial infarction and the second with superior mesenteric artery occlusion and bowel gangrene. Of the remaining five patients two developed transient leakage from the cervical esophagogastrostomy. The additional experience with these seven patients reconfirmed the need to develop with meticulous care the anatomic plane between the esophageal mucosa and muscle, both in the abdomen and in the neck.

Follow-up on all patients reported initially shows that of the three preliminary cases operated on by the standard transthoracic approach, one is alive at 10 months and two died, having died at 10 and 9 months, respectively. Of the ten cases in whom a thoracotomy was not done and the stomach or colon was guided through the denuded esophageal muscular tunnel for a primary anastomosis in the neck by this EEPT method, three have died at 2.5, 5, and 6 months, respectively. The remaining seven patients operated on by the EEPT technique are alive and eating comfortably, the longest survival being 11 months, the shortest 5 months. Among the survivors is the patient who underwent total gastrectomy with left colon pull through into the neck without opening the chest.

Acknowledgments

The expert anesthesiology management of Dr. Mohammad Rezvan is gratefully acknowledged. I want to thank Dr. Hakob Papazian from the Department of Pathology of Modarress Hospital for pathological studies performed, and Dr. Francis D. Moore of Harvard Medical School for reviewing and editing the manuscript.

An Accounting: The True Costs of DVT

DVT can be a silent killer, developing over time and striking with little warning. More than 80% of fatalities from DVT-related pulmonary embolism occur within two hours after the first symptoms appear.

Much of the human and financial cost of DVT is also hidden. Consider that over 850,000 people in the U.S. suffer from chronic venous insufficiency and leg ulcers following DVT, with a loss of two million work days a year, untold pain and a heightened risk of recurrence of thromboembolism.

The total annual cost of treatment for DVT and pulmonary embolism for one patient is over $4,000. That's an eye-opening figure. It may also catch your attention that hospitals may be at risk for a fair share of that. If DVT develops as a complication of hospitalization, treatment cost may not be reimbursed under some DRG guidelines.

There is an effective response: prophylaxis.

The best way to combat DVT is to prevent its occurrence. The following landmark study found prophylaxis is cost effective.

Numerous studies and clinical experience have demonstrated that prophylaxis works in medical terms. Here, we can also see its impact outlined in health care dollars.

With a risk assessment/selected treatment program of routine prophylaxis at a level specified by physician judgment, all evidence indicates that the cost of DVT prevention will be far more than made up in savings. At a very conservative 50% reduction level, we estimate that overall treatment costs would decline between 15-20%.

Better health care. Cost savings. It's an unbeatable combination.

(Kendall can provide a wide variety of informational and educational materials on DVT prevention, as well as in-hospital programs. To answer your needs, please contact: Kendall Healthcare Products Company, 15 Hampshire Street, Mansfield, MA 02048)

Deadline: Copy received by the 15th of month will run in the second following month's issue, e.g. November 15th for January issue. Ads received after the 15th will run in the next available issue.

ALL SURGICAL SPECIALTIES, NATIONWIDE. Excellent Quality Of Life And Compensation. **Dr. Len Goodman, SMA, P.O. Box 25786, Charlotte, NC 28229. 704-536-2527.**

BC/BE general and vascular surgeon to join 3 busy surgeons in growing multispecialty clinic of 40 physicians. Located in college town of 40,000, 1 1/2 hours from Milwaukee and Chicago, 1 hour from Madison, Wisconsin. Guaranteed first-year salary with incentive, excellent benefits and equal participation in clinic ownership. Clinic located across the street from modern, progressive hospital. Send C.V. to **James F. Ruethling, 1905 Huebee Pkwy., Beloit, WI 53511.**

BC/BE General Surgeon to associate with two active internists in NE Wisconsin. New clinic and modern hospital with state of the art ICU. **Box ANN4B, J.B. Lippincott Company, East Washington Square, Philadelphia, PA 19105.**

Boston University Medical Center—**OPPORTUNITIES:** For academically-oriented board certified (or eligible) surgeons with interests in Vascular, Trauma Surgery. Critical Care or Neurosurgery at a Level I Trauma Center in Boston. Contact **Division of Surgery, Boston University Medical Center, 88 E. Newton Street, Boston, MA 02118.** Attn: Dr. James Menzoian (Vascular), Dr. Erwin Hirsch (Trauma), Dr. Richard Dennis (Critical Care), Dr. Edward Spatz (Neurosurgery). Boston University Medical Center is an Affirmative Action Equal Opportunity Employer.

Chairman, General Surgery Department—San Bernardino County Medical Center is seeking a new Chairman of Dept. of General Surgery. Individual will have major clinical and academic responsibilities at SBCMC and must qualify for academic appointment at Loma Linda University School of Medicine. Inquiries should be accompanied by curriculum vitaes and addressed to: **M. Kenneth Mudge, M.D., Chairperson, Dept. of General Surgery Search Committee, c/o Medical Director's Office, Rm. 101, San Bernardino County Medical Center, 780 E. Gilbert St., San Bernardino, CA 92404.** Equal opportunity employer.

CHIEF OF SURGERY—The Veterans Administration Medical Center, East Orange, NJ in cooperation with the Department of Surgery of the New Jersey Medical School, is seeking a Chief of Surgery for the VA. The Medical Center is a 750 bed, tertiary-care institution with 222 beds on the Surgical Service. It is a fully integrated, core teaching hospital for the Department of Surgery at the Medical School, the vast majority of faculty members holding appointments at both institutions. It has the second largest number of surgical residents in the Training Program after University Hospital. The Surgical Service is comprised of Sections of Generals Surgery, Vascular Surgery, Surgical Oncology, Thoracic Surgery, Anesthesiology, Neurosurgery, Otolaryngology, Orthopedics, Ophthalmology, Urology, Plastic Surgery and Surgical Intensive Care, all of which are integrated with the appropriate Department at the Medical School. The successful candidate will be board certified in Surgery and will have sufficient academic credentials to qualify for appointment as an Associate Professor or Professor of Surgery. The individual will be expected to be an excellent clinical surgeon, to have the administrative capabilities to lead a large and active Service and to have the ability to support teaching and research programs. Send a copy of curriculum Vitae to: **Willard A. Burns, M.D., Chairman, Surgery Search Committee (113), VA MEDICAL CENTER, East Orange, NJ 07019.**

General Surgeon—(BC/BE) to join busy 35 physician multispecialty group in Northeastern Massachusetts 35 miles from Boston. Excellent first year salary guaranteed with eventual association. Please send C.V. and references to **Leonard Block, M.D., Medical Associates, 199 Chelmsford Street, Chelmsford, MA 01824—(617) 256-6511.**

General Surgeon—family-oriented community on Ohio/WVA boarder seeks surgeon to establish private practice with coverage. Progressive community hospital, excellent referral base; above average income guarantee; abundant sportsman and recreational activities. Call **Ms. Picone at (201) 746-8877** or send resume to **Executive Health Search Consultants, 39 S. Fullerton Avenue, Montclair, NJ 07042.**

GENERAL SURGEONS: Newly established prepaid group practice desires to begin offering general surgery services. Looking for general surgeons interested in establishing and building a department. Physicians must be from high quality residency programs. Positions available immediately. Address C.V. to: **Larry A. Oates, M.D., Regional Medical Director—ANS, Carolina Permanente Medical Group, P.A., 3120 Highwoods Boulevard, Raleigh, North Carolina 27604, (919) 878-9870.**

KANSAS: We are seeking a general surgeon interested in a full-time private practice opportunity in the greater Kansas City area. For further information, please send current CV to **Linda Smith, Central Business Services, Inc., 3101 Broadway, Suite 1000, Kansas City, Missouri 64111; or call 1-800-821-5147 or 816-561-1025.**

The Challenge of DVT: Step One

T.E.D./SCD

THE EVIDENCE IS IN. Prophylaxis works against Deep Vein Thrombosis. Major Reductions in occurrence and significant cost savings.

T.E.D.® Anti-Embolism Stockings provide a first step in a prophylactic program. For all patients – low, moderate and high risk. They provide the first line of defense against venous stasis – a key factor in DVT development – and can be used effectively with Kendall's SCD™ Sequential Compression Device.

Together, they provide both static and dynamic compression. The static compression of T.E.D. Anti-Embolism Stockings works to provide continued patient protection over extended periods of risk. The Sequential Compression Device provides dynamic compression for periods of increased risk.

Both offer distinct advantages.

The SCD sequential graduated pneumatic compression device performs to produce peak blood flow velocity over conventional uniform devices.

And T.E.D. Stockings. They're simply the leader. Because of their optimal pressure gradient which enhances blood flow velocity. What is really important though, is that they are still the one and only graduated compression stocking clinically proven to reduce the incidence of venous thrombosis.

The cost? Negative. Because T.E.D. Anti-Embolism Stockings and the SCD Sequential Compression Device perform to lessen DVT treatment costs. Together or separately.

We'd be happy to send you the evidence behind that claim. Just write to:
Kendall Healthcare Products Company

MOUNT VERNON HOSPITAL
FAIRFAX HOSPITAL SYSTEM

ONCOLOGY FELLOWSHIPS

Positions are available to physicians who are licensed to practice medicine in the United States and have at least two years of training in medicine or surgery.

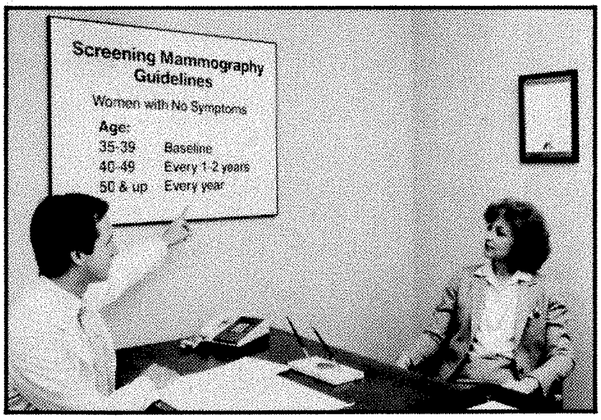
The oncology training offers a one year fellowship beginning July 1, 1988 and July 1, 1989. The program consists of primary clinical responsibility of both in-patients and out-patients undergoing treatment with various biologic response modifiers and chemotherapeutic agents.

Continuity of patient care, principles of patient management, and design and conduct of clinical trials are stressed. Seminars and conferences on biostatistics, immunology, cell biology, molecular biology, clinical pharmacology, and diagnostic pathology and radiology are given regularly.

The annual salary is $45,000.00, including medical and dental insurance, life insurance, vacation, and sick leave. In addition, moving and travel expenses are available.

For further information please contact:

Medical Director, Clinical Cancer Institute
Mount Vernon Hospital
2501 Parker's Lane
Alexandria, VA 22306
(703) 664-7102



What will you tell her about screening mammography?

Many of your patients will hear about screening mammography through a program launched by the American Cancer Society and the American College of Radiology, and they may come to you with questions. What will you tell them?

We hope you'll encourage them to have a screening mammogram, because that, along with your regular breast examinations and their monthly self examinations, offers the best chance of early detection of breast cancer, a disease which will strike one woman in 10.

If you have questions about breast cancer detection for asymptomatic women, please contact us.

Residency Wanted: Three year training in Internal Medicine and two year experience in Cardiovascular and Thoracic Surgery seeking residency in General Surgery. Excellent references. Reply **Box ANN4A, J.B. Lippincott Company, East Washington Square, Philadelphia, PA 19105.**

SURGICAL ONCOLOGY, ASSISTANT PROFESSOR— Department of Surgery, Case Western Reserve University and Cleveland Metropolitan General Hospital are recruiting another individual with an academic commitment to oncology to join an established group. Basic research experience is essential. Funding and protected time available for scholarly activity. Case Western Reserve University and Cleveland Metropolitan General Hospital are equal opportunity, affirmative action employers. Women and minority candidates are encouraged to apply. Send curriculum vitae and two references to: **Anthony L. Imbembo, M.D., Director, Department of Surgery, Cleveland Metropolitan General Hospital, 3395 Scranton Road, Cleveland, Ohio 44109.**

SURGERY: TRAUMA—Board eligible surgeon to join full-time faculty in growing Trauma Program in a junior position; no fellowship required. Preference given to those completing General Surgery residency in June, 1988, and planning career in Trauma Surgery. Interested candidates contact: **Stanley Z. Trooskin, M.D., Chief, Division of Trauma Surgery, UMDNJ-Robert Wood Johnson Medical School, One Robert Wood Johnson Place, CN-19, New Brunswick, NJ 08903-0019.** An equal opportunity/affirmative action employer m/f/h/v.

The Department of Surgery at the University of Utah School of Medicine seeks a board certified/eligible general surgeon with specialized interest and training in endoscopy and laser therapy. Appointment will be at the instructor or assistant professor level depending upon qualifications. Interested applicants should send an updated curriculum vitae to: **William A. Gay, Jr., M.D., Professor and Chairman, Department of Surgery, University of Utah, School of Medicine, 50 North Medical Drive, Salt Lake City, Utah 84132.** Deadline for receipt of applications is April 30, 1988. Applications postmarked or submitted after the closing date may be considered if no qualified candidates have been identified by that time. The University of Utah is an Affirmative Action/Equal Opportunity Employer.

Thoracic Surgeon experienced in adult cardic, general thoracic and peripheral vascular surgery is needed to join 195 physician multispecialty prepaid group in Hawaii. Board certified associate. Excellent fringe benefits. Malpractice paid. Please direct curriculum vitae: **Hawaii Permanente Medical Group, Inc., 3288 Moanalua Road, Honolulu, HI 96819.** (An Equal Opportunity Employer)

University of California, San Francisco—Fresno Medical Education Program invites applications for Chief, Surgical Service, Veterans Administration Medical Center; Fresno, CA. Opportunity for board certified experienced general surgeon to lead a strong academic program affiliated with UCSF. Responsibilities include supervision of the general surgical services and residency program of a 260-bed medical center. Hospital is located in the agriculturally rich central San Joaquin Valley with excellent schools, museums, climate and immediate access to the Sierra Nevada mountains nearby. Address inquiries to **Dr. Malcolm F. Anderson, Chairman, Surgical Search Committee, VA Medical Center, 2615 E. Clinton Ave., Fresno, CA 93703. (209) 228-5371.**

Prognostic Significance of DNA Aneuploidy in Stage I Cutaneous Melanoma

The prognostic significance of DNA aneuploidy was studied retrospectively in 177 Stage I cutaneous melanomas. DNA content was determined by flow cytometry of propidium iodide-stained nuclei recovered from formalin-fixed, paraffin-embedded material. Of 162 evaluable histograms, 124 were diploid, 35 aneuploid, and 3 tetraploid. Aneuploidy strongly correlated with established predictors of unfavorable prognosis, namely, thickness $p < .005$, level $p < 0.005$, ulceration $p < 0.005$, and presence of vertical growth phase $p < 0.02$. Overall, aneuploidy was strongly correlated with recurrence ($p < 0.005$) and shorter disease-free survival ($p < 0.0001$). Aneuploidy was an independent predictor of recurrence for tumors < 1.5 mm thick ($p < 0.0001$) and ≥3 mm thick ($p = 0.031$). For melanomas 1.5–2.9 mm thick, aneuploid tumors had a 27% higher recurrence rate than diploid tumors (63% *vs.* 36%). This was not statistically significant ($p = 0.247$). In a multivariate analysis of common predictors stratified by thickness, DNA aneuploidy was the most significant independent parameter ($p < 0.002$). DNA content appears to be an important stratification parameter for Stage I cutaneous melanoma.

PATIENTS presenting with Stage I cutaneous melanoma have a highly variable clinical course. This variability has resulted in the description of numerous histologic and clinical prognostic factors used to help in the development of treatment plans. The most important of these factors includes level of invasion, tumor thickness, ulceration, vertical growth phase, cell type, mitotic index, host inflammatory cell response, regression, location of lesion, and patient sex.[1-10] While none of these is ideal, tumor thickness appears to be the most highly predictive factor, whether considered alone or in combination with other parameters.[11]

Using tumor thickness, patients can be identified who have either an excellent prognosis (lesions < 0.76 mm thick) or poor prognosis (lesions > 4 mm thick). However, exceptions to this rule exist no matter how thickness is used to stratify melanoma patients. Additional prognostic methods are clearly needed since it is evident that morphologic parameters are not always adequate to predict the biologic behavior of melanomas.[12]

The value of DNA content determination by flow cytometry (FCM) in predicting biologic behavior has been strongly suggested in several solid tumor models.[13-15] Recently, it has been shown that formalin-fixed, paraffin-embedded primary melanomas can be conveniently and reliably prepared for analysis by FCM.[16-18] Furthermore, this same report suggested that the presence of abnormal DNA content (DNA aneuploidy) in primary cutaneous melanomas correlates with increasing tumor thickness and incidence of recurrence. The conclusions that could be drawn from this study were limited by the small patient base, lack of survival data, and lack of a multivariate analysis of DNA aneuploidy in relation to other accepted prognostic factors. We sought to address these shortcomings in the present study of 177 patients with primary Stage I cutaneous melanoma. This new study shows that DNA aneuploidy is highly predictive of recurrence and shorter disease-free survival when this factor is considered alone. More importantly, it is also highly significant in a

multivariate analysis in which the other significant prognostic factors are considered.

Materials and Methods

Patient Selection

The study material consisted of single paraffin blocks from each of 177 primary cutaneous melanomas from 177 patients. This material originated from three sources: Rush Presbyterian St. Luke's Medical Center, Chicago, IL (63 patients); Baptist Hospital, Birmingham, AL (22 patients); and the University of Alabama Melanoma Registry, Birmingham, AL (92 patients). Cases were selected on the basis of paraffin block availability and included all Stage I melanoma patients seen between 1969 and 1985 at Rush. Only those lesions initially fixed in buffered formalin prior to paraffin embedding were included for study (material fixed in most other common fixitives, for example, Bouin's, has been shown to be unsuitable for this technique).[19]

A hematoxylin and eosin-stained section of each case was studied without previous knowledge of the FCM data. Each case was evaluated according to Breslow's thickness, Clark's level, growth pattern (radial *vs.* vertical), cell type, presence of ulceration, and mitotic index.[5,20-24] Initial clinical data collected for each patient included patient age, patient sex, and anatomic location of the lesion.

Follow-up data were obtained from tumor registry records, hospital and office charts, and by direct patient contact. Patients dead of unknown cause without documentation of recurrence prior to death (two patients) were excluded from the study. Similarly, outpatients without documented follow-up were excluded from the study (12 patients).

Sample Preparation

All blocks processed for FCM were chosen to be representative of the tumor after evaluation. Preparation of the blocks was accomplished with a modification of the method of Hedley et al.[17,25] Thick sections (50 μm) from formalin-fixed, paraffin tissue blocks were dewaxed in xylene, rehydrated in graded ethanol solutions, and mechanically minced with scissors. The tissue slurry was then digested with 0.5% pepsin (Sigma, St. Louis, MO), in 0.9% NaCl at pH 1.5 for 30 minutes at 37 C to produce a suspension. The suspensions were further treated with Nonidet P40 (Sigma) and trypsin type IX (Sigma) according to the method of Vindelov et al.[26] to aid the production of a monodisperse suspension of bare nuclei. The suspension was washed, filtered through 41-μm nylon mesh to remove aggregates, and the concentration was adjusted to 2×10^6 nuclei/mL. The nuclei were then incubated for 10 minutes with 0.1 mg/mL Ribonuclease-A (Sigma), then stained for DNA with propidium iodide (Sigma) at 0.13 mg/mL for 15 minutes, and analyzed by FCM within 1 hour of staining. A conventional histologic section adjacent to the thick section was prepared in each specimen to verify the presence of tumor in the material prepared for FCM.

FCM Analysis

Nuclei were adjusted to a concentration of 5×10^5 nuclei/mL in dimethylsulfoxide-citrate buffer for FCM analysis as described previously.[27] The relative DNA content (red fluorescence) of 10^5 nuclei was analyzed in a Coulter Epics V (R) (Hialeah, FL) flow cytometer equipped with a Coherent (Worcester, MA) argon ion laser operating at 300 mW at 488 nm. All tumor samples contained diploid inflammatory and stromal cells, which served as an internal diploid standard as previously described.[27] The high voltage to the photomultiplier tube was adjusted so that the GIGO peak of the diploid cells was located in channel 50 of 256 total channels. Nondiploid populations were defined by the presence of discrete GIGO populations differing from diploid by at least 10%. The DNA index for nondiploid populations was calculated as the quotient of the channel of the nondiploid peak divided by the channel of the diploid peak.

Statistical Methods

The relationship between FCM results and conventional prognostic factors was made using the chi square test. Life table analyses were then performed and survival curves were calculated, using the method of Kaplan and Meier.[28] The entire population, as well as the populations grouped according to the various prognostic factors, was studied. The log rank test was used to determine if significant differences existed between these curves.[29] A multivariate analysis of prognostic factors was performed, based on the rank regression procedure described by Kalbleisch and Prentice.[30] Tumor thickness was used as the stratification variable.

Results

Flow Cytometry

Of the 177 patients initially selected, 15 were eliminated because of technical difficulty. Four of these had very low nuclear counts (<5000) after tissue preparation. Eleven samples with apparently adequate nuclear counts nevertheless yielded uninterpretable DNA histograms, defined as having no peak with a coefficient of variation less than 10%. Thus, interpretable histograms were obtained from 162 (92%) samples, even though many of the lesions were very small and some were more than 10 years old. Of the 162 samples with satisfactory histograms, 124 were diploid, 35 aneuploid, and three tetraploid (Fig. 1). The three tetraploid tumors were excluded from further analysis because of their small number and unclear relationship to melanomas with diploid or aneuploid DNA content, leaving 159 tumors for analysis.

Correlation Between DNA Content and Conventional Prognostic Variables

DNA content was compared to conventional prognostic variables including tumor thickness, Clark's level, ulceration, vertical growth phase, cell type, anatomic location and patient's sex (Table 1). Tumor thickness was significantly related to aneuploidy ($p < 0.005$). While five of 61 tumors less than 1.5 mm were aneuploid (8%), 15 of 38 lesions greater than 3.0 mm thick contained an aneuploid cell population (39%). Similarly, the association between aneuploidy and increasing Clark's level was significant ($p < 0.005$). Ulcerated lesions were more likely to be aneuploid than nonulcerated lesions ($p < 0.005$). The presence of a vertical growth phase was associated significantly with aneuploidy ($p = 0.02$). The association between DNA content and radial growth pattern (superficial spreading melanoma, nodular melanoma, lentigo maligna melanoma) was not significant. The association between DNA content and cell type was significant if epithelioid cell types were compared to all other cell types combined ($p < 0.05$). No significant relationship between ploidy and mitotic index was found. Unexpectedly, head, neck, and trunk melanomas had a significantly lower incidence of aneuploidy when compared to extremity melanomas ($p = 0.005$). No significant relationship between DNA aneuploidy and patient sex was found.

† Differences in survival curves for each variable were compared using the log rank test.

with a range of follow-up between 0.17 and 23.05 years. Within this group of patients, there were 95 documented recurrences and 50 patients who remained recurrence-free. Of the patients without recurrence, the range of follow-up was 0.17–23.05 years. This follow-up included three patients who died without evidence of disease at 0.19, 2.17, and 4.02 years after diagnosis.

The 33 patients with aneuploid tumors had a significantly higher incidence of recurrence and a significantly decreased 3- and 5-year disease-free survival time than the patients with diploid tumors ($p < 0.0001$, Table 2, Fig. 2). Increasing tumor thickness was similarly associated with a significant increase in recurrence rate and decreased disease-free survival time ($p < 0.0001$, Table 2). Increasing Clark's level, the presence of ulceration, the presence of vertical growth phase, and a cell type other than epithelioid were also associated with decreased disease-free survival (Table 2). Anatomic site, patient sex, or growth pattern were not associated with significant differences in disease-free survival.

Association of Disease-free Survival Stratified by DNA Content and Tumor Thickness

For melanomas < 1.5 mm thick, aneuploid tumors had a significantly increased recurrence rate and decreased disease-free survival when compared to diploid tumors ($p < 0.0001$, Figs. 3A and 4). For tumors 1.5–2.9 mm thick, the 5-year recurrence rate for aneuploid tumors was 63% compared to 36% for diploid tumors. However, the disease-free survival curves were not significantly different ($p = 0.247$, Figs. 3B and 4). Aneuploid tumors ≥3 mm had a 100% 5-year recurrence rate compared to 54% for their diploid counterparts. In this group the difference between disease-free survival curves was significant ($p = 0.031$, Figs. 3C and 4).

Multivariate Analysis

A multivariate analysis of prognostic factors based on the rank regression procedure described by Klableisch and Prentice[30] was obtained after stratification for tumor thickness (Table 3). DNA aneuploidy was found to be the most significant unfavorable prognostic factor after adjustment for thickness ($p = 0.002$). DNA content was followed by cell type (favorable characteristic; epithelioid, nevus, or spindle; $p = 0.022$) and vertical growth phase (favorable characteristic; no vertical growth; $p = 0.024$).

Discussion

Assessment of biologic potential in melanomas of the skin is an important and difficult problem in clinical oncology and pathology. The difficulty arises because of the great variability in the clinical course of apparently similar malignant melanomas.[23]

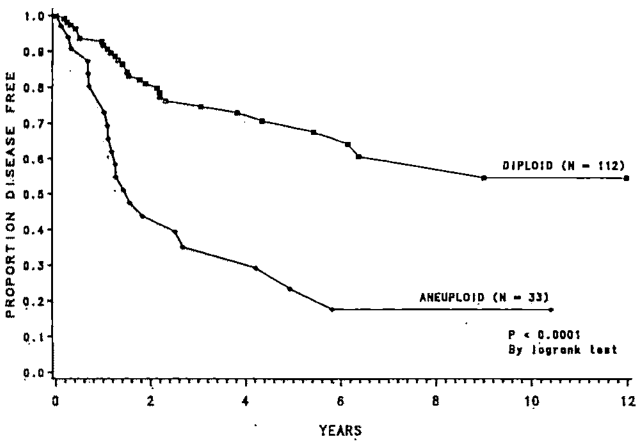

FIG. 2. Actuarial disease-free survival curves for 145 Stage I melanoma patients subdivided by DNA content (aneuploid *vs.* diploid). A significant difference in survival between the curves was found using the log rank test. The number of patients in each group is shown in parentheses.

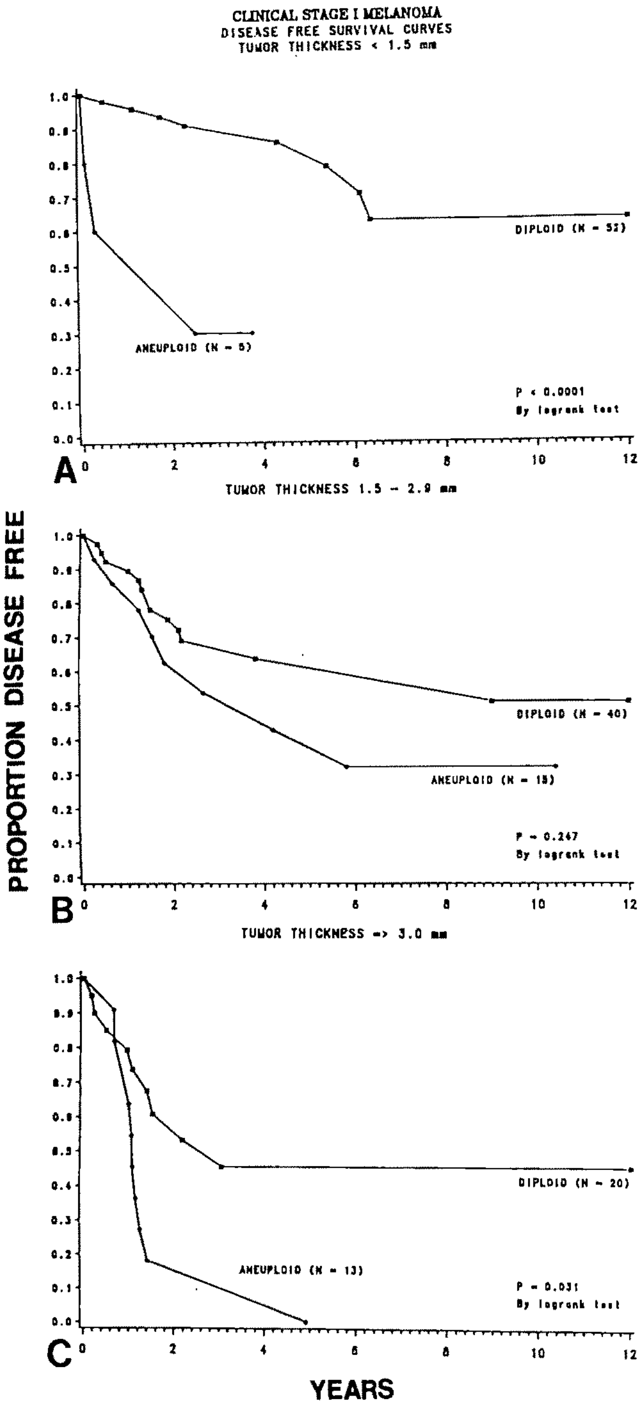
As a result of prognostic studies in patients with Stage I melanoma, there is general agreement that measuring lesion thickness (microstaging) is the single most important prognostic indicator.[6,11] Except for the most superficial lesions, patients with histologically similar lesions often experience vastly different clinical outcomes. This can make decisions about appropriate therapy difficult and subjective.[11,23,31] Clinical reports using thickness as a guide to determine the use of elective lymph node dissection present conflicting results, further underscoring the fact that present prognostic techniques may be inadequate.[32-35] Clearly what is needed is the establishment of reproducible criteria reflecting the potential of the tumor cells to invade and metastasize, presumably to be used in addition to the existing staging and microstaging criteria.



FIGS. 3A–C. Actuarial disease-free survival curves calculated for Stage I melanoma patients subdivided by tumor thickness (*A*. Tumors < 1.5 mm. *B*. Tumors 1.5–2.9 mm. *C*. Tumors > 3 mm.), and grouped according to DNA content (diploid *vs*. aneuploid). The log rank test was used to compare survival curves within each thickness subdivision. The number of patients in each group is shown in parentheses. DNA content (aneuploidy) significantly influenced disease-free survival for tumors < 1.5 mm and ≥ 3 mm.

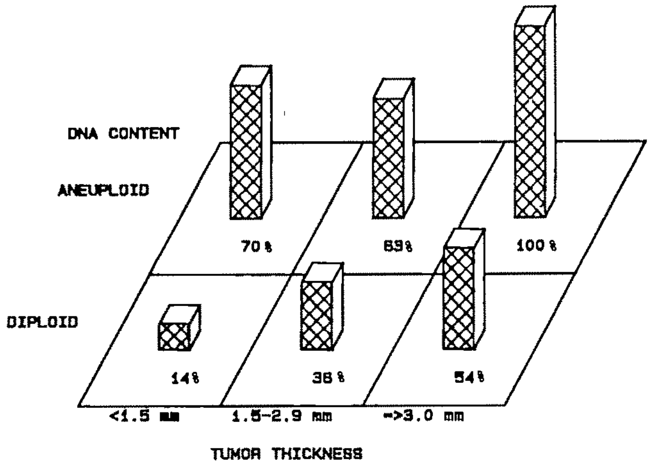


FIG. 4. Three-dimensional graph comparing 5-year recurrence rate, DNA content, and increasing tumor thickness. Within each thickness subgroup, aneuploid tumors had a higher recurrence rate than their diploid counterparts.

TABLE 3. *Multivariate Analysis of Prognostic Factors**

Factor	Chi Square (Log Rank Test)	P Value†	Favorable Characteristics
DNA content (adjusted for thickness)	9.7	0.002	Diploid
Cell type (adjusted for thickness and DNA content)	5.2	0.022	One of the following types: epithelioid, nevus, or spindle
Vertical Growth (Adjusted for thickness, DNA content, and cell type)	5.1	0.024	No vertical growth

* This analysis was based on the rank regression procedure described by Kalbeisch and Prentice.

† After stratification for tumor thickness, DNA content was found to be the most significant prognostic factor (with diploid being the favorable characteristic) followed by cell type and vertical growth.

The need for an improved prognostic system has led to the proposal of numerous histopathologic factors as additional prognostic guides. These include the presence of vertical growth phase, ulceration, number of mitoses, lymphocytic response, cell type, regression, and pigmentation.[5,20–24] None of these factors has been completely satisfactory. First, many of these factors are not significant independent prognostic predictors when tumor thickness is taken into account.[23] Second, assessment of some of these factors is subjective and qualitative, contributing to the persistent controversy surrounding their relative importance and practical value.[23]

Because of the limitations of subjective morphology for assessing the biologic potential of tumors, objective quantitative methods may yield important additional information. Quantitative DNA analysis has been performed on relatively large numbers of specimens from several solid tumors.[14] These studies have established that an abnormal DNA content, (DNA aneuploidy), is significantly related to the biologic potential of several tumors, including cancers of the colon, urinary bladder, prostate, and ovary.[13–15,36–40] The precise clinical value of these studies is still under study and can vary widely for different tumors.

Previously reported data on melanoma from our laboratory[16–18] and others[31,41,42] indicate a strong association between DNA aneuploidy and unfavorable clinical outcome. Our application of FCM to the study of melanoma was greatly facilitated by the development of the capability to recover intact tumor cell nuclei from paraffin blocks. This technique has allowed us to study a relatively high proportion of thin diploid lesions compared to previous studies where difficulty in obtaining adequate fresh tissue limited the analysis to thicker lesions. The reliability of this technique has been documented by Hedley, its originator,[24] and confirmed by others including ourselves.[25] The successful application to small specimens (such as cutaneous melanoma) may be related to our modification of Hedley's original technique, namely, appending a detergent-trypsin nuclear isolation technique to the acid pepsin technique of Hedley. This impression is based on observing the suspensions microscopically before and after the detergent-trypsin step; an increased yield of nuclei and fewer aggregates were routinely observed after this step.

The present study has revealed significant new information. First, it focused upon a large, unique population of patients with Stage I lesions and adequate clinical follow-up (mean: >4 years). Second, it examined the significance of DNA content on disease-free survival as a single factor and demonstrated the relationship of DNA aneuploidy with other unfavorable prognostic factors and shorter disease-free survival. Third, it examined the relative value of DNA aneuploidy compared with other important prognostic factors in a multivariate regression analysis stratified for tumor thickness. This multivariate analysis of prognostic factors demonstrated DNA content to be the most significant predictor of survival after thickness. Most importantly, it demonstrated that aneuploidy can be used to prognostically subclassify melanoma patients with lesions of defined thickness.

The ability to identify patients with thin (<1.5 mm) melanomas at relatively high risk for recurrence seems particularly important since these patients might be candidates for special treatment modalities. Conversely, patients in this thickness category (particularly those 0.76–1.5 mm) with diploid tumors could be reassured that their outlook was relatively favorable. The significant substratification results for the patients with thick lesions (>3.0 mm) also appear important for interpreting results of new adjuvant therapy approaches. Regardless of the thickness stratification used, these data demonstrate that aneuploid tumors are associated with a higher recurrence rate and decreased disease-free survival than their diploid counterparts. That this difference was not statistically significant for lesions 1.5–2.9 mm thick is due to the relatively small numbers of patients in this group.

These findings are strongly suggestive that measuring DNA content can significantly contribute to assessing the prognosis of a given melanoma and that study of paraffin-embedded tissue can allow evaluation of previously inaccessible thin melanomas. However, there are several limitations associated with the present study. First, the percentage of aneuploid tumors relative to the entire study population is low (22%) compared with the 54–85% incidence reported elsewhere.[31,41,42] We believe this discrepancy is largely due to differences in the patient populations studied, as we have described in detail in an earlier report.[17] Unlike previous series, our population consisted entirely of primary Stage 1 lesions, many of which were also low microstage (thickness). However, the possibility exists that we may have underdetected aneuploidy on these small samples of paraffin-embedded material. This issue will only be resolved with improved technology for ploidy determination in paraffin-embedded material because other workable approaches to studying DNA abnormalities in large numbers of small, thin melanomas do not yet exist to our knowledge. Second, the tumors were collected from three institutions over a 20-year period and the influence of variable treatment approaches, as a function of both the institution of origin and the passage of time, on clinical outcome, cannot be quantified.

Regardless of the limitations of this study, the likelihood that analytic techniques will be of benefit in the assessment of cutaneous melanomas appears established.

Acknowledgments

We would like to acknowledge the valuable assistance of Janet M. Wolter, M.D., Michele Parker, M.S., R.N., and Ronald S. Weinstein, M.D. Dr. Ronald Alexander and James Elder provided material from 90 patients, and Dr. Charles Balch provided clinical data on the patients as well as valuable advice.

Effect of Moderate Hypothermia in the Treatment of Canine Hemorrhagic Shock

DAN M. MEYER, M.D., and JURETA W. HORTON, PH.D.

This study evaluated a possible protective and therapeutic effect of moderate hypothermia in the treatment of severe hemorrhagic shock. A modified Wiggers shock preparation was used. Normothermic dogs (Group I, N = 6) were maintained at normal body temperature throughout hemorrhagic shock and resuscitation. In Group II, hypothermia was initiated after 15 minutes of hemorrhagic shock (N = 12) and maintained for 60 minutes after fluid resuscitation. Animals were then rewarmed with Group IIA (N = 7) receiving sodium bicarbonate to correct acidosis, while Group IIB (N = 5) did not; all dogs were studied for an additional 120 minutes. During shock heart rate was lower in both hypothermic groups (IIA and IIB) compared to normothermic dogs (85.0 ± 3.9, 77.7 ± 4.6 *vs.* 136.7 ± 4.2, respectively, $p < 0.05$), while +dP/dt (mmHg/s) remained stable in all dogs. Furthermore, pH was lower in the hypothermic (Groups IIA and IIB) compared to normothermic animals at this time period (Group IIA: 7.19 ± 0.02, Group IIB: 7.13 ± 0.02 *vs.* Group I: 7.24 ± 0.02). Arterial pCO_2 was higher in the hypothermic hemorrhagic shock Groups IIA and IIB compared to normothermic group (34.5 ± 2.2, 37.4 ± 2.2 *vs.* 20.3 ± 20, 3 ± 2.0, $p < 0.05$) due to hypothermia-depressed respiration. A higher myocardial O_2 consumption and a negative myocardial lactate balance occurred in the normothermic animals during hemorrhagic shock. After resuscitation and rewarming, stroke volume (mL/beat) and cardiac output (L/min) were lower in hypothermic animals with persistent acid–base derangements (12.6 ± 2.5, 1.3 ± 3.0, respectively) compared to hypothermic dogs with acid–base correction (20.1 ± 3.3, 2.2 ± 0.3) and normothermic dogs (24.6 ± 3.0, 3.0 ± 0.3, $p < 0.05$), while myocardial O_2 extraction and myocardial lactate production were higher. Results suggest hypothermia decreases the metabolic needs and maintains myocardial contractile function in hemorrhagic shock. Hypothermia may have a beneficial effect and, with normalization of acid–base balance, a therapeutic role in hemorrhagic shock.

THE EFFECT of hypothermia in the treatment of hemorrhagic shock is controversial. Hypothermia, which decreases total body oxygen consumption,[1] has been shown to increase survival rate[2] and prolong the period of tolerance to severe hemorrhage.[3] The disciplines of neurologic and cardiovascular surgery have utilized hypothermia during surgical procedures and described a protective effect.[4,5] However, the therapeutic value of hypothermia in the shock state is much less clear, and conflicting data regarding any beneficial effect of hypothermia have been attributed to differences in experimental preparation, type and degree of shock produced, as well as the level of hypothermia achieved.[6-9] The present study was designed to evaluate the effect of moderate hypothermia on cardiovascular function, regional blood flow, and oxygen consumption in hypothermia plus severe hemorrhagic shock.

Materials and Methods

Hemodynamic Studies

Eighteen mongrel dogs of either sex, weighing between 16 and 28 kg were included in the study. Anesthesia was induced with sodium thiopental (15 mg/kg, I.V.) and maintained with alpha-chloralose in polyethylene glycol 200 (50 mg/kg, I.V.). Dogs were intubated and allowed to breathe room air spontaneously. Polyethylene catheters were placed in the femoral and brachial arteries and advanced into the descending aorta for removal of blood during hemorrhage, blood sampling, and measuring arterial blood pressure. Arterial blood pressure was monitored with a strain gauge transducer (Statham, Model 231D). Polyethylene femoral venous catheters were also placed and advanced into the inferior vena cava for administration of fluids, drugs, and the return of shed blood. Left ventricular pressure was obtained from a Millar catheter (Millar, Inc., Houston,

Submitted for publication: October 8, 1987.

Texas) inserted through the left internal carotid artery. The Millar transducer was initially zeroed and calibrated in a 37 C water bath (Millar, Inc., Model PC470). A polyethylene catheter was also placed into the coronary sinus through the right internal jugular vein, and a Swan-Ganz catheter was placed into the pulmonary outflow tract, through the left internal jugular vein. These three catheters were placed under the aid of fluoroscopy. A derivative computer (Hewlett-Packard, Model 8814A, Richardson, TX) provided continuous monitoring of maximal rate of left ventricular pressure rise (+dP/dt) and fall (−dP/dt). All hemodynamic parameters were recorded on a Mingograf recorder (Siemens, Model 81, Grand Prairie, TX). Cardiac output was determined in duplicate by the dye dilution technique using indocyanine green. In addition to the vascular catheters, four peritoneal dialysis catheters (Travenol Laboratories, Model 2C4105, Deerfield, IL) were placed in the ventral midline region of the animals. These catheters were introduced intraperitoneally via an open technique. This involved visualization of the parietal peritoneum before placement of the four catheters. All dogs were heparinized (100 units/kg) immediately before insertion of the left ventricular catheter (Fig. 1).

Coronary Blood Flow and Myocardial Oxygen Consumption

Regional blood flow was measured by injection of 1 × 10^6 microspheres (15 ± 3 μm) as a bolus into the left ventricle (3M Company, St. Paul, MN; New England Nuclear, Boston, MA). Immediately before each injection, the vial containing the microsphere (^{113}SN, ^{57}Co, ^{46}SC, ^{95}Nb, ^{125}I, and ^{85}Sr) was mixed by vortex agitation. One milliliter of the microsphere suspension was rapidly injected into the left ventricle and the catheter was immediately flushed with 10 mL of saline solution. This volume of microsphere-containing suspension allowed for an adequate number of microspheres to be administered (at least 400 microspheres/tissue sample) and ensured accurate measurement of blood flow. Simultaneous with the injection of microspheres and continuing for 120 seconds, reference blood samples were obtained from the femoral arteries, each at a rate of 10 mL/min (Holter pump, Model 911, Critikon, Inc., Tampa, FL). At the end of each experiment, the animals were killed by an overdose of barbiturates. The heart was removed and placed into a buffered formalin solution. The myocardial tissue and reference blood samples were counted for 5 minutes in a multichannel gamma scintillation spectrometer (Packard, Model 5320, Legona Hills, CA). The remaining internal organs were treated similarly. For each set of samples, vials containing small aliquots of each microsphere were used to determine the energy level setting on the scintillation counter to be used.

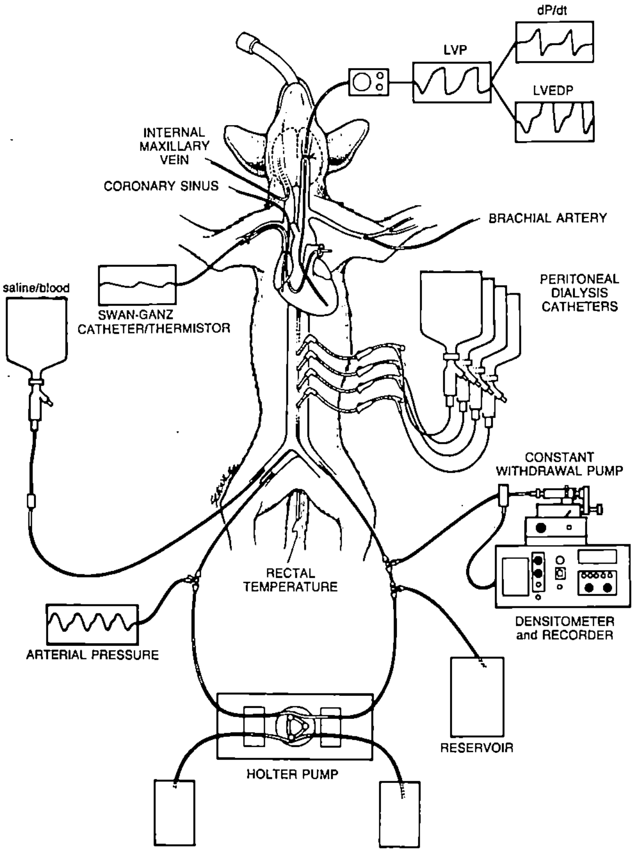

FIG. 1. Experimental model.

From the standards of each microsphere used to set the energy level and the actual sample containing the highest count of microspheres injected, the cross-talk fraction or overlap of gamma energies was calculated for each of the microspheres. The contribution of this overlap of gamma energies of each microsphere was then subtracted and a nuclide reference factor (mL/min/counts) calculated for each microsphere. For each of the samples, the background counts were subtracted and the counts for each isotope were multiplied by the nuclide reference factor in order to obtain a mean blood flow rate.

Hemorrhage, Hypothermia, and Resuscitation

All dogs were given 10 mL/kg of 0.9% normal saline solution during instrumentation. Animals were then allowed to stabilize for 30 minutes. Baseline blood pressure, mean arterial pressure, heart rate, +dP/dt, −dP/dt, left ventricular pressure, left ventricular end-diastolic pressure, pulmonary capillary wedge pressure, pulmonary artery pressure, respiratory rate, urinary output, core body temperature, and rectal (body) temperature (via the Swan-Ganz [American Edwards Laboratories, Santa Ana, CA] catheter thermistor and a rectal temperature probe, respectively) were measured and a micro-

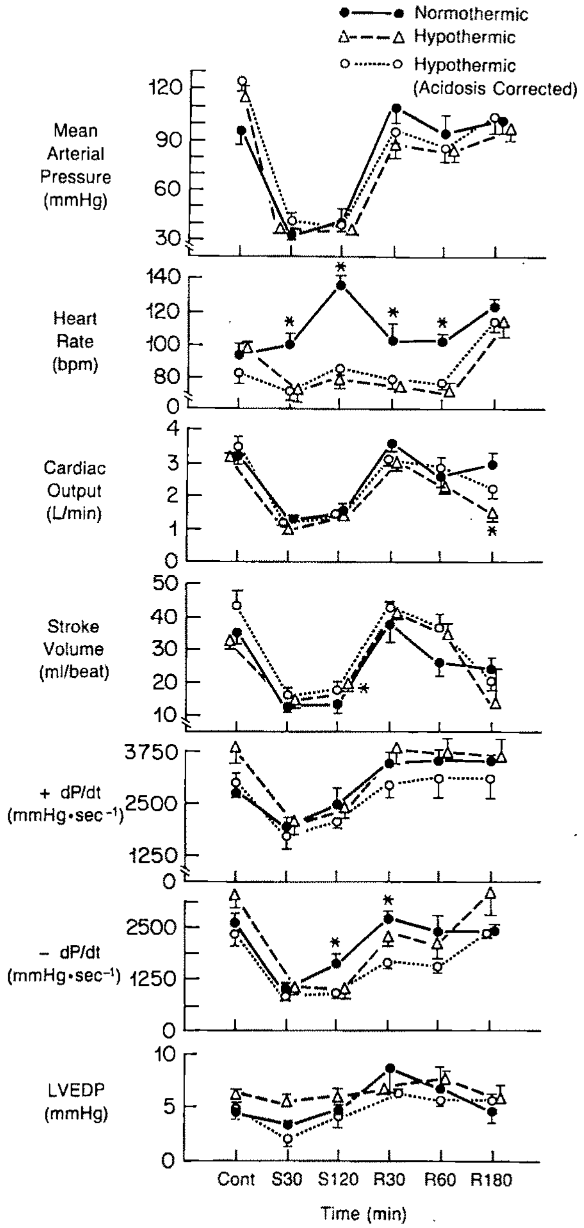

FIG. 2. Hemodynamic and left ventricular contractile response to hemorrhagic shock and hypothermia. All values are given as mean ± SEM. *Significant difference between groups, $p < 0.05$.

sphere was injected for measurement of baseline blood flows. The right femoral artery cannula was then connected to an air-pressure–regulated blood reservoir, and shock was induced, with the end-point being a mean arterial pressure of 35 mmHg. Animals were then divided into three groups. In Group I, six dogs were hemorrhaged over 5 minutes. After 2 hours of controlled hemorrhagic shock, shed blood was returned to all dogs through a micropore filter (Fenwal Laboratories, Model 4C2423, Division of Travenal, Deerfield, IL) via the femoral vein cannula and lactated Ringer's solution was infused (50 mL/kg), with no hypothermic intervention.

In Group II shock was established as described for Group I. Hypothermia was achieved after 5 minutes of hemorrhagic shock by instilling iced normal saline at 4 C into the peritoneal cavity via the peritoneal dialysis catheters. The iced saline was then circulated using a siphon exchange effect to remove the fluid, until a target temperature of 33 C was reached. All measurements, including microsphere flow determinations, were recorded after 30 and 120 minutes of hemorrhagic shock. Two hours after the onset of shock, dogs were resuscitated as described for Group I, and hypothermia was maintained. All measurements were again recorded at 30, 60, and 180 minutes after resuscitation. The animals in Group II were rewarmed 60 minutes after resuscitation, using warmed normal saline solution at 44 C infused through the peritoneal dialysis catheters; then the animals were divided into two subgroups for assessment of hypothermia on acid–base derangements. In Group IIA (N = 7) acidosis was corrected during rewarming using IV sodium bicarbonate titrated to an arterial pH of greater than 7.25. In Group IIB (N = 5) acidosis remained uncorrected. During rewarming animals were given lactated Ringer's solution at a rate of 10 mL/kg/h to keep mean arterial pressure and heart rate at approximate baseline levels.

Statistical Analysis

Results were expressed as mean ± SE. Statistical analysis included an ANOVA and repeated measure procedure (Newman-Keuls). All values were considered significant at $p < 0.05$. All hemodynamic and flow parameters changed significantly from baseline with shock ($p < 0.05$).

Results

Cardiovascular Response

Before shock cardiocirculatory function and metabolic status were similar in all dogs. Hemorrhage to a mean arterial blood pressure of 30 mmHg reduced cardiac output, stroke volume, ±dP/dt, stroke work, and regional blood flows to a similar extent in all animals. Early shock (S15) was characterized by acid–base derangements that included a fall in arterial pH and bicarbonate as well as a rise in circulating lactate levels. Throughout shock, heart rate and respiratory rate were significantly lower in all hypothermic compared to normothermic dogs while mean arterial blood pressure, cardiac output, and left ventricular end-diastolic pressure were similar in the three groups (Fig. 2). Baseline peripheral vascular resistance (mean arterial blood pressure divided by cardiac output and multiplied by 80 to convert units to dyne × s × cm^{-5}) was similar in all dogs (normothermic: 2480 ± 280; hypothermic Group IIA: 2640 ± 244; hypothermic Group IIB: 2880 ± 480). After

120 minutes of shock, the rate of left ventricular relaxation (−dP/dt) was significantly lower in hypothermic Groups IIA and IIB compared to the normothermic shock groups (875 ± 150, 975 ± 200 *vs.* 1550 ± 275 mmHg/s, $p < 0.05$), while the rate of left ventricular pressure rise (+dP/dt), cardiac output, LVEDP, and stroke work were comparable in the three groups at this time. After 2 hours shock, stroke volume was significantly higher ($p < 0.05$) and heart rate lower ($p < 0.05$) in hypothermic compared to normothermic shock dogs.

After fluid resuscitation, but before rewarming, the heart rate remained lower in hypothermic dogs (Group IIA: 75.7 ± 3.8; Group IIB: 70.0 ± 5.4) compared to normothermic dogs (100 ± 4.5 beats/min, $p < 0.05$), while mean arterial blood pressure, peripheral vascular resistance, left ventricular pressure, left ventricular end-diastolic pressure, +dP/dt, and −dP/dt were similar in all dogs during this time. Thirty minutes after fluid resuscitation, cardiac output returned to baseline values but was significantly lower in hypothermic than in the normothermic dogs ($p < 0.05$). Rewarming the hypothermic animals after volume replacement increased cardiac output to a level comparable to that observed in the normothermic animals. Peripheral vascular resistance was higher in all hypothermic compared to normothermic dogs after volume replacement (Group IIA: 3224 ± 240; Group IIB: 3664 ± 280; Normothermic: 2768 ± 300 dyne × s × cm^{-5}; $p < 0.05$). Peripheral blood flows were comparable in all dogs throughout the experimental period, regardless of body temperature (Fig. 3). Adrenal blood flow tended to be lower in both hypothermic groups compared to normothermic dogs after resuscitation, but this difference did not achieve statistical significance.

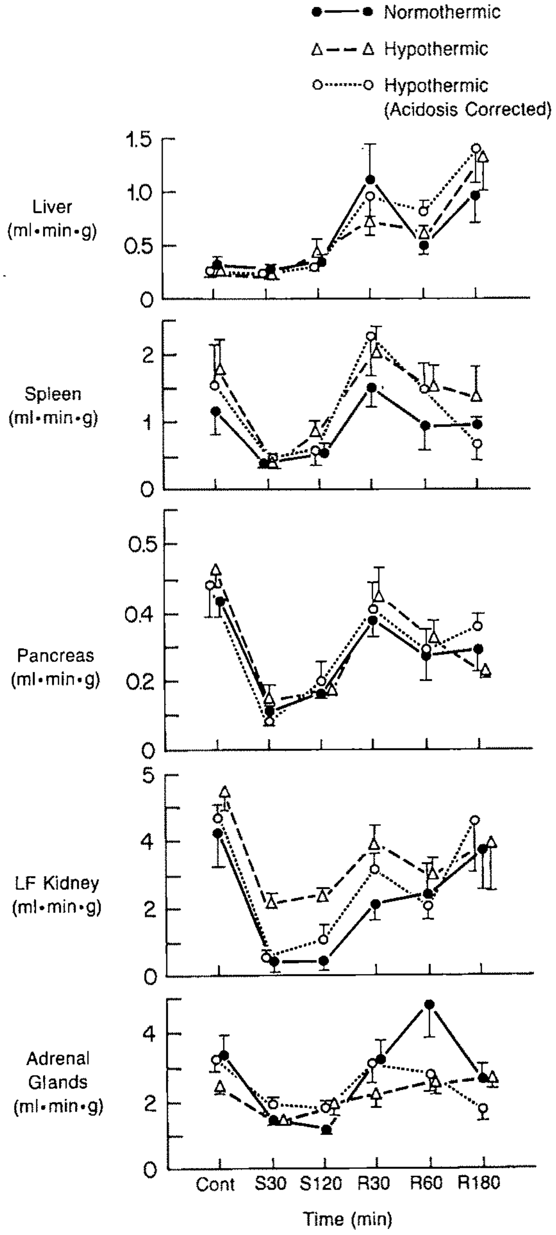

FIG. 3. Changes in regional blood flow during hemorrhagic shock and hypothermia.

Myocardial Blood Flow and Oxygen Metabolism

Baseline myocardial blood flow, myocardial oxygen extraction, myocardial oxygen delivery, and circulating lactate levels were similar in all dogs (Fig. 4). In addition, endocardial-epicardial ratios were similar in all dogs before hemorrhage (normothermic: 1.12 ± 0.06; hypothermic Group IIA: 1.16 ± 0.04, hypothermic Group IIB: 1.09 ± 0.06). There was, however, a tendency toward a higher myocardial oxygen consumption in the normothermic compared to hypothermic shock dogs before shock, but these differences did not achieve statistical difference. Total body oxygen consumption and myocardial oxygen extraction fell during hemorrhagic shock but to a significantly greater extent in the hypothermic dogs, $p < 0.05$. In early shock, myocardial oxygen delivery and myocardial oxygen consumption decreased to a similar extent in all dogs, regardless of body temperature. In late shock endocardial-epicardial flow ratios in normothermic dogs fell significantly from baseline values of 1.12 ± 0.06 to 0.87 ± 0.03, $p < 0.05$. After 2 hours sustained shock, subendocardial perfusion in the hypothermic dogs was unchanged from baseline values and significantly higher in the hypothermic (Group IIA: 1.07 ± 0.05; Group IIB: 0.98 ± 0.04) compared to normothermic dogs (0.87 ± 0.03, $p < 0.05$). In late shock (S120), myocardial blood flow and myocardial oxygen delivery increased to 87% of baseline values in the normothermic shock group but remained significantly lower in hypothermic dogs ($p < 0.05$). After fluid resuscitation, myocardial blood flow and myocardial oxygen delivery increased and myocardial oxygen extraction fell to a similar extent in all dogs. After re-

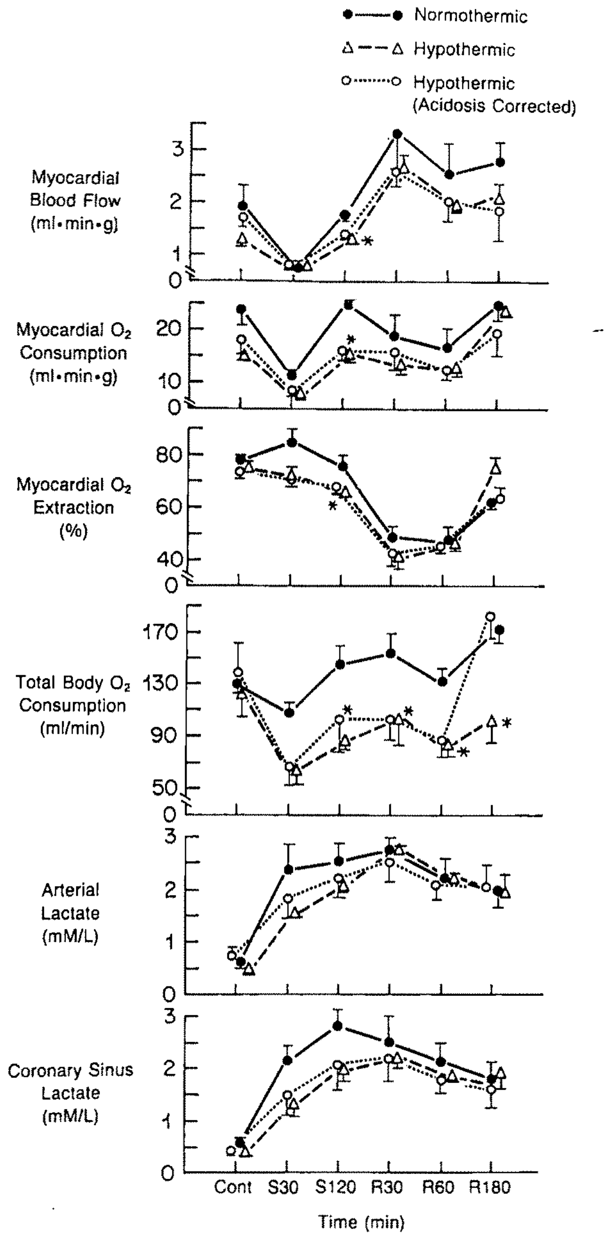

FIG. 4. Coronary blood flow, myocardial oxygen consumption and extraction, total body oxygen consumption, and arterial and coronary sinus lactate levels.

warming (R180) all indices of myocardial perfusion and myocardial oxygen metabolism were similar in the three groups, regardless of body temperature. However, total body oxygen consumption remained significantly lower in those dogs with persistent acid-based derangements ($p < 0.05$).

Acid-Base Status

Baseline measurements of acid-base balance as well as respiratory rate were similar in all dogs (Fig. 5). Hemorrhagic shock caused significant acidosis, as indicated by a progressive rise in circulating lactate levels and a progressive fall in arterial pH and bicarbonate level. While there was considerable variability in arterial pO_2 within groups, the changes from baseline values did not

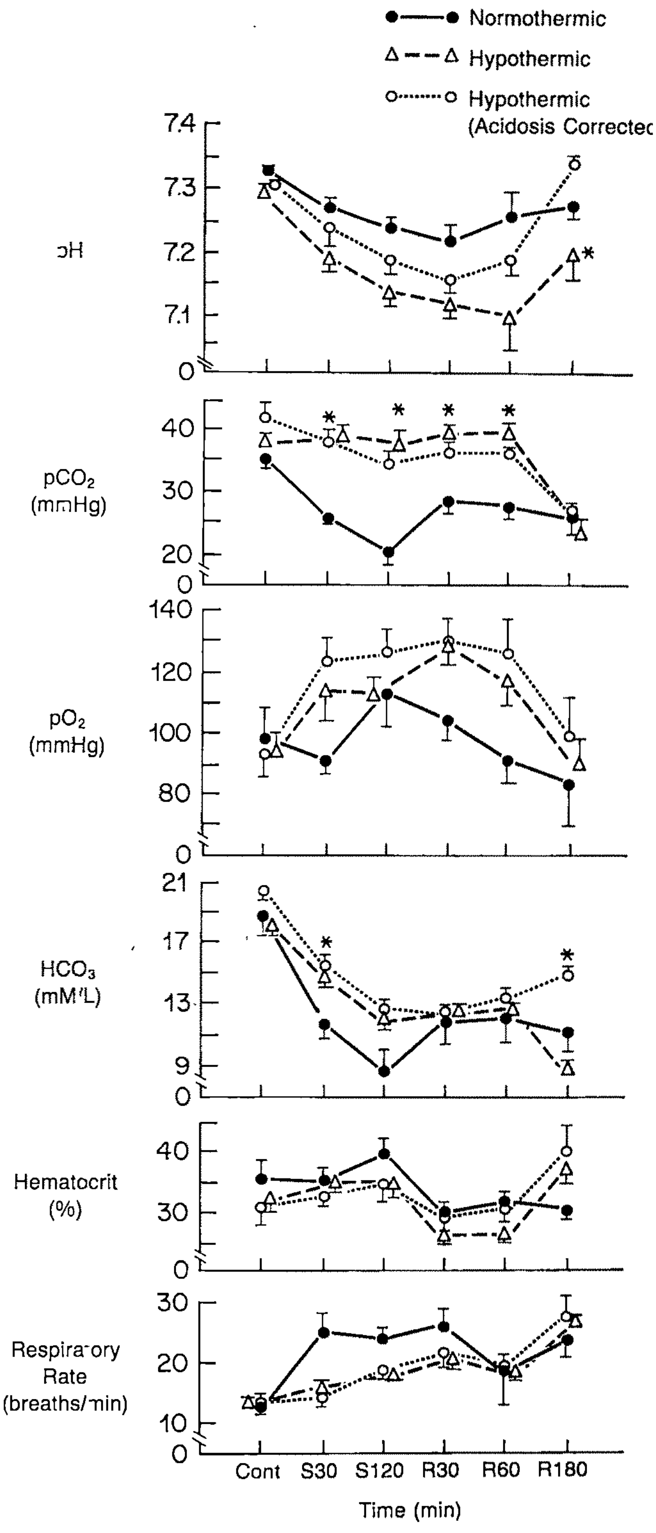

FIG. 5. Acid-base status in hemorrhagic shock and hypothermia.

achieve statistical significance. Hematocrit remained unchanged during hemorrhagic shock in all dogs, and there was similar hemodilution in all groups after fluid resuscitation. Normothermic shock caused a significant tachypnea ($p < 0.05$), producing a fall in arterial pCO_2. In contrast, respiratory rate remained unchanged from baseline values in hypothermic animals, causing arterial pCO_2 to be significantly higher in these dogs throughout hypothermic shock. Immediately after fluid resuscitation (R30), respiratory rate remained significantly lower and arterial pCO_2 higher in all hypothermic compared to normothermic dogs ($p < 0.05$). Sixty minutes after resuscitation, respiratory rates were similar in all groups, and this similarity persisted throughout the experimental study. Acid–base derangements persisted in the hypothermic dogs not given bicarbonate as indicated by a lower arterial pH and serum bicarbonate.

Discussion

Our data showed that moderate hypothermia in severe hemorrhagic shock reduced the metabolic requirements of the heart while maintaining cardiovascular function and myocardial perfusion. The cardiovascular responses to normothermic shock in this study were consistent with those reported previously by this laboratory and by other investigators.[10] These changes included tachycardia, a fall in preload and afterload, impaired left ventricular function, reduced peripheral perfusion, and increased respiratory rate. With crystalloid resuscitation, all cardiocirculatory parameters returned toward baseline values. The induction of hypothermia during hemorrhagic shock produced a significant bradycardia and prevented the tachypnea that is typical of normothermic shock. In addition, hypothermia enhanced left ventricular performance in late shock as indicated by a stable cardiac output and a higher stroke volume despite an unchanged LVEDP and a significant bradycardia. Increased left ventricular ejection, accompanied by no change in cardiac filling or fiber length indicates a positive inotropic response to hypothermia. Our data support the findings of Templeton et al. who showed that hypothermia prolonged the time course of cardiac contraction and increased total tension development.[11] Our data are consistent with studies by Monroe who reported increased ventricular work at a constant LVEDP.[12] Furthermore, Monroe showed no change in left ventricular pressure volume relationships when body temperature was below normal. These data contradict studies by Templeton et al. who described marked alterations in myocardial mechanical properties with changes in temperature, showing that stiffness was inversely proportional to temperature.[11]

Resuscitation improved hemodynamic function in all dogs, but bradycardia and a lower respiratory rate persisted in the hypothermic animals. Thirty minutes after rewarming, cardiovascular function was not significantly different from baseline values, regardless of a previous episode of hypothermia.

The finding of a higher peripheral vascular resistance in the hypothermic dogs 180 minutes after volume replacement and 2 hours after rewarming was an interesting and unexpected finding. Hypothermia may have a prolonged constrictive effect on the peripheral arterial sphincters, an effect not evident earlier in the experiment because of the inherent inaccuracy of peripheral vascular resistance determination during the use of the pressure-controlled hemorrhage reservoir. The authors considered the possibility that a primary fluid deficit may have existed, but this proved unlikely in light of a normal cardiac filling pressure or normal left ventricular end-diastolic pressure. Finally, rewarming likely promoted a massive vasodilatation of the peripheral vascular beds, followed by a vasoconstrictive effort in order to maintain central blood pressure. However, these explanations are purely speculative, and the specific effects of hypothermia on the peripheral vasculature warrants further study.

Myocardial blood flow and oxygen metabolism were comparable in all dogs during early shock, regardless of body temperature. In late hemorrhagic shock, coronary blood flow increased in normothermic dogs, likely due to sympathoadrenal activation, tachycardia, and increased metabolic needs of the myocardium. The lower coronary blood flow in late hemorrhagic shock in the hypothermic dogs supports previous reports that hypothermia decreased myocardial oxygen metabolism and reduced myocardial blood flow.[13,14] Other studies of severe hypothermia (body temperature at 21 C) showed a decrease in cardiac output while subendocardial perfusion was preserved.[15] Studies of normovolemic hypothermia with cardiac output held steady showed a fall in cardiac oxygen consumption and heart rate, an unchanged blood pressure, and a significant increase in the per cent of cardiac output to the heart.[16] Similarly, Sabiston et al. reported that the per cent of cardiac output delivered to the heart increased significantly in hypothermic dogs, attributing the selective increase in coronary flow to a direct effect of temperature on the myocardial smooth muscle and active vasodilitation of the coronary vasculature.[17]

Our data indicate that hypothermia in hemorrhagic shock reduced myocardial oxygen metabolism as indicated by a bradycardia and a lower myocardial oxygen extraction in hypothermic compared to normothermic shock. It was of interest that myocardial oxygen extraction was lower during shock in the hypothermic dogs, despite a higher stroke volume in this group. The metabolic needs of the myocardium are dictated by both contractile function as well as heart rate. However, the pronounced bradycardia in the hypothermic shock apparently overwhelmed the moderate increases in contractile function, decreasing myocardial oxygen requirements. While total myocardial blood flow was lower in late hypothermic shock, there was no evidence of subendocardial ischemia since endocardial epicardial flow ratios remained unchanged from baseline measurements. Our data support the concept that myocardial oxygen requirements are the primary regulator of coronary blood flow, overwhelming any direct effects of temperature on the coronary vasculature.

The acid-base changes observed in normothermic shock are consistent with those previously reported by our laboratory and others. In shock, progressive metabolic acidosis was accompanied by a respiratory alkalosis, preventing excess arterial pH changes despite severe hemorrhagic shock. A metabolic acidosis without respiratory compensation occurred in the hypothermic groups as indicated by the higher pCO_2 and unchanged serum bicarbonate, lower respiratory rate, and higher circulating lactate levels. Our finding of lower coronary sinus and arterial lactate levels in the hypothermic dogs supports a previous study by Shipp et al. who demonstrated that hypothermia reduced lactate formation in the perfused heart.[18] To our knowledge, while no studies have specifically focused on the acid-base status in our model of hemorrhagic shock followed by hypothermia, a large body of literature describes the effect of pH on the hypothermic heart. These previous studies have shown that moderate variations of the extracellular acid-base environment during hypothermia do not impair myocardial function or oxygen demand ratios.[19] While coronary blood flow and myocardial oxygen delivery were lower in late hypothermic compared to late normothermic shock, it is likely that the leftward shift of the oxygen disassociation curve preserved myocardial oxygen consumption and protected cardiac function under conditions of decreased oxygen supply.[20] These data are consistent with previous reports that hypothermia modifies all determinants of oxygen supply but tissue hypoxia does not occur.[19] Several investigators have proposed that intracellular buffering mechanisms compensate for moderate variations in the extracellular pH and that the depressive effects of acid-base disorders on myocardial contractility are related to severe changes in intracellular pH which overwhelm intracellular buffering mechanisms.[20,21] Studies by Poole-Wilson and Langer,[21] using a hypothermic isolated perfused papillary muscle preparation, observed that acidosis was associated with the rapid fall in myocardial tension development while alkaline pH preserved contractile function in a hypothermic preparation. Becker et al.[22] also showed improved cardiac function in hypothermia if pH was adjusted to an alkaline range, attributing enhanced cardiac performance during hypothermia with pH correction to a more ideal biochemical environment for continued aerobic metabolism. It is likely that the inotropic effect of hypothermia in our study would have been significantly enhanced if acid-based correction and ventilatory support had been instituted during the shock period. This hypothesis is supported by the significant increase in cardiac output with acid-base correction in the hypothermic dogs.

Intracellular acidosis may explain the elevated hematocrit at the end of the experimental period. An appropriate pH is necessary to stabilize the Gibbs-Donnan ratio and red blood cell volume while intracellular acidosis leads to cellular swelling.[23] Other possibilities include fluid deficits, increased viscosity, or decreased blood volume secondary to hypothermia itself.[16] Furthermore, an increased circulating catecholamine level secondary to hypothermia may promote splenic contraction and, therefore, hemoconcentration as seen in our experiment.[24] The cause is likely multifactorial.

While the authors acknowledge several problems inherent in studying hemorrhagic shock complicated by hypothermia, this situation is a difficult clinical issue that needs to be addressed. First, it is difficult to separate the physiologic response to hypothermia from the responses to hemorrhagic shock. Moreover, it is likely the hypothermia-mediated increases in ventricular stiffness[1] impair accurate measurement of contractile changes that relate stroke volume to left ventricular filling pressures. Also, in our model difficulties arose in distinguishing the effects of shock-induced acidosis from the effects of hypothermia-induced acidosis. Are these additive detriments or mutually exclusive insults? Could the combination of increased contractile function and decreased peripheral metabolic rate present in the hypothermic shock portend a lesser degree of coagulopathy than that which occurs in normothermic shock? In summary, our data suggest that hypothermia reduces metabolic requirements during hemorrhagic shock while maintaining cardiovascular function and adequate myocardial oxygen delivery. The application of these findings combined with critical attention to the optimal acid-base balance may suggest a potential role of hypothermia in the treatment of severe hemorrhagic shock.

Septic Necrosis of the Midline Wound in Postoperative Peritonitis

Successful Management by Debridement, Myocutaneous Advancement, and Primary Skin Closure

ÉTIENNE LÉVY, M.D.,[*] DONALD L. PALMER, M.D.,[†] PASCAL FRILEUX, M.D.,[‡] LAURENT HANNOUN, M.D.,[§]
BERNARD NORDLINGER, M.D.,[§] EMMANUEL TIRET, M.D.,[||] JIRI HONIGER, M.D.,[¶] and ROLLAND PARC, M.D.[#]

Wound management following laparotomy for postoperative peritonitis and varying degrees of parietal necrosis remains a challenging and controversial problem. Because maintained peritoneal integrity and primary wound closure offer the best opportunity for survival, an original technique involving bilateral incisions to relax skin and rectus fascia is proposed. This technique permits medial myocutaneous advancement and primary tension-free skin closure of midline laparotomy incisions. Sixty-nine patients with severe postoperative peritonitis were treated according from 1980 through 1985. Nine of these patients died of advanced multiple organ failure soon after referral, and eight more died after prolonged treatment. Fourteen patients had one or more reoperations for complications. Only nine wound failures resulted, including five eviscerations and four wound infections followed by progressive dehiscence. The bilateral relaxing incisions healed secondarily without complication. Survivors developed midline wound hernia; ten of the 52 surviving patients have had these repaired. This method of primary closure is safe when performed in conjunction with rigorous surgical care of intraperitoneal infection and may enhance survival. We recommend the technique to surgeons who treat severe postoperative peritonitis and septic necrosis of midline laparotomy wounds.

CLOSURE of the abdominal wall adds to the already formidable challenge facing the surgeon when parietal necrosis and dehiscence or evisceration complicate severe postoperative peritonitis. Because primary closure under tension in these critically ill patients often fails, alternative methods of abdominal closure have been proposed. These techniques include open wound management with delayed closure or grafting; prosthetic fascial closure with Silastic® sheeting (Dow Corning Corporation Medical Products, Midland, MI); Marlex® (C. R. Bard, Billerica, MA); polypropylene or Vicryl® mesh (Ethicon, Somerville, NJ); and more complex closures using pedicled or rotation flaps. Although these methods have been performed safely, certain disadvantages inherent in each technique require departure from the ideal: primary tension-free parietal closure without use of prosthetic material.

Achievement of this ideal implies satisfactory treatment of the underlying problem. Residual septic foci and enteric fistula would defer convalescence and probably contribute to a higher mortality rate in these seriously compromised patients. Both the incidence of complications and of early reoperations directly related to the technique should be low. Multiple procedures prolong recovery and add risks; ideally, staged closure, removal of prosthetic material, grafting, or repair of incisional hernia would be avoided.

Since 1965 the Intensive Care Unit of the Department of Surgery at Hôpital Saint-Antoine, Paris, has been

dedicated to managing severe septic abdominal conditions and has become an international referral center, admitting patients from France, Western Europe, and Africa. From 1970 through 1985, we managed 590 cases of postoperative peritonitis. We use the term postoperative peritonitis to designate diffuse suppuration (free or multiloculated fluid) or a solitary abscess in direct relation to a high-output gastrointestinal (GI) fistula. The classification excludes solitary abscesses unrelated to a leak in the GI tract. Of the 590 cases of postoperative peritonitis, conventional fascial closure was achieved without excessive tension in 329 (55%). In the remaining cases, we used alternative means of wound management; these techniques have evolved as we sought to lower our rates of complications and repeat operations. From 1970 through 1977, we accomplished closure using through-and-through retention sutures (in 120 cases); otherwise, the abdomen was left open (in 14 cases). In 1977, one of us (E.L.) suggested a method involving lateral skin and fascial relaxation incisions and advancement closure of the midline wound. From 1977 through 1985, we refined this technique of tension-free closure in 127 cases. We report our experience from 1980 through 1985 when the laparotomy wounds of 69 patients (representing 41% of the postoperative peritonitis cases) were managed by bilateral myocutaneous advancement and primary midline skin closure.

Patients and Methods

All patients were seen in the Centre de Chirurgie Digestive of Hôpital Saint-Antoine, Paris, France. The average age was 46 years (range: 13–78 years). Nine patients were older than 70 years. Forty-seven men and twenty-two women were included.

Sixty-eight patients were transferred from other centers, and one patient received initial treatment in our department. Sixty-two patients (90%) had two or more laparotomies before referral. Fourteen (20%) had already had repeat operations in an attempt to control postoperative sepsis and were referred for treatment of persisting infection. In all 69 patients, sepsis complicated a direct procedure on the GI tract (Table 1). In nearly all cases, postoperative peritonitis was caused by technical complications or errors.

Peritonitis was generalized in 62 patients and localized in seven patients. The initial incision was midline in all patients. The abdominal wall had dehisced in 16 patients and was infected or necrotic in 25. Thirty-six patients (52%) presented with three or more of the following severity indicators in addition to the peritonitis: septicemia, shock, adult respiratory distress syndrome (ARDS), renal insufficiency, hepatic insufficiency, thromboembolism, GI hemorrhage, more than three operations, radiotherapy, and substantial parietal necrosis (Table 2). The mean number of severity indicators cumulative by patient was 2.7 ± 1.7. Fourteen patients had associated disease at the time of their first operation. The mean interval between initial operation and reoperation was 17 days and was more than 5 days in 90% of patients.

* Associated disease (N = 14): alcoholism in two, obesity in one, heart disease in five, Crohn's disease in one, and miscellaneous in five patients.

Technique

Our protocol for treatment of postoperative peritonitis[1] was rigorously followed and includes the following elements: (1) complete exposure of the abdominal cavity through a long midline incision. Thorough exploration, (often a lengthy procedure) requires patience, gentleness, and perseverance despite the frequent difficulties encountered during dissection. (2) meticulous peritoneal toilet consisting of aspiration of all blood, ascitic fluid, pus, succus entericus, and feces. Fibrinopurulent exudate was gently debrided using moist gauze; any densely adherent fibrinous material that could not thus be removed was left in situ. Peritoneal lavage with saline was used only to clear debris, and no adjuvant antibacterial substances were instilled into the abdominal cavity. (3) absolute avoidance of intestinal suture or anastomosis. Every breach of intestinal continuity, including those inadvertently created during exploration, is exteri-

orized (N = 38). Stomas thus created are designated salvage in our institution and include loop jejunostomy, loop ileostomy, or loop colostomy if the opening is small; otherwise, end-stoma and mucous fistulas are created.[1] Limited segments of intestine with multiple openings are resected. Any immobile segment such as the duodenum is intubated with silicone catheters held by a pursestring suture, then isolated from the peritoneum by corrugated drains and a Mikulicz pack.[2] Concomitant procedures included salvage enterostomy in 38 patients, intubation and intraluminal irrigation in 25, drainage alone in one, and others in five. (4) active drainage of all dependent areas, accomplished using large perforated silicone catheters surrounded by corrugated rubber drains. These drains were thus routinely placed in subphrenic, subhepatic, and bilateral paracolonic gutters. We provided capillary drainage of the pelvis with Mikulicz packs (Fig. 1).[3] Other Mikulicz packs were placed within large abcess cavities (54 in the pelvic area, 17 in the upper abdomen, and two elsewhere). All Mikulicz packs were left in place for 12–14 days. (5) associated procedures: gastrostomy (N = 36)) or, in the case of gastrectomy or discontinuity of the duodenum, Witzel jejunostomy (N = 16). The gastrostomy was initially used for drainage or hemostatic irrigations, then for enteral nutrition. Jejunostomies were used solely for enteral nutrition.[4] (6) abdominal wall management: bilateral myocutaneous advancement and primary midline skin closure. After debridement, we provided medial mobilization of the margins of the primary incision by making long counterincisions along the lateral edge of the crural arcade from the costal margin superiorly to the suprapubic area inferiorly. The skin and subcutaneum are incised in a curvilinear fashion, and the anterior sheath is incised in a linear manner approximately 1 cm medial to the lateral edge along its entire length (Fig. 2). This is more easily accomplished if the surgeon can palpate the rectus border from within the abdominal cavity. The transverse insertions of the rectus muscle to the anterior sheath must be carefully separated medially as far as feasible. After it is dissected, this unit of anterior sheath, subcutaneum, and skin can then be advanced medially for various distances because the rectus muscle splays as the mobilization proceeds (Fig. 3). If the abdominal wall is supple, 10 cm or more on either side of the midline can be gained to bridge the defect (Fig. 4). If the abdominal wall is indurated, less mobilization is possible.

After excision of any midline necrotic debris, we close the skin using nonabsorbable monofilament mattress sutures. In the few instances where the aponeurotic layer was of good quality and could be approximated without tension, it was closed using running sutures of O-Dexon® (Davis and Geck, Wayne, NJ). The skin and

subcutaneum should be minimally dissected at the margin of the midline incision; otherwise, the subfascial plane could be inadvertently entered, creating a free bipedicled flap (Fig. 5). If a stoma is already present at the time of repeat operation and would interfere with the performance of the relaxation incision, the stoma is relocated. The relaxation incision would then be extended from the stoma site. If the posterior sheath is inadvertently lacerated, we suture the defect and interpose Vicryl mesh between the viscera and the abdominal wall (Fig. 6). These wide relaxation wounds are covered with petrolatum-saturated gauze. Closure by secondary intention proceeds and is usually complete within 5 to 9 weeks (Fig. 7); skin grafts are not necessary.

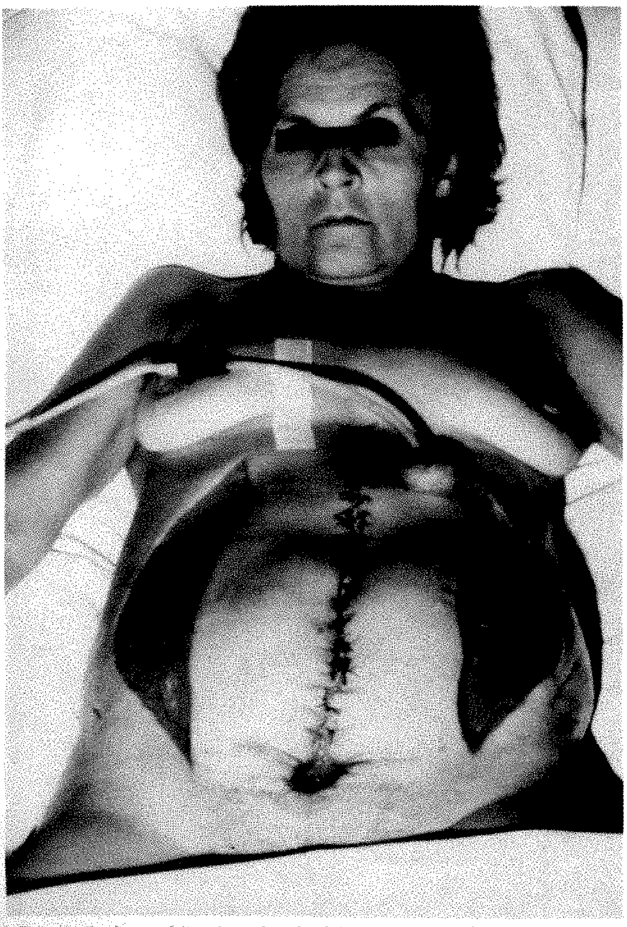

FIG. 4. Patient with relaxation incisions 15 days after operation.

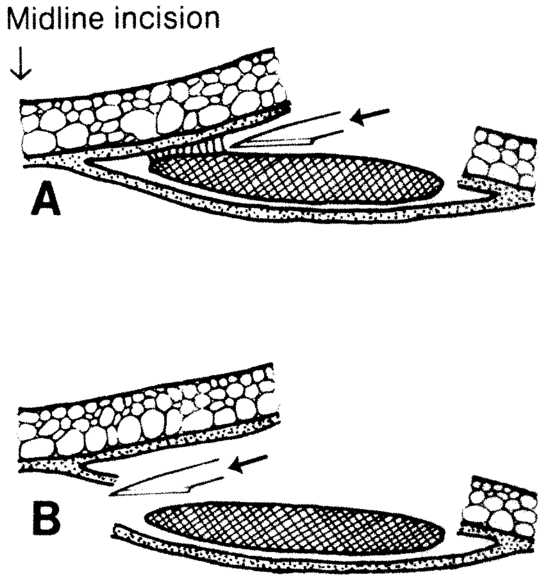

FIGS. 5A and B. *A.* Flap dissection. *B.* Flap dissection extended too far.

Because many of these patients require elevation of stomas or loops of intestine, certain principles have evolved to direct stoma placement. We always create the stomas after completing the relaxation incisions and after debriding the midline wound. We try not to place them within the bed of the relaxation incision, preferring to place them either lateral to the wound or in the isthmus medially; nevertheless, we occasionally must bring the mucous fistula through the rectus muscle and

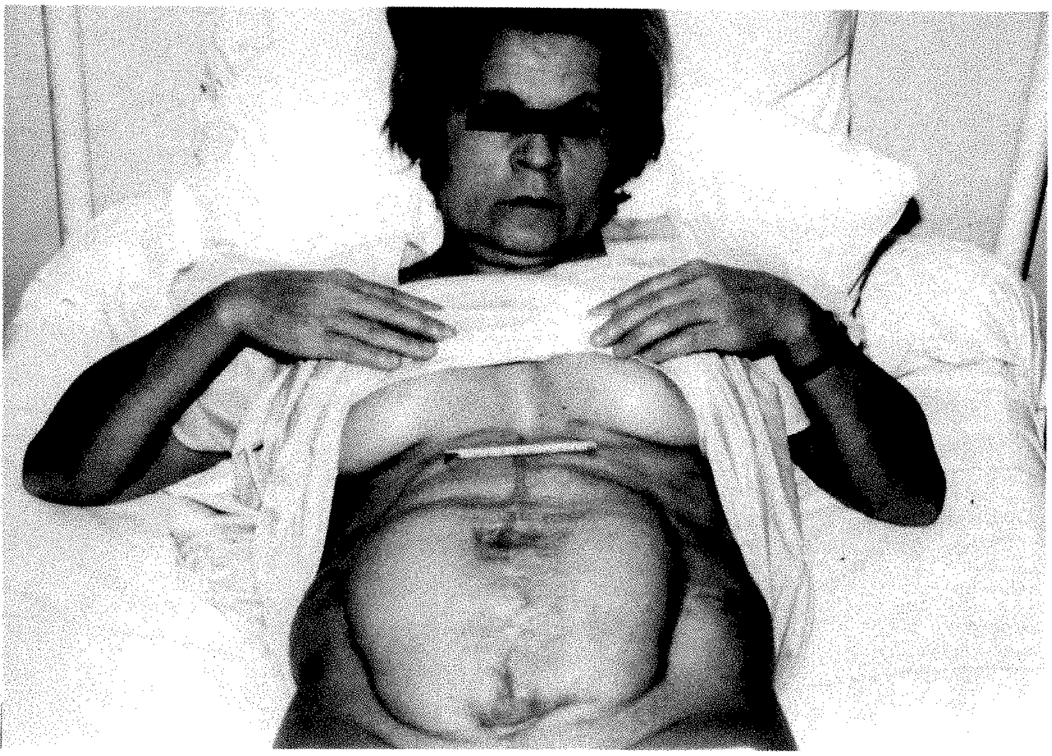

FIG. 7. Photograph of same patient as in Figure 4 shows healing after 9 weeks.

accept the greater complexity of postoperative wound care. We now routinely drain the pelvis with a Mikulicz pack through the inferior extremity of the midline incision.[3] Any other drains are brought through the flanks in a dependent position; these orifices are invariably made lateral to the counterincisions (Fig. 8).

All patients were treated aggressively in the intensive care unit by a team of intensive-care specialists. Blood loss, fluid and electrolyte imbalances, and acid-base disturbances were corrected. We routinely gave prophylaxis against upper GI hemorrhage, thromboembolism, and decubitus.[5,6] Total parenteral nutrition was continued or initiated within 48 hours. Nutritional support was gradually converted to the enteral route whenever effective peristalsis resumed.

Results

Seventeen patients died (24.6%), among whom were nine moribund patients who had been referred in an advanced state of multiple organ failure and who died within 10 days after admission. Mean hospital stay, including repeat hospitalization for reestablishment of GI continuity, was 74 days (range: 1–180 days); for survivors, mean hospital stay was 88 days (range: 20–180 days).

Assisted ventilation was discontinued within 7 days after operation in 53 patients (77%). The remaining 16 patients required prolonged ventilatory support because of respiratory failure.

All patients received total parenteral nutrition until effective peristalsis permitted administration of at least maintenance enteral nutrition. We were able to initiate nasoenteric or jejunostomy-tube feeding at a mean of 5.2 days after operation (range: 4–11 days).

Complications

Thirty-three complications of the initial operation (Table 3) required repeat operation in 14 (20%) patients (Table 4). Of the five eviscerations, two with excessive tension were a consequence of improper application of the technique; three others were due to underlying sepsis. Slowly progressive dehiscence in four cases occurred during the second postoperative week but did not produce visceral complications since granulation tissue covered the loops as the margins separated.

Exposed intestinal fistulas were not observed. All postoperative fistulas occurred in relation to bowel necrosis or necrotizing pancreatitis; none were due to parietal or suture erosion of a superficial intestinal loop.

We observed nine recurrent abscesses (13%). In two, the abscesses spontaneously drained and the patients recovered without further interventions. Five patients had seven reoperations; of these patients, two survived and three died. Two others died without repeat operation, and their abscesses were found at postmortem examination. Etiology of those residual collections was incomplete exploration (abscess left behind) in one case, GI necrosis or perforation in two cases, and no identifi-

able cause in the six remaining cases. Among these six, three were in advanced multiple organ failure—they had more than three severity factors—at the time of referral.

Late Results

One patient died of metastasis from the original cancer, and one died of complications following enterostomy closure. Of the 50 survivors, 35 had received stomas; 30 had GI continuity restored, and five had end ileostomy or colostomy and could not have closure because of local or general contraindications. These elective repeat operations were generally done through the midline laparotomy incision, although a few patients with loop stomas needed only peristomal circumcisions for closure. Only four patients had concomitant repair

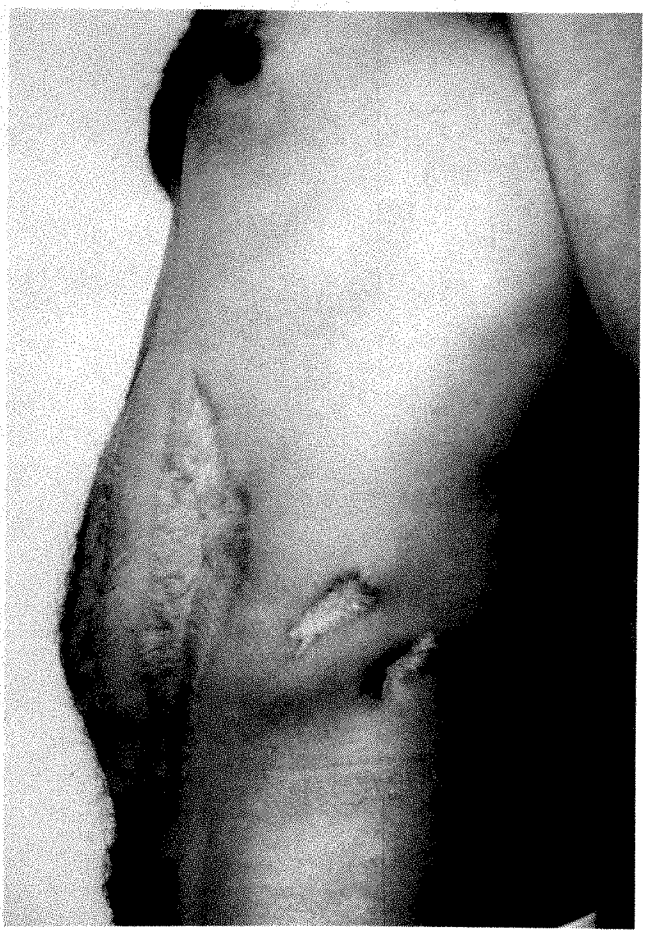

FIG. 9. Photograph shows major incisional hernia.

of midline incisional hernia at the time of restoration of GI continuity. No prosthetic material was used during closure since the margins were simply freshened and approximated. These reoperations were usually delayed for 2–3 months after resolution of the septic event. In all cases, dissection between the advancement flaps and the viscera was easy and bloodless.

Because only the skin is closed during the definitive operation, midline incisional hernia inevitably ensues. This caused major discomfort in 17 patients and aesthetic objections from 31 patients (Fig. 9). No herniation developed through the relaxation incisions. We repaired the incisional hernia in ten patients and needed no prosthetic material. To prevent necrosis of the skin flaps, we avoid dissection between the skin and fascia during herniorrhaphy. In conducting this procedure, we open the midline incision, excise the scar tissue over the relaxation incision, mobilize from the lateral incision by again dissecting between the rectus muscle and anterior sheath, reapproximate the midline fascia, and finally close the skin over the midline and lateral incisions (Fig. 10). If the fascia cannot be approximated without tension, we insert Vicryl mesh beneath the margins and suture it to the posterior aspect of the abdominal wall. Necrosis of a portion or all of the flap complicated three cases; these were simply debrided, and secondary closure proceeded without incident.

Discussion

We have modified our treatment of postoperative peritonitis over the past 10 years as our experience broadened. As a consequence of early recognition of well-established clinical signs,[5] rapid diagnosis followed

by careful application of evolving surgical principles,[1,2,7,8] aggressive intensive care, and nutritional support, overall mortality rate has consistently decreased from 48% before 1980 to 17% from 1980 through 1985.[5]

Even as survival has improved, complexity of the referral cases has increased. Most of our cases are now transferred after failure to control sepsis, malnutrition, and multiple organ failure. Initial assessment documents this by an increase in mean number of severity indicators in our overall series of postoperative peritonitis: 0.8 before 1980, 1.8 from 1980 through 1982, and 1.9 from 1983 through 1985.[5] We now reoperate much earlier; whenever there is any evidence of persistent sepsis, we invariably perform thorough exploration of the abdomen. We avoid anastomosis or simple closure of any disruption of GI continuity and exteriorize mobile bowel as end or loop stomas or intubate and isolate any fixed or retroperitoneal viscus that has been injured or broken down. Problems associated with high-output fistulas or stomas have been solved by reinfusing succus entericus, using specially designed equipment.[9]

Although other workers have reported similar therapeutic approaches to problems of the viscera,[10] widely divergent methods are used to deal with parietal inflammation, necrosis, or defects. The state of the abdominal wall is often disastrous; after debridement of the necrotic areas, aponeurotic closure may be impossible. Moreover, with the edema and distension of the viscera, even the intact abdominal wall often cannot be closed without unacceptable tension. Closure under any tension using such methods as through-and-through retention sutures or sutures over dental rolls aggravates parietal ischemia, may erode the underlying viscera, and risks delayed dehiscence and evisceration (often complicated by exposed fistulas).[11] Given this alternative, many therapeutic techniques have been proposed.

Leaving the abdomen open in an attempt to facilitate drainage of persistent or recurrent collections is an intuitively attractive approach but has little physiologic benefit. The exposed peritoneal surfaces weep large amounts of fluid and often manage to seal septic foci beneath, thus mandating secondary explorations.[12] Protection of the intestinal loops in those cases has been provided by petrolatum-saturated gauze, polyurethane sheets, or moistened gauze,[13–22] and a variation on this therapeutic principle (*i.e.*, planned reexploration) is practiced by those who provide temporary coverage of the viscera by the intact abdominal wall, by prosthetic mesh, or by a zipper (Table 5).[23,24] Routine reexplorations are undertaken at variable intervals, usually 48 hours, and are repeated until gross suppuration resolves.[19,20,23] Improved survival and low incidence of recurrent sepsis reported by those using repeated debridement and lavage is difficult to evaluate since these series include instances of *first-time* peritonitis along with the postoperative peritonitis.[17,19] In series limited to postoperative peritonitis with multiple organ failure, more comparable to our experience at Hôpital Saint-Antoine, significantly improved results have been reported.[13,15,22,23] By carefully applying the surgical principles that have evolved from our experience,[1–4] similar benefit in survival and a low incidence of recurrent sepsis can be obtained without reexploration.

Comparisons among series suffer from difficulties of definition; nevertheless, our rate of recurrent abdominal sepsis is slightly better than that observed in the series advocating repeated reexploration (13% *vs.* an average of 23.5%, Table 4). Prevention of recurrent sepsis depends on the following principles: (1) thorough peritoneal exploration, which minimizes the risk of residual abscesses; (2) diversion of GI injury, leaks, fistulas, or necrosis to prevent suppuration due to recurring leakage; and (3) capillary drainage of the pelvis and large abscess cavities, a technique that we find more effective than using large or multiple suction catheters. Recurrent abscess may occur but should be recognized by ultrasonographic examination[25] or by computed tomography (CT) scan[26] whenever clinical suspicion is high; reexploration or percutaneous drainage may then be more rational. Of the two types of recurrent abscess we report, unexplained and those caused by GI perforation or necrosis, abscess caused by GI perforation or necrosis could not be prevented by a policy of routine reexploration. Rather than a cause, the unexplained abscess may be a manifestation of multiple organ failure (peritoneal failure) since nearly all of ours were found in patients with multiple organ failure at admission. Repeated lavage in this instance could only have a local effect. This hypothesis is illustrated by the example of patients managed by routine reexploration who have persistent gross suppuration until death.[20] The hypothesis is supported by the fact that no technique of reexploration prevents recurrent abscess. Among the practical complications caused by repeated operation are prolonged ventilator dependence, ileus, decubitus, total parenteral nutrition, lengthier stay in the intensive care unit, and high cost. Exposed fistulas complicated a mean of 8% of the cases in the reviewed series (Table 4) regardless of the method used for wound protection. These fistulas are associated with a 40% death rate and require at least a prolonged stay in the intensive care unit.[11] We used the open abdomen technique at Hôpital Saint-Antoine from 1971 through 1977[11] (when conventional closure was impossible) but abandoned it in favor of the method of wound management we report here. The open technique has been rejected by others,[27] including those who initially preferred the approach or restricted it to exceptional cases.[28]

Ogilvie[29] first proposed the use of prosthetic cotton-mesh closure of large abdominal wounds during World War II. Similar management with synthetic materials such as polypropylene and Marlex continues to be reported.[25,30-33] Presence of the mesh minimizes external trauma to the superficial loops, but the rate of exposed fistulas remains high, ranging between 6% and 16%. Recurrence of peritoneal sepsis varies from 15% to 66%.[31,34] Late complications such as mesh extrusion, bowel fistula, and difficulty in mesh removal have led some authors to favor coverage of the defect with split-thickness skin grafts[31] or myocutaneous flaps.[25,31,34]

Levasseur et al.[35] used Vicryl mesh to close the fascia in 17 patients. The material was applied during the first intervention in seven patients and during the initial reoperation in the other ten patients. Two enterocutaneous fistulas and three residual abscesses complicated the method among this group. This material is well tolerated (especially in a septic milieu), does not harm the viscera, and carries no risk of rejection. Although late herniation is inevitable, it may be repaired. Use of Vicryl does not completely prevent development of exposed fistulas. We reserve Vicryl mesh for exceptional cases of massive abdominal wall loss when closure is impossible despite relaxation incisions.

Conclusion

We present a simple, straightforward method of parietal closure: debridement of necrotic tissue, bilateral relaxing incisions, adequate muscular effacement, and tension-free skin closure. Since peritoneal integrity and defenses are maintained, postoperative care is simplified. In contrast to the open technique, fluid losses are minimized, and patients need not be kept in bed with assisted ventilation. Protection of the small bowel permits peristalsis and, therefore, provision of nutrition by the enteral route. Despite the difficulty of comparing series, our confidence in the defense capacity of the peritoneum appears justified; the incidence of residual abscess is scarcely more frequent than that reported with the open method. The late reoperations, which restore GI continuity, are facilitated by primary closure. With the rapid rehabilitation that accompanies clearance of all septic foci, earlier stoma closure and incisional hernia repair can proceed. Dissection beneath intact skin (instead of skin grafts) is simpler and safer.

The technique described should be reserved for the most serious cases of peritonitis. Parietal loss is an essential criterion; however, closure may not be possible in patients with distended and thickened bowels, even in the absence of parietal defects. The greater the number of previous operations and delay between the first operation and initial intervention, the more likely we are to use this method of wound management.

Surgery for Cerebrovascular Disease. Wesley S. Moore. 957 pp. New York: Churchill Livingstone. 1987. $150.00.

THE TEXTBOOK ENTITLED, *Surgery for Cerebrovascular Disease,* edited by Dr. Wesley S. Moore is a compilation of a large number of noted physicians with expertise in the management of cerebrovascular disease. As stated in the preface of the book, Dr. Moore has accumulated authors from each of the disciplines involved in cerebrovascular surgery. Of particular value in the text is the segment on epidemiology, particularly the chapter authored by Dr. Kace and associates. In this section and the section on clinical considerations, many of the pertinent aspects of atherosclerosis, as manifested by both cerebrovascular disease and lesions at other sites, are brought into perspective. In the section on pathology, popular theories relative to the etiology of transcient ischemic and previously asymptomatic carotid stenoses are advanced by Dr. Luzby.

The section on noninvasive studies has a detailed description of each noninvasive study currently available. The multiplicity of studies reviewed in this section underscore our current lack of standardization of diagnostic evaluations and the rapidly evolving technology in the noninvasive assessment of cerebrovascular disease. Although many methods are reviewed in great detail, the more recent introduction of transcranial Doppler is only briefly mentioned.

The surgical management of lesions of the cerebrovasculature is presented in somewhat repetitious detail, yet presents all available data addressing the respective clinical presentations. Dr. Moore handles the areas of controversy by having advocates of both operative and nonoperative management of lesions present their cases within the text.

This text should provide a complete reference to the current status of surgical management of cerebrovascular disease, with a significant amount of additional data regarding the disease process itself. The depth to which the text manages each of the respective issues is well beyond that of the usual book and is strongly recommended as a reference for the surgical management of this disease. For this reason, it should be a valuable addition to the literature and of significant value to neurologists, neurosurgeons, vascular surgeons, and cardiac surgeons.

RICHARD H. DEAN, M.D.
Winston Salem, North Carolina

Surgical Treatment of Metastatic Cancer. Steven A. Rosenberg. 286 pp. Philadelphia: J.B. Lippincott Co. 1987. $59.50.

THIS TOME is a contribution by active or former staff members of the National Cancer Institute (NCI) for the diagnosis and surgical treatment of metastatic disease to various organ sites. Chapters are organized and devoted to the biologic principles of the metastatic process, and to the diagnosis and surgical resection, with curative intent, of established metastases to the lung, liver, brain, and lymphatics. The editor addresses these organ sites to increase awareness of the value of surgery for the curative treatment of patients with metastases from solid tumors.

This monograph is organized into seven basic chapters that deal with the biology of cancer invasion, diagnosis, and surgical therapy. The introduction is organized to provide the reader with an overview of cancer biology, mechanisms of neoplastic invasion, and metastases. The author deals with the development of the cellular theories and the active process of invasion, and with biochemical mechanisms responsible for tumor cell interaction, membrane alterations with the invasive process, and tumor cell surface receptors. In a succinct fashion, this chapter organizes past and contemporary hypotheses drawn from the vast laboratory and clinical experience available for cancer invasion and metastases. The more recent concepts of angiogenesis and metastases are likewise reviewed with conclusions of experimental immunotherapy of metastases.

The remaining six chapters deal predominantly with the clinical aspects of diagnosis and therapy of metastases of the aforementioned organ sites. Chapters 2 and 3 deal with the diagnosis and surgical therapy of pulmonary metastases. Each chapter is well-organized and comprehensive and is supported with radiographs, figures, and tables, which are complementary to the text. The chapter for resection of pulmonary metastases reviews the extensive experience of the Surgical Branch of the NCI for the management of metastatic soft-tissue sarcomas and osteogenic sarcomas as a component of disease of favorable histologic types. The clinical relevance of this organization distinguishes the less favorable prognosis for head and neck cancer, colorectal carcinoma, uterine-cervical cancer, breast carcinoma, and melanoma.

Chapters devoted to the diagnosis and therapy of hepatic metastases are well-organized, contemporary, and are authored by surgeons experienced in the management of metastatic disease to this organ. The authors place in perspective the organization and interpretation of diagnostic parameters (*e.g.,* liver function tests, radiography, imaging, ultrasonography, computed tomography [CT] and magnetic resonance imaging [MRI]). The section that deals with diagnostic arteriography and venography is abbreviated and is a shortcoming of this chapter. Conversely, the review of hepatic resections is comprehensive, and gives the reader a candid appraisal of clinically applicable approaches for the workup and management of solid tumor metastases to the liver. An extension of this chapter provides insight into endocrine metastases and metastases of noncolorectal, nonendocrine origin, and the end results with hepatic resections for these sites. The chapter concludes with the technical approaches, indications, and results for the various hepatic resections. Both chapters are supported with contemporary, pertinent bibliography.

The chapter that reviews brain metastases is likewise organized to provide the clinician an overview of the incidence, biology, clinical features, neurodiagnostic evaluation, and principles for management of this metastatic site. Also addressed are medical management principles, determinants of radiation therapy responses, and adjunctive therapies available other than surgery. Although this volume is not a text of descriptive techniques, details for contemporary management and operative techniques are enumerated to provide insight for the impact of technical advances in the management of brain metastasis. Survival is addressed with evaluation of the prognostic factors relevant to individual cases (*i.e.*, primary histologic type and performance status). An encyclopedic bibliography is provided for this comprehensive, readable chapter.

The final chapter is dedicated to the treatment of regional lymph node metastases of various histologic types. The diagnostic parameters discussed include lymphangiography, lymphoscintigraphy, and MRI. The author addresses randomized studies that evaluate the efficacy of prophylactic node dissections for extremity melanoma, carcinoma of the oral cavity, and breast carcinoma. These therapeutic dilemmas are succinctly reviewed with the conclusion that no benefit exists for prophylactic nodal dissection, and there appears to be no role for debulking of disease in which effective chemotherapy is available. The merit of this chapter is the comprehensive review of retrospective studies for node dissections of specific tumors in various (19 total) organ sites. While these studies are predominantly retrospective, a review of this therapeutic option has been drawn together in a concise and clear presentation for the efficacy of lymphadenectomy as determined by disease-control rates and actuarial survival.

In summary, this reference textbook is a well-organized, readable, comprehensive tome of clinical value to the surgical oncologist who deals with neoplasms of these various organ sites. Further, it will have broad appeal to the surgical resident and practicing surgeon allowing organization of diagnostic, management, and therapeutic concepts for tumors metastatic to these organs.

KIRBY I. BLAND, M.D.
Gainesville, Florida

Surgical Diseases of the Pancreas. John M. Howard, George L. Jordan, Jr., and Howard A. Reber. 958 pp. Philadelphia: Lea & Febiger. 1987. $145.00.

THE FIRST EDITION of this book by Drs. Howard and Jordan was published in 1960. Since that time, major advances have occurred in the investigation and treatment of pancreatic disorders. Drs. Howard and Jordan are well-known distinguished senior surgeons who have contributed a great deal to pancreatic surgery. Dr. Reber, co-editor, eminently fills the role of the younger surgeon-investigator to add balance to this work, which has evolved into a perfect blend of the scientific, the clinical, and the surgical-technical aspects of pancreatic diseases.

The book clearly represents the end result of a very arduous task. It is well written and the illustrations are good. Historical overviews, basic anatomy and physiology, clinical concepts and controversies, and surgical principles and preferences are all covered in detail and embrace virtually all facets of pancreatic surgery. I would have preferred to have a better balance of the internist's and the invasive radiologist's views, but this does not detract too much from the value of the book since it is written mainly by surgeons and primarily for surgeons. The wide spectrum of pancreatitis as seen in various parts of the world is well delineated by an array of international experts. I predict that this book is going to be a success. Despite some minor deficiencies, I believe that it is destined to become a standard reference for surgeons operating on the pancreas.

A. RAHIM MOOSSA, M.D.

Letters to the Editor

January 28, 1987

Dear Editor:

I refer to "An Analysis of Survival and Treatment Failure Following Abdominoperineal and Sphincter-saving Resection in Dukes' B and C Rectal Carcinoma."[1] By comparing the effectiveness of abdominoperineal resection and sphincter-saving operations, the authors strongly imply that these operations are interchangeable in the treatment of rectal cancer. Nothing could be further from the truth. Abdominoperineal resections should be reserved for those patients in whom sphincter-salvage is not possible. If sphincter-salvage is attainable, why would one add the perineal portion of the operation to the treatment plan? It appears to me that the logical plan for the treatment of rectal cancer would be clarified from the following algorithm: (1) abdominal exploration to determine the presence or absence of both advanced gross distant metastasis and/or local invasion; (2) a resection of the primary tumor including the proximal lymphatic routes and an appropriate (whatever that is) length of distal cuff below the lesion; (3) abdominoperineal resection if no appropriate distal cuff is attainable; (4) the question of feasibility of an anastomosis (stapled, sewn, pull-through, or colo-anal) if a satisfactory cuff is attainable; (5) anastomosis, if attainable, should be done; and (6) no need to complete the perineal resection if anastomosis is not possible. The cancer operation has been done and a Hartmann procedure with an end sigmoid colostomy is the appropriate operation.

Nowhere in the algorithm is there a choice for performing an abdominoperineal resection for a lesion appropriately conducive to sphincter salvage or vice-versa. The one instance in which anastomosis may be considered for a lesion more amenable to abdominoperineal resection would be when palliation is best served with an anastomosis. Consider, for instance, the patient with liver metastasis in which even a 0.5-cm. cuff may be considered adequate in order to keep the gastrointestinal tract in continuity.

It is true that the choice of operation may also be determined by the technical expertise of the surgeon, by the experience with alternative anastomotic procedures, by the habitus of the patient, and the presence of advanced metastatic disease. Nevertheless, these factors do not in any way allow a general comparison of the efficacy of these procedures for the treatment of rectal cancer.

B. A. PORTIN, M.D.
Buffalo, New York

Reference

Dear Editor:

Dr. Portin presents an "algorithm" for the treatment of rectal cancer in which he asserts that a sphincter-saving procedure should be performed whenever technically feasible. If the therapeutic formula presented by Dr. Portin had been supported by reliable data, we would agree that our own analysis would not have been necessary. It is precisely because there is considerable controversy relative to the propriety of sphincter-saving operations that our study was performed. Dr. Portin himself underscores this controversy when he suggests that an anterior resection should be performed with "an appropriate (whatever that is) length of distal cuff below the lesion." He further goes on to state that if no appropriate distal cuff is attainable, abdominoperineal resection is necessary and should be performed. In our view, these statements provide justification for our study in that one of its specific aims was to determine the significance of distal margins of resection in sphincter-saving procedures. Our data clearly indicated that treatment failure and survival were not significantly different in patients undergoing sphincter-saving resections whose distal resection margins were <2 cm, 2–2.9 cm, or >3 cm. Further, the number of positive nodes, Dukes' class, and tumor size were not important discriminants in the selection of one operation over the other. This information tends to support Dr. Portin's contention that abdominoperineal resections should be reserved for those patients in whom sphincter-salvage is not possible; however, it is perplexing that he would be comfortable in accepting this approach without the benefit of a well-defined analysis. Perhaps it is Dr. Portin's view that our study was carried out to confirm that which he considered to be self-evident. The fact that we saw fit to perform our study indicates that we disagree with this contention.

NORMAN WOLMARK, M.D.
BERNARD FISHER, M.D.
Pittsburgh, Pennsylvania

August 25, 1987

Dear Editor:

We read with interest the paper of Taylor et al. entitled *Digital Ischemia as a Manifestation of Malignancy.*[1] However, in our view, the omission of several references greatly detracts from this paper's value. In the first place, no mention was made of the series of six cases of digital gangrene associated with neoplasm, which we reported in 1978 in *La Nouvelle Presse Medicale,*[2] a series that is still the largest so far published in this field. *La Nouvelle Presse Medicale* is the most respected French medical journal devoted to internal medicine, and when Eugene Garfield considered which medical journals had the greatest impact,[3] he classified *La Nouvelle Presse Medicale* as 15th in world medical literature and second among the non-English language journals.

Taylor et al.[1] also forgot to include a reference to the work of Kaniak[4] or to a report published in 1985 by Petri et al.[5] Even more surprising was their failure to mention that case n°4 in their series had previously been published.[6]

As a member of the Committee of Directors of the Journal des Maladies Vasculaires, I know how difficult it is to check carefully those parts of papers proposed for publication that concern references. However, this tedious and time-consuming work is important for several reasons: (1) when an important series on the same subject considered is missing, the value of a paper proposed for publication is spuriously increased; (2) some authors try, and sometimes succeed, in publishing their case reports in several journals, which makes it difficult to establish the exact number of cases reported; and (3) the prestige of a journal depends on how often it is referred to in other journals, so that a missing reference is detrimental not only to the authors but to the journal.

Professor Michel Vayssairat

October 19, 1987

Dear Editor:

We have read with interest the letter from Dr. Vayssairat regarding our paper on the association between digital gangrene and malignancy. Dr. Vayssairat has expressed several concerns that may be ennumerated as follows: (1) We have omitted from our review reference to several previously published papers on this same subject.[1-3] (2) It is Dr. Vayssairat's opinion that our omission of these references detracts from the value of our paper. (3) Our failure to cite the references has detracted from the prestige of the journals in which papers were published.

We acknowledge the omission of the previously published papers from our review of the literature. All authors recognize the difficulty involved in conducting a comprehensive review of the world's literature on any subject due to the profusion of scientific articles and journals currently extant. We specifically recognized and cited this difficulty in our paper. Quoting from the abstract, "to date however we are aware of 23 published case reports of digital gangrene associated with malignancy" and from the body of the paper in which we stated, "to our knowledge there have been 23 published case reports linking digital ischemia and malignant disease" indicates with this specific wording our recognition of the difficulty of compiling a comprehensive literature review. We are pleased to acknowledge the contributions of the other authors and specifically acknowledge that Dr. Vayssairat's case series contained a description of six patients whereas ours described only five, making his series published in Nouvelle Presse Medicale the largest series reported (of which we are aware) in the medical literature.

With regard to Dr. Vayssairat's second contention that our failure to mention these references greatly detracts from our paper's value, we offer the following comment. The purpose of our paper was to inform the reader regarding our experience with, and our opinions about, the association of digital gangrene and malignancy, and was specifically not to establish our primacy or indeed supremacy in this field. We believe the paper's value rests exclusively in its ability to convey information to the reader. Our citation of 41 references in the bibliography provides ample evidence of our desire to recognize the contributions of others to this field.

With regard to Dr. Vayssairat's contention that our failure to cite the listed references detracts from the prestige of the medical journals in which they were published, we comment that the value and prestige of a medical journal is a matter to be decided by the subscribers and the readers thereof. We have never ascribed great significance to the so-called citation index.

Parenthetically, many of us who contribute regularly to the medical literature have frequently encountered reports on subjects regarding which we have also published papers we personally consider of seminal importance, only to find our publications absent from the bibliography of the new work. We do not consider such omissions to reflect anything more than the substantial difficulty involved in compiling a complete list of publications on any subject, especially if one wishes to include articles published in the many languages used by various minorities of the world's scientific community.

November 18, 1987

Dear Editor:

Silberman reported his experience with clinical stage I melanoma among patients who presented with lesions of Clark levels deep III through V.[1] Only 10% of his patients had positive lymph node dissections. He borrowed a potential 5-year survival advantage of 25% for patients with occult disease from a retrospective study by Roses et al.[2] He concluded that the therapeutic benefit of routine ELND for such patients was not justified.

Two randomized, prospective trials have concluded that there is no advantage to ELND among patients with clinical Stage I disease.[3,4] Nevertheless, numerous retrospective studies have found a significant survival benefit for this procedure. Analysis of the study techniques reveals an explanation for the conflicting conclusions.

In prospective clinical trials patients may be seen every 1–2 months and told to return promptly if a node becomes palpable. Veronesi et al. reported a 50% 5-year survival among N_{1b} patients, who developed nodal disease during attentive follow-up.[3] Survival was equally good for N_{o+} patients who had occult metastases at elective dissection. These patients suffered only the staging consequences of their pathological Stage II disease.

Patients whose nodal disease is allowed to progress suffer the more serious tumor burden consequence of their clinical Stage II disease. Most retrospective studies focus attention on the many variables associated with the primary lesion. Changes in lymph nodes are seldom reported in a quantitative fashion. Investigators who report benefit from ELND should report the number and size of positive nodes recovered at delayed dissection. The excess deaths that occur among these patients are most likely the result of distant metastases seeded from relatively advanced regional disease. This thesis should be simple to verify. Silberman should be commended for carefully including this data in his paper. His advice to defer regional node dissection is sound. The calculated, potential benefit is small, and careful follow-up of intact regional nodes produces equally good results.

Melanoma appears to follow biologic principles previously suggested for breast cancer.[5] The thoughts expressed here are best understood in light of that hypothesis.

RICHARD A. EVANS, M.D.
Houston, Texas

5. Evans RA. Host resistance to carcinoma of the breast. South Med J 1980; 73:1261–1263.

Dear Editor:

I would like to thank Dr. Evans for his kind comments. His hypothesis regarding the reason the retrospective studies have consistently demonstrated a survival advantage while the prospective studies have not may well be correct.

I would like to point out, however, that although it does not appear that prophylactic regional lymph node dissection (PRLND) offers a significant therapeutic benefit, I often perform the procedure for prognostic and staging information. The problem with which one is faced is that the patient whose microstaging is sufficiently worrisome to make him/her a candidate for PRLND is also the patient who should be considered for placement on an adjuvant trial. Most Stage I and II adjuvant trials require the lymph node dissection as an entrance requirement. Thus, the node dissection in melanoma becomes analagous to the axillary dissection for breast cancer, namely, the result of the dissection leads to a decision regarding systemic therapy. The point that must be made is that the patient must be made aware of the distinction between a therapeutic operation and a staging operation.

A. W. SILBERMAN, M.D.
Los Angeles, California

August 14, 1987

Dear Editor:

The paper entitled *Drug-induced esophageal strictures* by Bonavina et al. was most interesting.[1]

It is probable that esophageal ulceration and sometimes stricture is more common after drug ingestion than we know. After all, it is likely that reported cases are merely the tip of a very large iceberg. For the same reasons, the drug list in Table 2 is probably incomplete. A couple of years ago I was able to report a case of severe ulceration of the esophagus due to slow-release theophylline,[2] a commonly used drug. At that time only one other case had been reported.[3] In neither of these two cases did stricture result, but one could postulate that many strictures are treated in their late stages long after the initial insult has been forgotten. It is therefore worth repeating once again Evans' advice that tablets should be taken either before or during meals and washed down liberally with adequate fluid.

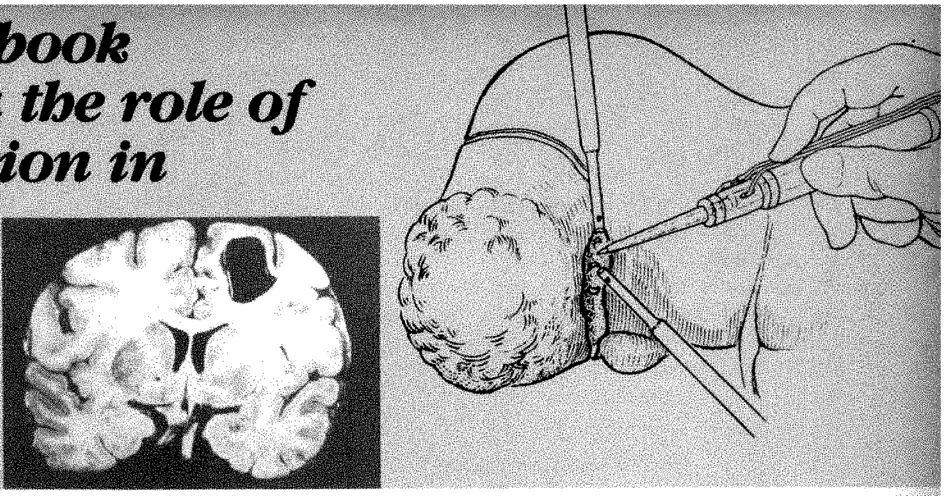
October 8, 1987

Dear Editor:

I appreciate Dr. Stoller's addition of the drug theophylline to the list of drugs known to have caused esophageal injury. I apologize that our search did not uncover his publication. I wish to underscore his statement that "it is likely that the reported cases are merely the tip of a very large iceberg." No doubt there are many other drugs that could be added to the list. I concur with his quoting of Evans' advice that tablets should be taken either before or during meals and washed down liberally with adequate fluid. His advice certainly is sound. I wish he would have told us who Evans was.

TOM R. DEMEESTER, M.D.
Omaha, Nebraska

Now...the new book that shows you the role of surgical resection in the curative treatment of metastatic cancer

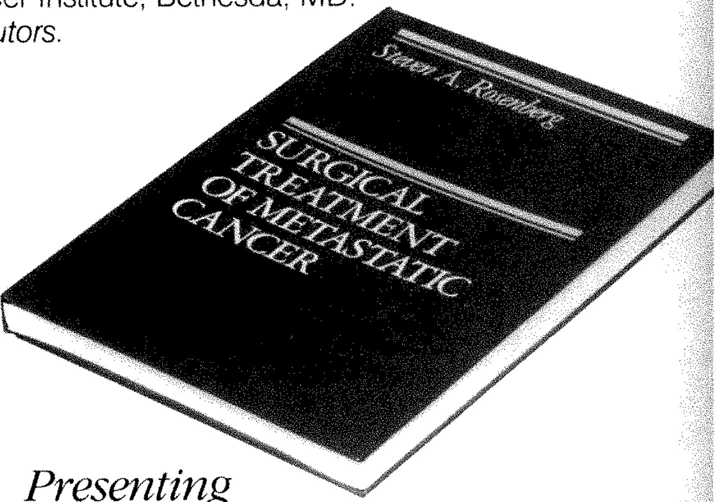


SURGICAL TREATMENT of METASTATIC CANCER

Edited by Steven A. Rosenberg, M.D., Ph.D.

Chief of Surgery, National Cancer Institute, Bethesda, MD.

9 contributors.



> *“For many patients with isolated visceral metastases from solid tumors, surgical resection of those metastatic deposits represents the best opportunity for cure. For patients with solitary pulmonary and hepatic metastases, up to 30% of patients may experience prolonged disease-free survival after metastasectomy. Only a small subset of patients with metastatic cancer are likely to benefit from surgical resection and identification of these patients is an important part of the application of this treatment.”*
>
> **—from the *Preface***

Taking a bold approach to treatment

Now, for the first time, here is an in-depth resource that describes the role of surgical resection in the treatment of metastatic cancer. Editor Dr. Steven A. Rosenberg, Chief of Surgery at the National Cancer Institute, and a leading figure in cancer research and treatment, poses the premise that the role of surgical resection in treating metastatic cancer has indeed been underappreciated. He and a distinguished group of contributors have designed this book to present the essential information oncologists and surgeons need to understand the value of this treatment.

Presenting a highly significant option

Detailed information is presented concerning:

- the modern understanding of the biology of the metastatic process
- up-to-date techniques for the diagnosis of lung, liver, and brain metastases
- indications for and results of the surgical resection of lung, liver, and brain metastases
- the indications for lymph node dissection in the treatment of cancer.

Notice to Contributors and Subscribers

ANNALS OF SURGERY is a monthly journal which considers for publication original articles in the field of surgery. It is the oldest continuously published journal in the English language solely devoted to the surgical sciences. The Editorial Board considers only papers judged to offer significant contributions to the advancement of surgical knowledge.

CONTRIBUTIONS. Four typed copies of the manuscript and four copies of the illustrations should be sent prepaid to the Chairman of the Editorial Board of Annals of Surgery.

David C. Sabiston, Jr., M.D.
Annals of Surgery
Department of Surgery
Duke University Medical Center
Durham, North Carolina 27710

Annals of Surgery has joined a number of other leading Medical Journals which endorse the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals." These Requirements were established by an agreement among a number of Editors of Clinical Journals in the United States, Canada and the United Kingdom. The Criteria for preparation of manuscripts are as follows:

SUMMARY OF REQUIREMENTS

Type manuscript double spaced, including title page, abstract, text, acknowledgments, references, tables, and legends.

Each manuscript component should begin on a new page, in this sequence:

- Title page
- Abstract and key words
- Text
- Acknowledgments
- References
- Tables: each table, complete with title and footnotes, on a separate page
- Legends for illustrations

Illustrations must be good quality, unmounted glossy prints usually 12.7 by 17.3 cm (5 by 7 in.) but no larger than 20.3 by 25.4 cm (8 by 10 in.).

Submit the required number of copies of manuscript and figures (*see* journal's instructions) in heavy-paper envelope. Submitted manuscript should be accompanied by covering letter, as described under "Submission of Manuscripts," and permissions to reproduce previously published materials or to use illustrations that may identify subjects.

Follow journal's instructions for transfer of copyright.

Authors should keep copies of everything submitted.

PREPARATION OF MANUSCRIPT

Type manuscript on white bond paper, 20.3 by 26.7 cm or 21.6 by 27.9 cm (8 by 10½ in. or 8½ by 11 in.) or ISO A4 (212 by 297 mm) with margins of at least 2.5 cm (1 in.). Use double spacing throughout, including title page, abstract, text, acknowledgments, references, tables, and legends for illustrations. Begin each of the following sections on separate pages: title page, abstract and key words, text, acknowledgments, references, individual tables, and legends. Number pages consecutively, beginning with the title page. Type the page number in the upper right-hand corner of each page.

Manuscripts will be reviewed for possible publication with the understanding that they are being submitted to one journal at a time and have not been published, simultaneously submitted, or already accepted for publication elsewhere. This does not preclude consideration of a manuscript that has been rejected by another journal or of a complete report that follows publication of preliminary findings elsewhere, usually in the form of an abstract. Copies of any possibly duplicative published material should be submitted with the manuscript that is being sent for consideration.

TITLE PAGE

The title page should contain [1] the title of the article, which should be concise but informative; [2] a short running head or footline of no more than 40 characters (count letters and spaces) placed at the foot of the title page and identified; [3] first name, middle initial, and last name of each author, with highest academic degree(s); [4] name of department(s) and institution(s) to which the work should be attributed; [5] disclaimers, if any; [6] name and address of author responsible for correspondence about the manuscript; [7] name and address of author to whom requests for reprints should be addressed, or statement that reprints will not be available from the author; [8] the source(s) of support in the form of grants, equipment, drugs, or all of these.

ABSTRACT AND KEY WORDS

The second page should carry an abstract of not more than 150 words. The abstract should state the purposes of the study or investigation, basic procedures (study subjects or experimental animals and observational and analytic methods), main findings (give specific data and their statistical significance, if possible), and the principal conclusions. Emphasize new and important aspects of the study or observations. Use only approved abbreviations (*see* list of Commonly Used Approved Abbreviations elsewhere in this document).

Key (indexing) terms: Below the abstract, provide and identify as such, three to 10 key words or short phrases that will assist indexers in cross-indexing your article and that may be published with the abstract. Use terms from the Medical Subject Headings list from *Index Medicus* whenever possible.

TEXT

The text of observational and experimental articles is usually—but not necessarily—divided into sections with the headings Introduction, Methods, Results, and Discussion. Long articles may need subheadings within some sections to clarify their content, especially the Results and Discussion sections. Other types of articles such as case reports, reviews, and editorials are likely to need other formats, and authors should consult individual journals for further guidance.

Introduction: Clearly state the *purpose* of the article. Summarize the rationale for the study or observation. Give only strictly pertinent references, and do not review the subject extensively.

state of the art of

TRAUMA SURGERY

NEW!

Edited by **Joseph A. Moylan, M.D.**
With 30 Distinguished Contributors

Brings you the state of the art of trauma surgery

This comprehensive reference focuses on modern-day surgical management of single- and multi-system trauma in the environment of sophisticated high technology used in diagnosis and treatment. It brings you the state of the art of trauma surgery as well as practical approaches used in daily practice by surgeons recognized for their trauma expertise.

Provides you with practical approaches to the complete care of the trauma patient

TRAUMA SURGERY addresses the *complete care* of the trauma patient. Integrating basic pathophysiology with practical technical information on assessment, evaluation, diagnosis, current surgical techniques, and the anticipation and prevention of complications—information addressing the *total management* of the trauma patient. Each chapter presents practical information on mechanism of injury, diagnostics, and therapeutic approaches, emphasizing practical, step-by-step methods which the contributing authors find helpful in solving and treating the trauma patient. Special sections cover shock, monitoring, management of a trauma unit, and immediate care of the trauma patient.

covers both common and complex injuries

Organized by area and type of trauma, the book covers practical approaches to the management of both common and complex injuries including: central nervous system trauma, facial trauma, neck injuries, thoracic trauma, burns, abdominal and pelvic trauma, vascular and nerve injuries, GYN trauma, and pediatric trauma surgery.

Emphasizes decision making

This remarkable book emphasizes decision making in trauma surgery. Alternative procedures and courses of action are outlined, however, specific recommendations are made.

Brief Summary: Please see package insert for full prescribing information.
INDICATIONS AND USAGE: Topical corticosteroids are indicated for the relief of the inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses.
CONTRAINDICATIONS: Topical corticosteroids are contraindicated in those patients with a history of hypersensitivity to any of the components of the preparation.
PRECAUTIONS: ***General:*** Systemic absorption of topical corticosteroids has produced reversible hypothalamic-pituitary-adrenal (HPA) axis suppression, manifestations of Cushing's syndrome, hyperglycemia and glucosuria in some patients. Conditions which augment systemic absorption include the applications of the more potent steroids, use over large surface areas, prolonged use and the addition of occlusive dressings. Therefore, patients receiving a large dose of a potent topical steroid applied to a large surface area and under an occlusive dressing should be evaluated periodically for evidence of HPA axis suppression by using the urinary free cortisol and ACTH stimulation tests. If HPA axis suppression is noted, an attempt should be made to withdraw the drug, to reduce the frequency of application, or to substitute a less potent steroid. Recovery of HPA axis function is generally prompt and complete upon discontinuation of the drug. Infrequently, signs and symptoms of steroid withdrawal may occur, requiring supplemental systemic corticosteroids. Children may absorb proportionally larger amounts of topical corticosteroids and thus be more susceptible to systemic toxicity. (See PRECAUTIONS—Pediatric Use.) If irritation develops, topical corticosteroids should be discontinued and appropriate therapy instituted. In the presence of dermatological infections, the use of an appropriate antifungal or antibacterial agent should be instituted. If a favorable response does not occur promptly, the corticosteroid should be discontinued until the infection has been adequately controlled.
Information for the Patient: Patients using topical corticosteroids should receive the following information and instructions: 1. This medication is to be used as directed by the physician. It is for external use only. Avoid contact with the eyes. 2. Patients should be advised not to use this medication for any disorder other than for which it has been prescribed. 3. The treated skin area should not be bandaged or otherwise covered or wrapped as to be occlusive unless directed by the physician. 4. Patients should report any signs of local adverse reactions especially under occlusive dressing. 5. Parents of pediatric patients should be advised not to use tight-fitting diapers or plastic pants on a child being treated in the diaper area, as these garments may constitute occlusive dressings.
Laboratory Test: The following test may be helpful in evaluating the HPA axis suppression: ACTH stimulation test
Carcinogenesis, Mutagenesis and Impairment of Fertility: Long-term animal studies have not been performed to evaluate the carcinogenic potential or the effect on fertility of topical corticosteroids. Studies to determine mutagenicity with prednisolone and hydrocortisone have revealed negative results.
Pregnancy Category C: Corticosteroids are generally teratogenic in laboratory animals when administered systemically at relatively low dosage levels. The more potent corticosteroids have been shown to be teratogenic after dermal application in laboratory animals. There are no adequate and well-controlled studies in pregnant women of teratogenic effects from topically applied corticosteroids. Therefore, topical corticosteroids should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus. Drugs of this class should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.
Nursing Mothers: It is not known whether topical administration of corticosteroids could result in sufficient systemic absorption to produce detectable quantities in breast milk. Systemically administered corticosteroids are secreted into breast milk in quantities NOT likely to have a deleterious effect on the infant. Nevertheless, caution should be exercised when any topical corticosteroids are administered to a nursing woman.
Pediatric Use: Pediatric patients may demonstrate greater susceptibility to topical corticosteroid-induced HPA axis suppression and Cushing's syndrome than mature patients because of a larger skin surface area to body weight ratio. Hypothalamic-pituitary-adrenal (HPA) axis suppression, Cushing's syndrome and intracranial hypertension have been reported in children receiving topical corticosteroids. Manifestations of adrenal suppression in children include linear growth retardation, delayed weight gain, low plasma cortisol levels, and absence of response to ACTH stimulation. Manifestations of intracranial hypertension include bulging fontanelles, headaches and bilateral papilledema. Administration of topical corticosteroids to children should be limited to the least amount compatible with an effective therapeutic regimen. Chronic corticosteroid therapy may interfere with the growth and development of children.
ADVERSE REACTIONS: The following local adverse reactions are reported infrequently with topical corticosteroids, but may occur more frequently with the use of occlusive dressings. These reactions are listed in an approximately decreasing order of occurrence: burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, hypopigmentation, perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, miliaria.
OVERDOSAGE: Topically applied corticosteroids can be absorbed in sufficient amounts to produce systemic effects. (See PRECAUTIONS.)
DOSAGE AND ADMINISTRATION: Topical corticosteroids are generally applied to the affected area as a thin film three or four times daily depending on the severity of the condition. Occlusive dressings may be used for the management of psoriasis or recalcitrant conditions. If an infection develops, the use of occlusive dressings should be discontinued and appropriate antimicrobial therapy instituted.
HOW SUPPLIED: 1 oz. tube with rectal applicator.
CAUTION: Federal law prohibits dispensing without prescription.

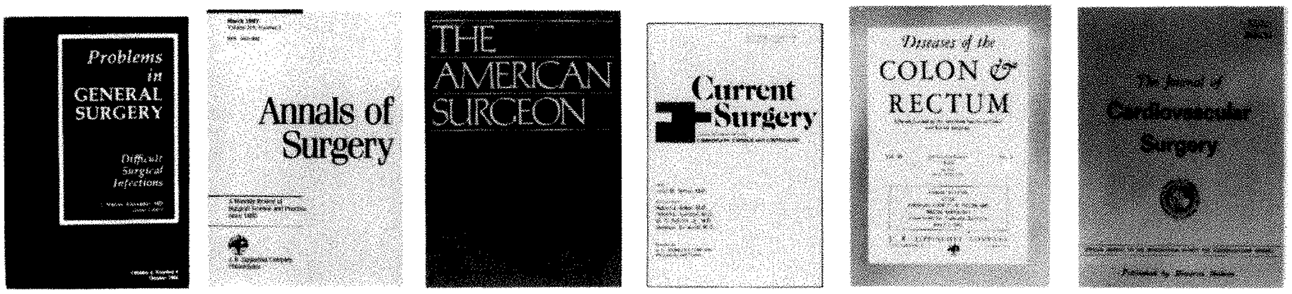
Journals and Series of Interest to SURGEONS

Indispensable tools for maintaining professional competency



Problems in General Surgery

Lloyd M. Nyhus, M.D., Editor.

This series of hardbound volumes features a symposium on a specific topic in general surgery in each issue. It serves as an outlet for the publication of original articles aimed at defining and suggesting solutions to difficult problems encountered in practice. Clinical problems are emphasized, with concentration on difficulties and complications. Leading authorities, chosen for their expert knowledge in their assigned topics, contribute articles on specific subjects, pooling the expertise of specialists for the benefit of generalists.

Published quarterly. Individual rate $59.00 per year (U.S.), $68.00 (elsewhere). Residents $39.00 (U.S. only).

Annals of Surgery

Official Publication of The American Surgical Association, The Southern Surgical Association, Philadelphia Academy of Surgery, and the New York Surgical Society

David C. Sabiston, Jr., M.D., Chairman of Editorial and Advisory Board.

Annals of Surgery—the world's oldest exclusively surgical journal—has provided the medical community with reports on significant contributions to the advancement of surgical science and practice for over 100 years. Its 20,000 subscribers find it a practical way to keep up to date with important developments in surgery.

Published monthly. Individual rate $53.00 per year (U.S.), $70.00 (elsewhere). Residents $35.00 (U.S.), $52.00 (Canada).

The American Surgeon

Official Publication of the Southeastern Surgical Congress, the Midwest Surgical Association, the Association of Clinical Anatomists, and the Society of American Gastrointestinal Endoscopic Surgeons (SAGES)

Arlie R. Mansberger, Jr., M.D., Editor-in-Chief.

An authoritative forum for the publication of original papers contributing to the advancement of surgery. Each issue contains information on the clinical application of new methods used in the management of patients; review articles with continuing education questions; condensed reviews of unusual case reports; "How I Do It" articles emphasizing the technical aspects of surgery.

Published monthly. Individual rate $49.00 per year (U.S.), $60.00 (elsewhere). Residents $32.00 (U.S. only).

Current Surgery

The Official Journal of the Association of Program Directors in Surgery

Lloyd M. Nyhus, M.D., Editor.

An internationally renowned editorial board prepares abstracts from every dependable source of surgical information throughout the world. Drawing on their own clinical experience and that of other recognized authorities, the members of the board provide commentary to further amplify and illuminate the material contained in each abstract. Also included are editorials, reports of new discoveries, residents' corner, and book reviews.

Published bimonthly. Individual rate $40.00 per year (U.S.), $46.00 (elsewhere). Residents $26.00 (U.S.), $32.00 (Canada).

Diseases of the Colon and Rectum

Official Journal of the American Society of Colon and Rectal Surgeons and the International Society of University Colon and Rectal Surgeons

Robert W. Beart, Jr., M.D., Editor-in-Chief.

This journal publishes reports on contemporary practice in the diagnosis and management of proctologic diseases and surgery. International in scope, it includes articles from physicians worldwide who share their important discoveries that offer new insights into basic research in metabolism, pathology, virology, radiology, and the clinical practice of medicine and surgery.

Published monthly. Individual rate $74.00 per year (U.S.), $89.00 (elsewhere). Residents $44.00 (U.S.), $59.00 (Canada).

Journal of Cardiovascular Surgery

Official Journal of the International Society for Cardiovascular Surgery

J. E. Connolly and S. S. Rose, Co-chief Editors.

The Journal is devoted to disease of the heart and the entire vascular system. It presents concise, informative coverage of the most significant work being done in diagnostic, experimental, and clinical surgery of the heart and blood vessels.

Published bimonthly. Individual rate $80.00 per year (North America only).

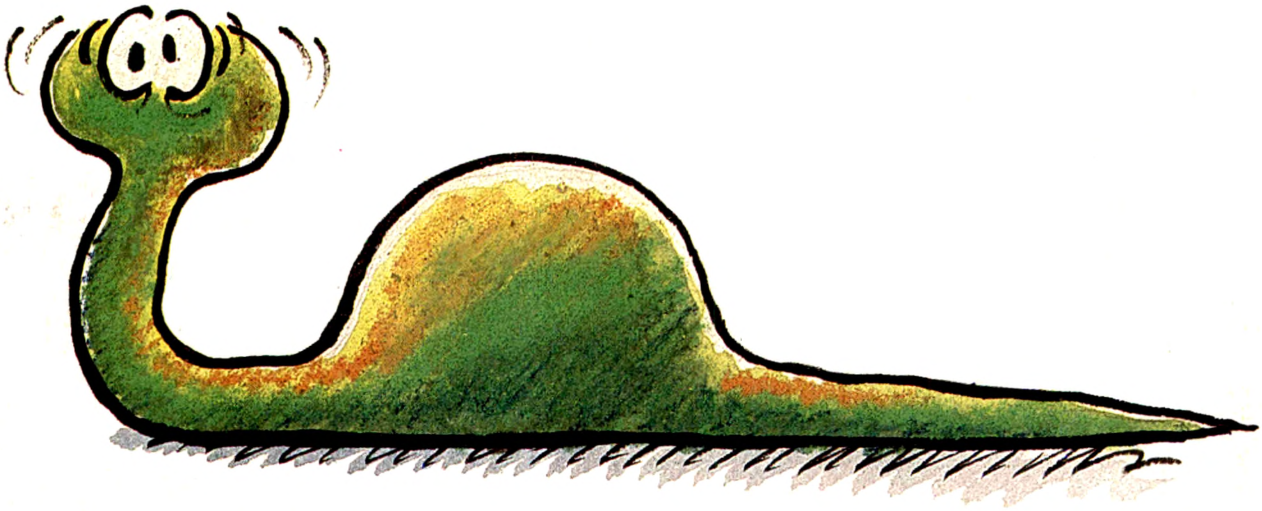
If the movement needs improvement...
Colace® or Peri-Colace®



Recommend the time-tested anticonstipants that relieve gently and reliably. Colace (docusate sodium) softens the stool and helps prevent straining . . . especially important for patients with anorectal disorders.

When laxative action is also needed, Peri-Colace (casanthranol and docusate sodium) both softens stools and stimulates peristalsis to correct constipation, usually overnight.

Colace offers you the flexibility of 50mg or 100mg capsules, syrup or liquid. Peri-Colace is available in both capsules and syrup. Recommend them with confidence for virtually all your adult and pediatric patients.

Gentle relief you've relied on for over 25 years

In intra-abdominal and gynecologic infection due to indicated organisms

CEFOTAN® IM/IV

(cefotetan disodium)

Does so much for so much less than cefoxitin

For Intravenous or Intramuscular Use
BRIEF SUMMARY

INDICATIONS AND USAGE

TREATMENT: CEFOTAN® (cefotetan disodium) is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary tract infections caused by *E coli, Klebsiella* species (including *K pneumoniae*), *Proteus mirabilis* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri*, and *Morganella morganii*).

Lower respiratory tract infections caused by *Streptococcus pneumoniae* (formerly *D pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K pneumoniae*), and *E coli.*

Skin and skin structure infections caused by *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis,* Streptococcus pyogenes* and *Streptococcus* species (excluding enterococci), and *E coli.*

Gynecologic infections caused by *Staphylococcus aureus*† (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis,* Streptococcus* species (excluding enterococci), *E coli, Proteus mirabilis, Neisseria gonorrhoeae, Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*), *Fusobacterium* species,† and gram-positive anaerobic cocci (including *Peptococcus* and *Peptostreptococcus* species†).

Intra-abdominal infections caused by *E coli, Klebsiella* species (including *K pneumoniae*†), *Streptococcus* species (excluding enterococci), and *Bacteroides* species (excluding *B distasonis, B ovatus, B thetaiotaomicron*).

Bone and joint infections caused by *Staphylococcus aureus.*†

***NOTE:** Some strains of *Staphylococcus epidermidis* are resistant to cefotetan.

† Efficacy for this organism in this organ system was studied in fewer than ten infections.

PROPHYLAXIS: The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (eg, cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

Before therapy with CEFOTAN is instituted, careful inquiry should be made to determine whether the patient has had previous hypersensitivity reactions to cefotetan disodium, cephalosporins, penicillins, or other drugs. This product should be given cautiously to penicillin-sensitive patients. Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs. If an allergic reaction to CEFOTAN occurs, discontinue the drug. Serious acute hypersensitivity reactions may require epinephrine and other emergency measures.

Pseudomembranous colitis has been reported with the use of cephalosporins (and other broad-spectrum antibiotics); therefore, it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use.

Treatment with broad-spectrum antibiotics may alter normal flora of the colon and may permit overgrowth of clostridia. Studies indicate a toxin produced by *Clostridium difficile* is one primary cause of antibiotic-associated colitis. Cholestyramine and colestipol resins have been shown to bind the toxin in vitro.

Mild cases of colitis may respond to drug discontinuance alone. Moderate to severe cases should be managed with fluid, electrolyte, and protein supplementation as indicated. When the colitis is not relieved by drug discontinuance, or when it is severe, oral vancomycin is the treatment of choice for antibiotic-associated pseudomembranous colitis produced by *C difficile.* Other causes should also be considered.

PRECAUTIONS

GENERAL: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity. Those at risk include patients with renal or hepatic impairment, or poor nutritional state. Prothrombin times should be monitored in patients at risk and exogenous Vitamin K administered as indicated.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

INFORMATION FOR PATIENTS: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

DRUG INTERACTIONS: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycoside antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

DRUG/LABORATORY TEST INTERACTIONS: A false positive reaction for glucose in urine may occur with Benedict's or Fehling's solution.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels of Jaffe reaction and produce false increases in the levels of creatinine reported.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approx 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approx 2-4 times the usual human dose), only 1 of 10 treated animals was affected, and the degree of degeneration was mild. Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

CEFOTAN® (cefotetan disodium)

USAGE IN PREGNANCY: Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

USAGE IN NURSING MOTHERS: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies the following adverse effects were considered related to CEFOTAN therapy.

Gastrointestinal symptoms occurred in 1.5 percent of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700).

Hematologic laboratory abnormalities occurred in 1.4 percent of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300).

Hepatic enzyme elevations occurred in 1.2 percent of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2 percent of patients and included rash (1 in 150) and itching (1 in 700).

Local effects were reported in less than one percent of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

DOSAGE AND ADMINISTRATION

TREATMENT: The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6* grams	3 g every 12 hours IV

*Maximum daily dosage should not exceed 6 grams.

PROPHYLAXIS: To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION: When renal function is impaired, a reduced dosage schedule must be employed. The following dosage guidelines may be used.

DOSAGE GUIDELINES FOR PATIENTS WITH IMPAIRED RENAL FUNCTION

Creatinine Clearance mL/min	Dose	Frequency
>30	Usual Recommended Dose*	Every 12 hours
10-30	Usual Recommended Dose*	Every 24 hours
<10	Usual Recommended Dose*	Every 48 hours

*Dose determined by the type and severity of infection, and susceptibility of the causative organism.

Cefotetan is dialyzable and it is recommended that for patients undergoing intermittent hemodialysis, one-quarter of the usual recommended dose be given every 24 hours on days between dialysis and one-half the usual recommended dose on the day of dialysis.

HOW SUPPLIED

CEFOTAN is a dry, white to pale yellow powder supplied in vials containing cefotetan disodium equivalent to 1 g and 2 g cefotetan activity for intravenous and intramuscular administration. The 1 g dose is available in 10 mL and 100 mL vials, and the 2 g dose is available in 20 mL and 100 mL vials. The vials should not be stored at temperatures above 22°C and should be protected from light.

1 g in 10 mL vial (NDC 0038-0376-10); 2 g in 20 mL vial (NDC 0038-0377-20); 1 g in 100 mL vial (NDC 0038-0376-11); 2 g in 100 mL vial (NDC 0038-0377-21)

Totally current data and opinion on surgical management of colorectal cancers

Three volumes in the respected *Problems in General Surgery* series bring you up-to-the minute information that you can use *today* in your practice. Articles with real clinical relevance. Succinct presentations of major differences of opinion. Starkly different points of view on diagnosis and treatment—the questions you face when you make life-and-death decisions. The best thinking of leading practitioners to help you make the choices of modality of treatment most appropriate for each patient.

Here are information and insights that will challenge you to do something different and better in your practice the day after finishing each volume.

Abundant illustrations, diagrams, tables, charts. Totally current references, with commentary. *Each volume $30.00. Annual subscription (4 volumes) $59.00 (U.S.), $68.00 (elsewhere).* Send for the volumes you need today. And begin your subscription to this challenging series with the next volume.

Problems in GENERAL SURGERY

Lloyd M. Nyhus, *M.D., Editor*

Controversies in Cancer of the Breast and Colon

Vol. 2, No. 2

Thomas F. Nealon, Jr., *M.D., Guest Editor*

Partial contents include:

Limited Resection and Radical Radiation Therapy in the Treatment of Early Stage Breast Cancer / *Michael P. Osborne, MD, MS, FRCS, FACS*

Conservative Surgery / *Hugh Auchincloss, MD*

Delayed Reconstruction of the Breast after Mastectomy
Reuven K. Snyderman, MD

Abdominosacral Resection for Midrectal Cancer
Kenneth Eng, MD, and S. Arthur Localio, MD

Controversies in Adjuvant Therapy of Colorectal Cancer
Carlo E. Grossi, MD, and Thomas F. Nealon, Jr, MD

Cancer of the Rectum / Hernia

Vol. 3, No. 3

John L. Madden, *M.D., Guest Editor*

Partial contents include:

Abdominoperineal Resection of the Rectum
James M. Church, MD, and Victor W. Fazio, MD

External, Endocavitary, and Interstitial Irradiation in the Management of Carcinoma of the Rectum and Colon / *Ben Sischy, MD, FACR*

Sliding Inguinal Hernias: Errors in Surgical Management and Their Correction / *Joseph L. Ponka, MD*

Ambulatory Surgical Treatment of Groin Hernia: Prevention and Management of Complications / *George E. Wantz, MD, FACS*

Complications of Preperitoneal Hernia Repair
Raymond Pollak, MB, BCh, FRCS, and Lloyd N. Nyhus, MD

Controversies in Colon Cancer

Vol. 4, No. 1

Richard L. Nelson, *M.D., F.A.C.S., Guest Editor*

Partial contents include:

Screening for Carcinoma of the Colon: Pitfalls of the Hemoccult® Test / *Martin H. Poleski, MD, FRCP(C), FACP, and Philip H. Gordon, MD, FRCS(C), FACS*

The Adenoma-Carcinoma Sequence: An Update
Gary C. Vitale, MD, and John S. Spratt, MD

Classification Systems for Staging Colorectal Cancer: Past, Present, and Future / *L. Peter Fielding, MB, FRCS, FACS, and Garth H. Ballantyne, MD*

Radical Surgical Treatment of Colorectal Carcinoma
Richard L. Nelson, MD, FACS

Carcinoembryonic Antigen and Second-look Operation
John P. Minton, MD, PhD, FACS, and Armando Sardi, MD

Problems in General Surgery

Lloyd M. Nyhus, M.D., Editor.

This series of hardbound volumes features a symposium on a specific topic in general surgery in each issue. It serves as an outlet for the publication of original articles aimed at defining and suggesting solutions to difficult problems encountered in practice. Clinical problems are emphasized, with concentration on difficulties and complications. Leading authorities, chosen for their expert knowledge in their assigned topics, contribute articles on specific subjects, pooling the expertise of specialists for the benefit of generalists.

Published quarterly. Individual rate $59.00 per year (U.S.), $68.00 (elsewhere). Residents $39.00 (U.S. only).

Annals of Surgery

Official Publication of The American Surgical Association, The Southern Surgical Association, Philadelphia Academy of Surgery, and the New York Surgical Society

David C. Sabiston, Jr., M.D., Chairman of Editorial and Advisory Board.

Annals of Surgery—the world's oldest exclusively surgical journal—has provided the medical community with reports on significant contributions to the advancement of surgical science and practice for over 100 years. Its 20,000 subscribers find it a practical way to keep up to date with important developments in surgery.

Published monthly. Individual rate $53.00 per year (U.S.), $70.00 (elsewhere). Residents $35.00 (U.S.), $52.00 (Canada).

The American Surgeon

Official Publication of the Southeastern Surgical Congress, the Midwest Surgical Association, the Association of Clinical Anatomists, and the Society of American Gastrointestinal Endoscopic Surgeons (SAGES)

Arlie R. Mansberger, Jr., M.D., Editor-in-Chief.

An authoritative forum for the publication of original papers contributing to the advancement of surgery. Each issue contains information on the clinical application of new methods used in the management of patients; review articles with continuing education questions; condensed reviews of unusual case reports; "How I Do It" articles emphasizing the technical aspects of surgery.

Published monthly. Individual rate $49.00 per year (U.S.), $60.00 (elsewhere). Residents $32.00 (U.S. only).

Current Surgery

The Official Journal of the Association of Program Directors in Surgery

Lloyd M. Nyhus, M.D., Editor.

An internationally renowned editorial board prepares abstracts from every dependable source of surgical information throughout the world. Drawing on their own clinical experience and that of other recognized authorities, the members of the board provide commentary to further amplify and illuminate the material contained in each abstract. Also included are editorials, reports of new discoveries, residents' corner, and book reviews.

Published bimonthly. Individual rate $40.00 per year (U.S.), $46.00 (elsewhere). Residents $26.00 (U.S.), $32.00 (Canada).

Diseases of the Colon and Rectum

Official Journal of the American Society of Colon and Rectal Surgeons and the International Society of University Colon and Rectal Surgeons

Robert W. Beart, Jr., M.D., Editor-in-Chief.

This journal publishes reports on contemporary practice in the diagnosis and management of proctologic diseases and surgery. International in scope, it includes articles from physicians worldwide who share their important discoveries that offer new insights into basic research in metabolism, pathology, virology, radiology, and the clinical practice of medicine and surgery.

Published monthly. Individual rate $74.00 per year (U.S.), $89.00 (elsewhere). Residents $44.00 (U.S.), $59.00 (Canada).

Journal of Cardiovascular Surgery

Official Journal of the International Society for Cardiovascular Surgery

J. E. Connolly and S. S. Rose, Co-chief Editors.

The Journal is devoted to disease of the heart and the entire vascular system. It presents concise, informative coverage of the most significant work being done in diagnostic, experimental, and clinical surgery of the heart and blood vessels.

Published bimonthly. Individual rate $80.00 per year (North America only).

THROMBOSTAT™ (THROMBIN, USP), a trusted hemostatic aid, is now available in a pump spray form—permitting flexible and easy application. With the new THROMBOSTAT pump, you can achieve hemostasis in seconds over large body surface areas. Each depression of the pump offers an even distribution

SPRAY ON HEMOSTASIS

of THROMBOSTAT solution—allowing uniform hemostasis of the total area. The THROMBOSTAT pump is available in a convenient sterile kit that features a 20,000-unit vial of THROMBOSTAT (a practical size for procedures involving capillary bleeding), an appropriate measure of diluent, and a pump sprayer cap. The kit offers sterile packaging—permitting the entire contents to be brought directly into the sterile field. With the new THROMBOSTAT kit, it has never been simpler to control capillary bleeding.

Please see next page for brief summary of prescribing information.

THROMBOSTAT™ (THROMBIN, USP) (Bovine Origin)

Before prescribing, please see full prescribing information. A Brief Summary follows:

Thrombostat must not be injected! Apply on the surface of bleeding tissue as a solution or powder.

INDICATIONS AND USAGE: Thrombostat (Thrombin, USP) is indicated as an aid in hemostasis wherever oozing blood from capillaries and small venules is accessible.

In various types of surgery solutions of Thrombostat may be used in conjunction with Absorbable Gelatin Sponge, USP for hemostasis.

CONTRAINDICATIONS: Thrombostat is contraindicated in persons known to be sensitive to any of its components and/or to material of bovine origin.

WARNING: Because of its action in the clotting mechanism, Thrombostat must not be injected or otherwise allowed to enter large blood vessels. Extensive intravascular clotting and even death may result. Thrombostat is an antigenic substance and has caused sensitivity and allergic reactions when injected into animals.

PRECAUTIONS: General: Consult the absorbable gelatin sponge product labeling for complete information for use prior to utilizing the thrombin-saturated-sponge procedure.

Pregnancy—Teratogenic effects: Pregnancy Category C. Animal reproduction studies have not been conducted with Thrombin, Topical (Bovine). It is also not known whether Thrombin, Topical (Bovine) can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Thrombin, Topical (Bovine) should be given to a pregnant woman only if clearly indicated.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: An allergic type reaction following the use of Thrombostat for treatment of epistaxis has been reported. Febrile reactions have also been observed following the use of Thrombostat in certain surgical procedures but no cause-effect relationship has been established.

DOSAGE AND ADMINISTRATION: General: Solutions of Thrombostat may be prepared in sterile distilled water or isotonic saline. The intended use determines the strength of the solution to prepare. For general use in plastic surgery, dental extractions, skin grafting, neurosurgery, etc, solutions containing approximately 100 units per ml are frequently used. For this, 10 ml of diluent added to the 1000 unit package is suitable. Where bleeding is profuse, as from cut surfaces of liver and spleen, concentrations as high as 1000 to 2000 units per ml may be required. For this the 5000 unit vial dissolved in 5 ml or 2.5 ml respectively, of the diluent supplied in the package is convenient. Intermediate strengths to suit the needs of the case may be prepared by selecting the proper strength package and dissolving the contents in an appropriate volume of diluent. In many situations, it may be advantageous to use Thrombostat (Thrombin, USP) in dry form on oozing surfaces.

Caution: Solutions should be used the day they are prepared. The solution may be used for up to 6 hours when stored at room temperature; up to 24 hours when stored under refrigeration, and, if necessary, up to 48 hours when stored frozen.

The following techniques are suggested for the topical application of Thrombostat.

1. The recipient surface should be sponged (not wiped) free of blood before Thrombostat is applied.
2. A spray may be used or the surface may be flooded using a sterile syringe and small gauge needle. The most effective hemostasis results when the Thrombostat mixes freely with the blood as soon as it reaches the surface.
3. In instances where Thrombostat in dry form is needed, the vial is opened by removing the metal ring by flipping up the plastic cap and tearing counterclockwise. The rubber-diaphragm cap may be easily removed and the dried Thrombostat is then broken up into a powder by means of a sterile glass rod or other suitable sterile instrument.
4. Sponging of treated surfaces should be avoided in order that the clot remain securely in place.

Thrombostat may be used in conjunction with Absorbable Gelatin Sponge, USP as follows:

1. Prepare Thrombostat solution of the desired strength.
2. Immerse sponge strips of the desired size in the Thrombostat solution. Knead the sponge strips vigorously with moistened gloved fingers to remove trapped air, thereby facilitating saturation of the sponge.
3. Apply saturated sponge to bleeding area. Hold in place for 10 to 15 seconds with a pledget of cotton or a small gauze sponge.

Thrombostat Kit: Thrombostat Kit contains one sterile 20,000 unit vial of Thrombostat, one sterile vial of Isotonic Saline Diluent, and one sterile pump sprayer cap. The Kit may be used as follows:

1. Remove the Tyvek blister lid by pulling up at the indicated corner. The sterile inner tray can be lifted out or introduced into the operating field.
2. The cover to the sterile inner tray is removed by pulling up on the finger tab, exposing the sterile contents.
3. Thrombostat solution of the desired strength is prepared and the pump sprayer cap inserted and seated on the Thrombostat solution vial. Note: Several strokes of the pump sprayer will be required before the Thrombostat solution is expelled.
4. Alternatively, when Thrombostat in dry form is needed, the vial is opened as described above and the dried Thrombostat broken up into a powder by means of a sterile glass rod or other suitable sterile instrument.

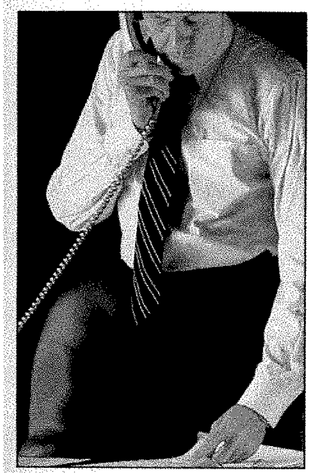
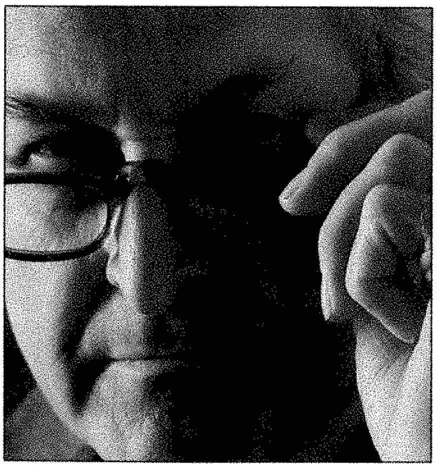
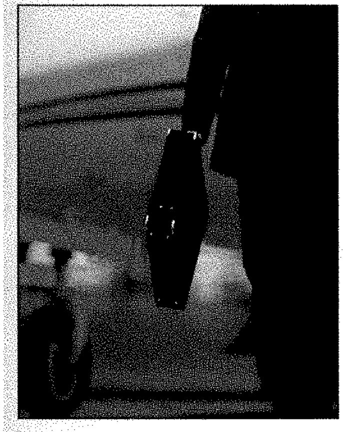
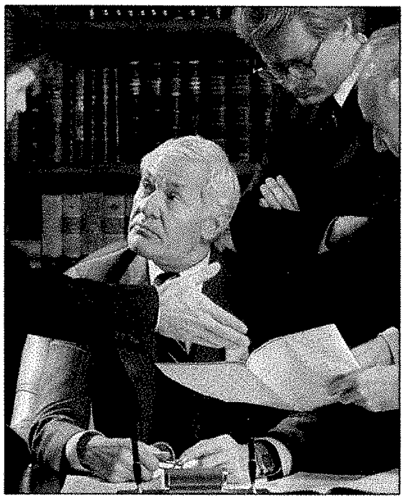
Do you really think he's going to sit still for a sitz bath?









Hemorrhoid Case Study #1

Patient: 56-year-old business executive.

Symptoms: Profuse rectal bleeding.

Diagnosis: Patient had undergone a hemorrhoidectomy ten years previously. Complete colonoscopy revealed normal findings except for the recurrence of several symptomatic Grade 2 internal hemorrhoids.

Treatment: Patient's travel and work schedule precluded compliance with prescribed treatment of sitz baths and suppositories three times a day. A decision was made to use ULTROID.™ Two 6-minute treatments at 16 milliamps were administered over a one-week period. Patient tolerated maximum milliamperage well and reported no pain during or after treatment.

Result: Patient reported no disruption to his work schedule or lifestyle. Subsequent postprocedure follow-up indicated no recurrence of symptomatic bleeding.

Hemorrhoids: A Problem Worth Solving.

The evidence is overwhelming. Every year 123,000 Americans undergo painful hemorrhoidectomies.[1] Millions more suffer from symptoms of itching, bleeding, and tissue prolapse through the rectum.

Patients with symptomatic hemorrhoids want immediate relief and a real solution.

ULTROID™: A Clinically Proven Solution.[2]

Now with ULTROID, Microvasive® introduces the future of nonsurgical hemorrhoid management. It is a monopolar, low-voltage treatment modality, clinically evaluated on hundreds of patients. ULTROID works biochemically at the feeding vasculature of the hemorrhoid's base. It leaves no visible ulceration or scarring.

ULTROID: Safe, Painless, and Effective.

ULTROID is the only modality that works on all four grades of symptomatic internal and mixed hemorrhoids. It works without cauterization, without burning. It can be used in your office, without special patient preparation or anesthesia. And, with ULTROID, patients experience no postprocedure pain or lifestyle disruption.

ULTROID: The New Treatment of Choice.

For more information on this new hemorrhoid treatment, our physician-moderated seminars, and product monograph, write or call our PHYSICIAN INFORMATION SERVICE, 800-225-3226.

Presidential Address: The Origin and Early Development of the Southern Surgical Association

JOHN L. SAWYERS, M.D.*

From the Department of Surgery, Vanderbilt University School of Medicine, Nashville, Tennessee

As we celebrate the one hundredth birthday of this association, it is appropriate to reflect on the origin of the Southern Surgical Association, which was founded in 1887. What was happening in the United States at that time? Grover Cleveland was President of the United States in 1887, and we had no Vice-President. Cleveland was confronted with a revenue surplus and asked Congress for tariff reductions. How President Reagan would envy that situation!

Cleveland keynoted the centennial celebration of the Constitution. Of interest to the South, President Cleveland ordered the war booty of the Union Army, consisting of captured Confederate flags, to be returned.

Yale had defeated Harvard in football and was considered the national football championship team. Oklahoma did not have a football team and was not even a state until 1907.

Men's clothing fashions were knickers with straw or bowler hats. Audiences were thrilled by Buffalo Bill's Wild West Show featuring Annie Oakley. Edison invented the motor-driven phonograph that played cylinder records. Other inventions included the player piano, the gramophone, and the first electrocardiogram. Table 1 compares life in the United States in 1887 with 1987. The gasoline-engine automobile was not yet in the United States—Daimler ran his first car in Germany in 1886. The first automobile in the U.S. was introduced in 1893 by Duryea. Airplanes were only a dream. Richard W. Sears, a former railroad clerk, and A. C. Roebuck, a watchmaker, developed an innovative form of mail order merchandising.

Discoveries and events occurring in 1887 in medicine are listed in Table 2.

At the time of these events, two brothers, W. E. B. Davis and J. D. S. Davis, founded this association in Birmingham, Alabama. Dr. W. E. B. Davis recalls the origin of "the Southern" in his Presidential Address given in 1902 at the fifteenth session of the Southern Surgical and Gynecological Association.[1] W. E. B. Davis and his brother were editors of the *Alabama Medical and Surgical Journal*. This journal was their first joint

venture. The journal was not successful, and publication stopped after 11 months. However, this journal stimulated the Davis brothers to propose a new medical society to be named the Alabama Surgical and Gynecological Association. The organizing meeting was held in November 1886 in the office of the *Alabama Medical and Surgical Journal.* The Davis brothers, conferring with a few prominent physicians from Birmingham, set December 15, 1886 as the organizational meeting date. Invitations were extended to fifty of Alabama's prominent physicians. The response was good.

Dr. H. N. Rosser of Birmingham was elected President and W. E. B. Davis was elected Secretary. In addition to Alabama physicians, 12 leading surgeons in the South were elected to honorary membership. Davis suggested this so that these prominent surgeons could serve as a nucleus to form a Southern association at a later date. Only one regular meeting was ever held—on October 11–12, 1887.

The Davis brothers, in their journal, had led an editorial attack regarding medical licensure in Alabama. The Davises proposed a single state medical licensing board; however, Dr. Jerome Cochran, who had organized the Alabama State Medical Association, favored a licensure of medical examiners in each county. Furthermore, the Davis brothers urged that only medical school graduates be eligible for licensure examination. Dr. Cochran was the most politically powerful figure in Alabama medicine. He opposed the proposed Alabama Surgical and Gynecological Association on the grounds that this new society might weaken the Alabama Medical Association. Dr. W. E. B. Davis went to Europe for 6 months in early 1887. His brother could not carry on alone the fight with Dr. Cochran.

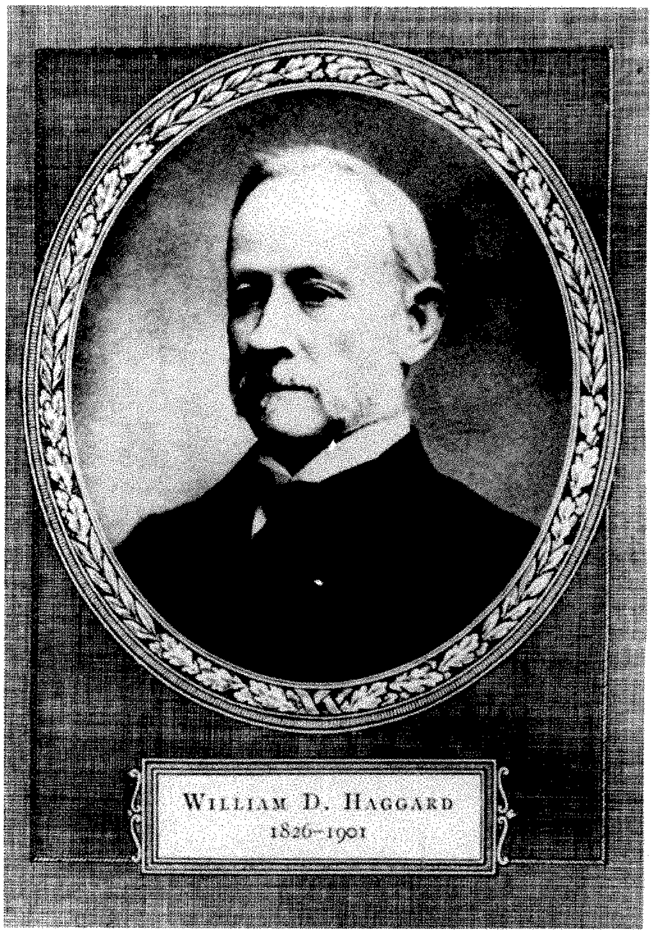

FIG. 1. W. D. Haggard—first president of the Southern Surgical and Gynecological Association, 1887–1888.

In March 1887, the Alabama Medical Society voted to continue the county examining licensure boards. The *Alabama Medical and Surgical Journal* was never published after May 1887. When W. E. B. Davis returned from Europe, he realized that the Alabama Surgical and Gynecological Association was in jeopardy with Cochran's opposition. Alternatives were discussed with the distinguished honorary members from outside Alabama. The decision was made to invite surgeons throughout the South to attend the October 1887 meeting with the idea of forming—instead of the Alabama Surgical and Gynecological Association—a new society to be named the Southern Surgical and Gynecological Association. Eighty replies were received in support of this idea. The Alabama Surgical and Gynecological Association met on October 11, 1887. On the second day of the meeting, October 12, 1887, the idea of forming the Southern Association was brought forth. Present was Dr. W. D. Haggard of Nashville, who argued eloquently in favor of a Southern organization (Fig. 1). The membership agreed. The Southern Surgical and Gynecologi-

W. E. B. Davis—Secretary
J. S. Cain—Chairman, Judicial Council
J. D. S. Davis—Chairman, Arrangements

cal Association was formed, with W. D. Haggard as President and W. E. B. Davis as Secretary. Dr. J. S. Cain of Nashville was elected chairman of the Judicial Council and J. D. S. Davis as chairman of the Committee on Arrangements (Table 3). As W. E. B. Davis writes: "The ablest men in the South, although absent, were elected to fill the other places on the Council." All promptly wired in their acceptance. Birmingham was selected as the next meeting place. The second Tuesday of November was the agreed-upon date; however, due to yellow fever, the meeting was delayed to December 4–6, 1888. By the time of this meeting, 90 members had been enrolled. The Southern Surgical Association was born.

The Davis Brothers

Who were these Davis brothers who at such a young age (24 and 28 years old) managed to organize this distinguished surgical organization?

William Elias Brownlee Davis

William Elias Brownlee Davis (Fig. 2) was born on November 25, 1863 in Trussville, Alabama. His father, Dr. Elias Davis, joined the Confederate Army and was killed while commanding sharpshooters at Petersburg, Virginia, before William Davis' birth.[2] William Davis represented either the third or fifth generation of physicians in the family. Carmichael[2] writes "third generation," whereas Moore's[1] article states "fifth." Davis' grandfather, Dr. Daniel Elias Davis, was an early settler of Alabama. William Davis had a brother, John D. S. Davis, who was 4 years older. Their widowed mother was a strong woman who, without the assistance of a husband, overcame the devastation caused by the war and raised her sons on a farm in Jefferson County, near Trussville, Alabama.

William Davis was educated in the schools at Trussville. He was considered the best student in Trussville High School. His grade average was 99.5%, the highest ever recorded in the school's history. He was able to enter directly into the junior class at the University of Alabama. Accomplishments at an early age marked his career. He decided to follow the family tradition of medicine. His medical education was unique even for those days, as he studied medicine at Vanderbilt University, the University of Louisville, and then Bellevue Hospital Medical College. His medical degree was obtained from Bellevue when he was 21 years old. He then returned to Alabama to join his older brother in practice.

FIG. 2. William Elias Brownlee Davis—founder of the Southern Surgical and Gynecological Association.

The Davis brothers worked together as a team in their endeavors. In 1894, William Davis and his brother—along with nine other men—established the Birmingham Medical College. William Davis assumed the position as Professor of Gynecology and Abdominal Surgery, only 10 years after graduating from medical school. He maintained this position until his death. John Davis was named Professor of Surgery.

That same year, 1894, the first hospital in Birmingham was started by the Davis brothers. This hospital was established to care for "women and surgical cases" and had a resident physician (Fig. 3).

Today, William Davis would be termed an "entrepreneur." He and John Davis founded a medical school that was the first in the country to provide an experimental surgery laboratory, a local hospital, a state medical journal, and organized the Southern Surgical Association. The Davis brothers collaborated on their experimental work, and credit was given to both for two notable investigations that were performed in the dog laboratory of the Birmingham Medical College. The Davis brothers reported their experience with 200 intestinal anastomoses performed in dogs. They demon-

strated that suture anastomosis was better than anastomosis by mechanical devices. Many debates ensued with surgeons who used the Murphy button. The second major accomplishment from their "dog lab" demonstrated the advantage of transperitoneal drainage of the common bile duct rather than suture closure after choledochotomy, which was standard practice at that time. Dr. W. J. Mayo praised the Davis brothers for this work.

TABLE 4. *Surgical Organizational Positions Held by W. E. B. Davis*

Year	Position
1886	Secretary, Alabama Surgical and Gynecological Association
1887–1900	Secretary, Southern Surgical and Gynecological Association
1901–1902	President, Southern Surgical and Gynecological Association
1889	Chairman, AMA Section for Obstetricians and Gynecologists
1890	Chairman, AMA Section on Surgery
1891	President, Tri-State Medical Society of Alabama, Georgia, and Tennessee
1892	President, American Association of Obstetricians and Gynecologists
1901	President, American Association of Obstetricians and Gynecologists
1902	Board of Censors, Medical Association of Alabama

The medical profession's duty to the public
Philosophy regarding the role of a surgeon

* Modified from Carmichael.[2]

William Davis served as the first Secretary of the Southern Surgical and Gynecological Association and maintained this position for 14 years. In 1901, he was elected President. His talents were recognized by other organizations. He served as President of the Tri-State Medical Society of Alabama, Georgia, and Tennessee. Other offices held were chairman of the Section for Obstetrics and Diseases of Women for the American Medical Association and the next year, 1890, chairman of the Section on Surgery (AMA). He later was elected Vice-President of the American Medical Association. He was also President of the American Association of Obstetricians and Gynecologists in 1901 (Table 4).

Carmichael[2] lists his published scientific contributions, which included biliary surgery, intestinal anastomosis, management of bullet wounds of the abdomen, postoperative abdominal care, and treatment of inflammation of the colon (Table 5).

W. E. B. Davis was described as "fearless, saying always what he believes to be the truth. His motto was 'Defend the right, and denounce fraud whenever found.' " He believed in high standards and, as Secretary, ran "the Southern" in this manner. When the Southern Surgical and Gynecological Association was founded in 1887, Davis accepted the office as Secretary but was also made chairman of a committee empowered to select suitable members for the Association. All those who accepted membership and paid dues were enrolled as Founder members. Davis believed that there were few men in the South of great reputation compared to those from cities in the North and East. Therefore, Davis invited "men of great eminence from the entire country to join the Association." This made "the Southern" a national organization from its beginning. Today, about one fourth of the membership resides outside the South. However, Davis had to admit as Founding Members all the members of the Alabama Association who desired to join "the Southern." To quote him: "This necessarily admitted some members who should not have been received into the enlarged organization. It took several years to overcome this unfortunate complication." Davis solved this dilemma by not publishing the names of these "undeservable members" in the *Transactions* when they resigned or died. In his Presidential Address, Davis wrote "It would have been peculiarly unfortunate to have had the sketch of the life of an unknown man in Alabama appear in the *Transactions,* which would have been read by many eminent surgeons who would have judged the Association by this example. However, by tact on the part of the Council and Secretary, these men have gradually disappeared from the roll, having been dropped as a rule for non-attendance or the non-payment of dues, there being a By-Law which provides that a member who fails to attend for three consecutive meetings shall be dropped from the roll and another that a member failing to pay his dues for one year shall be dropped." Thus did Davis ensure the high standards that have existed for one hundred years for membership in the Southern Surgical Association.

Three months after his Presidential Address to "the Southern," William E. B. Davis was killed at a railroad crossing in Birmingham. Coroner W. D. Paris investigated the death and reported:

> "The death of Dr. Davis was an accident, pure and simple.
> "When Dr. Davis approached the crossing the flagman waved his red flag and Dr. Davis stopped his horse upon nearing the track on which the Alabama Great Southern train was passing. As he came to a stop he turned the horse to the left, facing the east. There was a space left between the horse and the moving train, and while the train was passing Dr. Davis got out of his buggy and went to the horse's head, going between the horse and the train.
> "When he reached the head of the horse, he caught the bridle and at the same time his foot was caught in one of the rails of the track next to that upon which the train was moving. He gave his foot a sharp jerk to release it, and as the member was released he lost his balance and fell under the train.
> "I saw all of the witnesses who could be reached, and after a full and careful investigation my official decision is that Dr. Davis met his death by accident. Neither he nor the railroad company was responsible for the affair."

Dr. W. E. B. Davis is buried in Oak Hill Cemetery in Birmingham.

The Southern Surgical and Gynecological Association held a series of eulogies at their next meeting. The Council appropriated funds ($2,000) for a monument to Davis.

The Davis Statue

The Southern Surgical and Gynecological Association commissioned Giuseppe Moretti to cast in French bronze the statue of W. E. B. Davis. Moretti, who was born in Siena, Italy, lived in Budapest and had achieved fame for his bust of the Austrian emperor Franz Josef. In 1888, Moretti emigrated to the United States and moved to Pittsburgh where he made several sculptures for Highland Park. His third commission after arriving in Pittsburgh was a statue of Cornelius Vanderbilt, which graces the campus of Vanderbilt University in Nashville.

Moretti's most famous work is Vulcan. The city of St. Louis invited Birmingham to exhibit at their Louisiana Purchase Exhibition in 1904. The Commercial Club in Birmingham engaged Moretti to cast an iron statue of the mythical god of fire and forge, Vulcan, from Alabama iron. Vulcan is the largest cast iron statue in the world, measuring 55 feet from spear tip to toe. The statue won the grand prize of the exposition. Vulcan now resides on a pedestal atop Red Mountain in Birmingham. Moretti moved to Birmingham after his success with Vulcan. His first commission in Birmingham was the W. E. B. Davis statue.[3]

On Wednesday, December 14, 1904 at 11:00 A.M., the Davis statue was given to the City of Birmingham. The public was invited to the unveiling and thousands attended. The procession began at City Hall and included Birmingham city officials, the Cadet Corps of Howard College, Memoli's Band, a detachment of the Alabama National Guard, and members of the Southern. Reverend L. S. Handley opened the ceremony with a prayer. Dr. William D. Haggard of Nashville was master of ceremonies. Dr. Davis' two young daughters unveiled the nine foot high bronze statue, which Charles M. Rosser of Dallas presented to the city. The Honorable John C. Forney accepted the statue for the City of Birmingham and Dr. R. M. Cunningham, acting Governor, accepted for the State of Alabama.

In 1952, it was noted that Davis' statue was tilting, not unlike the Leaning Tower of Pisa. Under the chairmanship of Dr. Joseph M. Donald (SSA President, 1961) and James M. Mason (SSA President, 1930), a committee of the Jefferson County Medical Society arranged for the statue to be relocated near the Hillman Building at the University of Alabama Medical Center. On November 4, 1957, the rededication ceremonies were held with Dr. George Finney, Secretary, and Dr. Floyd McRae, President of the Southern Surgical Association, making remarks. Dr. Robert C. Berson, Vice President, University of Alabama Medical Center and Dean of the Medical College, accepted the statue and promised that no tilting would be allowed on the medical college grounds. The statue was again unveiled by Davis' two daughters, Mrs. Elizabeth Batchelder of Warrenton, VA, and Mrs. Margaret Davis of Birmingham.

The statue bears this inscription at its base: "He would have been known to the world as a patriot had he not been known as something greater—a physician."

Gertrude Davis

William Davis' wife, Gertrude Mastin Davis (Fig. 4), was as interested in "the Southern" as her husband. She

FIG. 4. Gertrude Mastin Davis—W. E. B. Davis' wife and Honorary Fellow of the Southern Surgical Association.

attended most meetings and helped edit the *Transactions*. Gertrude Davis attended meetings of the Association after her husband's untimely death, and in 1931 was elected an Honorary Fellow of the Southern Surgical Association. She attended meetings until 1950 and died in 1953. During the first 100 years of "the Southern," she was the only woman to be elected to membership.

John Daniel Sinkler Davis

The older Davis brother, John Daniel Sinkler Davis (Fig. 5), was less outgoing than William. He was born in Trussville, Alabama on January 19, 1859 and was educated in the local schools. He graduated from the Medical College of Georgia in 1879. For two years he practiced general medicine in Ferryville, Alabama and then set up his office in Birmingham. He made friends with the coroner and undertaker, which enabled him to perform a large number of autopsies and to secure cadavers for dissecting purposes. This prepared him for the successful experimental surgical work that he and William did in later years. Of the two brothers, John was the one who pioneered in experimental surgery. One of his studies concerned gunshot wounds of the heart in dogs. He utilized cardiac massage and wrote that animals "apparently dead for an hour could be resuscitated by massage or kneading the heart between finger and thumb."[4] In 1893 he advocated early operation for head injuries with depressed skull fractures. He utilized plaster of Paris for fractures and performed open reduction of long bone fractures using silver bone plates.

J. D. S. Davis was more reserved than his younger brother but was described by his peers as a "great student, untiring original investigator in establishing fundamental surgical principles, teacher, organizer, leader and surgeon—a man of rare charm, culture and skill."[5]

When the Davis brothers established the Birmingham Medical College (Fig. 6), John D. S. Davis was appointed Professor of Surgery. When this institution was merged into the University of Alabama, he became Professor of Surgery at that medical school.

Truly Yours, J. D. S. Davis

FIG. 5. John Daniel Sinkler Davis—co-founder of the Southern Surgical and Gynecological Association.

John Davis never held an office in "the Southern," but he was made an Honorary Fellow when the Association changed its name in 1916 to the Southern Surgical Association, dropping the words "and Gynecological."

Like his brother, John D. S. Davis died as a result of an accident. He was involved in an automobile accident and died of complications from his injuries in 1931.

The 1888 Meeting

At the organization meeting of 1887, it was decided that the next meeting would be held in Birmingham. Dr. William David Haggard had been elected President of the newly formed Southern Surgical and Gynecological Association. Dr. Haggard was Professor of Gynecology and Diseases of Children, Medical Department, the University of Tennessee, then located in Nashville. The Chair held by Dr. Haggard had been established by Dr. Paul F. Eve and W. K. Bowling. He called the first annual meeting to order at the civilized hour of 10 A.M. on December 4, 1888, in the hall of the Young Men's Christian Association. Forty-one of the 90 members were in attendance, with 50 visitors.

The meeting was opened by an eloquent prayer by the Reverend Dr. D. I. Purser of Birmingham (Fig. 7). This custom of opening the meeting with a prayer was reinstated today by Dr. Raymond Ramage.

The Reverend Dr. Purser had an unusual background. He was born in Copiah County, Mississippi, December 24, 1843. He was raised on a farm. At the age of 17 years he joined the Confederate Army and served with an artillery company in 16 engagements. After the war, he entered business and rapidly made enough money to become financially independent. In 1870, he entered the ministry but never accepted a salary. In 1884, he accepted the call from the First Church, the only white Baptist Church in Birmingham. The membership increased from 278 to 500. Not only did he develop his own church but established four other Baptist churches, often using his own funds.

His first wife died in 1879. He married Sallie Moody of Tuscaloosa in 1883. She was the daughter of Judge Washington Moody, a man of great wealth and influence. Her brother, Frank Moody, was President of the First National Bank in Tuscaloosa. An energetic woman, she taught Sunday School and helped advance her husband's ministry.

Dr. Purser was described as a sensational, evangelical preacher. To this comment he replied "Sensation is better than stagnation."[6]

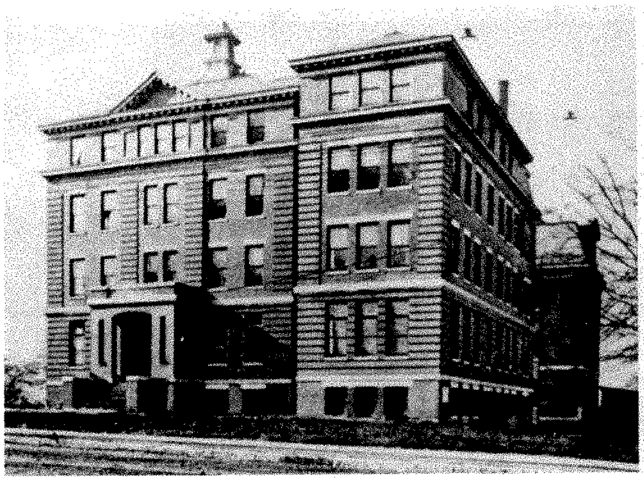

FIG. 6. The Birmingham Medical College, established by the Davis brothers in 1894, was merged into the University of Alabama Medical Center. The building as it appeared in 1903.

The Honorable A. O. Lane (Fig. 8), mayor of Birmingham, delivered a welcoming address, which is published in Volume I of the *Transactions*. Secretary Davis is reported to have remarked "It was the most beautiful welcoming address that I have ever listened to in my life."[7]

The Secretary then read a synopsis of the published minutes of the meeting for a permanent organization. A

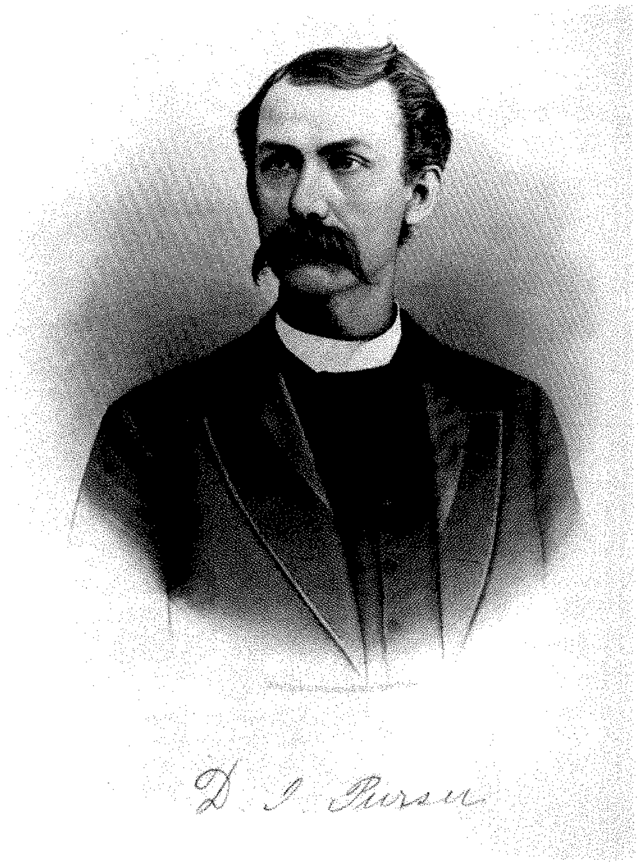

FIG. 7. Reverend Dr. D. I. Purser, whose eloquent prayer opened the first scientific session of the Southern Surgical and Gynecological Association in Birmingham, 1888.

FIG. 8. A. O. Lane, mayor of Birmingham, who delivered the welcoming address at the first scientific session of the Southern Surgical and Gynecological Association in Birmingham, 1888.

report was given by Dr. J. D. S. Davis, chairman of the Committee on Arrangements. Dr. Haggard appointed four members to serve on the Judicial Council with Dr. J. M. Taylor of Mississippi (the only member of the Council present). A motion was made to limit the membership in the Association to one hundred. This was referred to the Judicial Council, which reported back the next day that in its opinion it would not be wise to limit the membership to any specific number, and that the intent of the resolution could be attained in another and better way, by recommending that the standard of requirements for membership be fixed so high that only the best men would be eligible.

Dr. Haggard's Presidential Address praised J. Marion Sims for his contributions to gynecology and credited Ephraim McDowell for the founding of abdominal surgery. Haggard states that "The outcome of the labors of these two remarkable men in beneficient results has no parallel in the annals of medicine. They conferred on America the honor of being the birthplace of Gynecology, and did more to alleviate the sufferings, restore the health and prolong the lives of women than any two men living or dead." He then eloquently stated the need for the Association and welcomed into membership those "men as have by their works entitled them to the distinction of being educated, talented and industrious workers in the field of scientific research." His concluding remarks pointed out the trend toward specialization, emphasizing the danger of surgeons becoming deficient in the fundamental principles of medicine as a whole but supporting the trend toward specialization as exemplified by Sims' achievements.

The first scientific paper on the program was given by W. B. Rogers from Memphis, Tennessee. Entitled "On the Operation of Gastrostomy, With a Report of a Successful Case," Rogers presented a patient with a lye stricture of the esophagus. He had brought the patient with him and demonstrated the gastrostomy through which food was introduced through a silver tube. A mortality rate of 29.47% for gastrostomy performed for cicatrical stricture of the esophagus had been reported by Samuel W. Gross. The surgeons present were greatly interested in Rogers' successful result. He wrote that gastrostomy was indicated to prevent starvation but warned against using gastrostomy for patients with malignancy, stating "life can, at best, only hope to be prolonged for a very brief space—the wolf only driven from the door, while the jackal within devours the household."

Eighteen scientific papers were presented in addition to the Presidential Address. Eleven other papers were read by title. All papers were published in the *Transactions,* Volume I. Perhaps the most interesting paper was given by John R. Page, former Professor at the University of Virginia, entitled "Shock of Injury." This paper would probably have won the Shipley award, if an award had been given. Page described four young men seriously injured in railroad accidents. All survived despite a loss of consciousness and evident shock. One patient fell 52 feet from a train trestle, the second and third patients fell with their engine through a trestle 25 feet into a creek bed; five coal cars tumbled in on the engine. The fourth man was severely mashed between two railroad cars while attempting to couple them. After transporting the patients to a nearby hospital, Page performed suture of lacerations and cleansing of contusions and abrasions, but no other operation. He avoided bloodletting and sedation early after injury. General supportive care, bed rest, evacuation of the urinary bladder by catheter, morphine for pain, and nutritive enemas resulted in recovery of all four patients.

In the evening the members attended the opera house for musical entertainment and an annual oration by W. F. Hyer, ex-President of the Mississippi State Medical Association. Hyer spoke about the relationship that exists between the physician and his patient. This speech is published as the last article in Volume I of the *Transactions.* On the last day of the meeting the rules of the

Association were temporarily suspended, whereupon Dr. Rogers moved that Article XV of the By-Laws providing for an annual oration be stricken out. The motion passed without dissent. Perhaps it was the late hour. At any rate, Dr. Hyer's oration was the first and the last presented to the Southern Surgical Association.

At this meeting, Hunter McGuire of Richmond was elected President. Dr. McGuire was not present but wired his acceptance. Hunter Holmes McGuire's presidency ensured the success of the Association. He was a nationally recognized leader. He served as President of the American Surgical Association in 1886 and President of the American Medical Association in 1893. As John W. Long wrote in his Presidential Address in 1914, "No organization could fail to go when inspired by the enthusiasm of Davis, censored by the wisdom of Haggard, and vitalized by the magic touch of McGuire."[8] This trio was like the Ninth Wave. Our ancestors who lived near the ocean believed that there is always one wave that comes along that is larger than any preceding wave. This was called the Ninth Wave. This results from a remarkable combination of wind and sea. Special skill and time are needed to catch the Ninth Wave at its crest. Davis, Haggard, and McGuire—like the Ninth Wave—instituted significant change in surgery in the South. Their timing was perfect. The Southern Surgical Association rode the wave to the top during this past century.

Will the next hundred years be as fruitful? Arlie Mansberger, in his Presidential Address last year, illuminated some of the challenges that face us now: malpractice litigation, cost-restraining measures, DRGs, PROs, HMOs, PPOs, IPAs, physician reimbursement, turf battles, fragmentation, funding for graduate education and, indeed, medical education in general. Problems like these recall William French Smith's comments to incoming Attorney-General Edwin Meese. Smith remarked that some days Meese would feel like "the javelin competitor who won the toss of the coin and elected to receive."[9]

A glance backward at our history can only lead to optimism. The giants of Surgery have, are, and will be fellows of the Southern Surgical Association. Just as we have climbed forward on the shoulders of our past members, so shall we advance in the future. Hunter McGuire, in his Presidential Address, predicted that "this Society will become one of the most important in this country."[10] Indeed, it has. McGuire concluded his address with these words:

> "Gentlemen of the Southern Association, let our motto be lofty aim and united action. As Southern men, let us show to the world that, under changed conditions, we have still the stamina of our forefathers. As members of our beloved profession, let us strive to be first in scientific attainment, first in integrity, first in high purpose for the good of mankind."

I can conclude with no better words than those, so eloquently said in Nashville, Tennessee in 1889.

Renaissance Man of the Southern Surgical Association

GEORGE L. JORDAN, JR., M.D. and MICHAEL E. DEBAKEY, M.D.

From the Department of Surgery, Baylor College of Medicine, Houston, Texas

THE SOUTHERN SURGICAL ASSOCIATION met in many different cities during the late 19th century. The sixth meeting, held in 1893, was the first to be held in New Orleans. During the welcoming speech, Dr. A. B. Miles, the local arrangements chairman, noted that one of the outstanding institutions in New Orleans was Charity Hospital. This institution, which had been in operation since 1736, was the major teaching hospital for the University of Louisiana, which soon became Tulane University. The demonstrator in anatomy at Charity Hospital at the time of this meeting was Dr. Rudolph Matas, who, the following year, became professor of surgery at Charity Hospital and was appointed the Chairman of the Department of Surgery at Tulane University, succeeding Dr. A. B. Miles. At this first meeting attended by Dr. Matas, he participated in the discussion of a paper by W. T. Briggs on the treatment of bladder stones. Interestingly, the minutes of the meeting do not reflect Dr. Matas's election to membership, but he is listed as a member elected in 1893 in the *Transactions of the Southern Surgical and Gynecological Association* for 1894 and in all volumes of the *Transactions* since that time.

Dr. Matas was a native of Louisiana, born in Bonnet Carre in September 1860, the son of Dr. and Mrs. Narciso H. Matas, originally of Barcelona. He had a peripatetic childhood, moving as his family moved from place to place. His father, a physician, was engaged in investment activities in addition to his profession. During his formative years, Rudolph Matas lived in Barcelona, Spain, Paris, France, New Orleans, Louisiana, Brownsville, Texas, and Matamoros, Mexico. His formal education, therefore, was for short periods in many schools, but his remarkable intellectual capacity, his inquisitive mind, and his indefatigable energy were apparent at a very young age. He grew up as a multilingual young man, speaking English, French, Spanish, and subsequently Italian. Of equal importance, he read widely in all areas of knowledge. Thus, when he was graduated from St. John's Collegiate Institute in Matamoros, Mexico, he received prize copies of Jessup's *Botany*, Ganot's *Physics*, and Milne Edward's *Natural History* for leading his class in those subjects.

He had decided to follow in his father's footsteps in the profession of medicine and entered medical school at the University of Louisiana in 1877. On the basis of competitive examinations, he received an appointment as a resident medical student at Charity Hospital.

Dr. Matas was a man of irrepressible energy and vitality. Within a few years following his graduation, he had developed a rapidly growing private practice that claimed much of his time. In addition, however, he devoted a major portion of each morning to Charity Hospital as a visiting physician, and he fulfilled his editorial duties of the New Orleans Medical and Surgical Association. He organized a group that called itself the New Orleans Pathologic Society, composed of physicians trained and in training under Dr. H. D. Smith, a pathologist at Charity Hospital.

As is true of many such men, friends worried about his health. One friend stated that at the rate he was working he would plunge headlong toward a nervous or physical breakdown, and he was urged to decrease his activities. He, however, like some of his well-known successors, followed his own star and pursued goals which could not be denied.

Presented at the 100th Anniversary Meeting of The Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Submitted for publication: December 10, 1987.

When one recognizes the fact that his reading was always done at the end of a busy day or very early in the morning before starting another busy day, his motivation and commitment to the acquisition of knowledge was remarkable.

Dr. Matas's insatiable desire for knowledge led to the accumulation of a large personal library that he kept in his home. When one of us (MED) was a medical student, the personal library of Dr. Rudolph Matas served as an extension of the library at Tulane University, particularly his subscriptions to foreign journals. By this time his entire home had become one large library, and the weight of the books was so heavy that the foundation of the house had to be reinforced to maintain this weight. Requesting to use some of his collection for study, he invited me to his house. This courtly gentleman invited me in, gave me a glass of wine and asked many questions concerning my activities, my family, and my long-term goals. As I was leaving with the books that I borrowed, he invited me to join him on his front porch on Mardi Gras. He lived on St. Charles Avenue and the parade passed in front of his house. When they reached this house, they stopped to drink a toast to Dr. Matas.

Dr. Matas was a prolific writer. He was graduated from medical school at the age of 20 years, and at the age of 23 years was selected as editor of the *New Orleans Medical and Surgical Journal.* While its editor, he regularly wrote editorials and was recognized as a writer who not only had a great deal to say, but presented his material in an engaging and interesting manner. In 1935, Dr. W. H. Anderson stated that, "The catalogue of his publications . . . on the most varied subjects, attest to his tireless industry, his amazing versatility and unsurpassed erudition." His publications number more than 500, the last which I could identify was in 1953 at the age of 93 years.

When the Southern Surgical Association met in 1893 in New Orleans, Dr. Matas was recognized as the outstanding physician in New Orleans. It had been anticipated that Tulane would conduct a search for a new Chairman of Surgery from outside of Louisiana, but a ground swell of local support by the citizens at large, as well as physicians, assured his appointment to this post. There were publications in the local press in his support and poetry written in his honor.

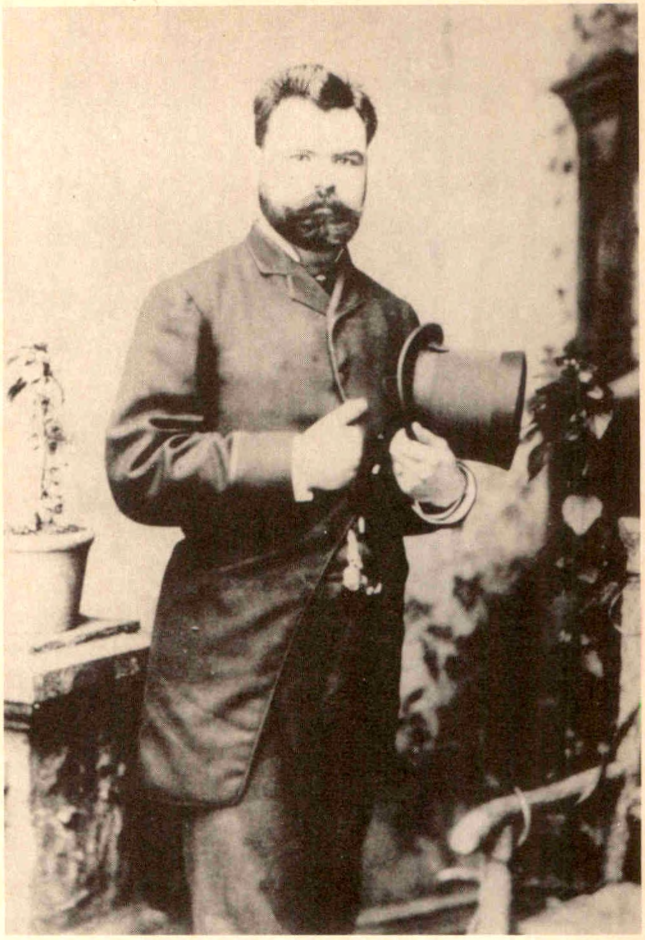

FIG. 1. A picture of Dr. Rudolph Matas circa 1884–85. (From Cohn I, Deutsch HB. Rudolph Matas. Garden City, NY: Doubleday and Co., 1960.

Under his leadership the Department of Surgery flourished. There were those who believed it impossible to begin a conversation on any subject about which Dr. Matas did not know more than those who introduced the conversation. One vignette involves an intern who had been searching for some obscure area of interest in which he might display his superior knowledge. He found such a subject in a Canadian medical journal and the next day engaged Dr. Matas in discussion. After listening to him, Dr. Matas commented that the subject he was discussing, and thoughts similar to those expressed by the intern, had been presented in a proprietory Canadian journal in its last issue, and referred the intern to this source if he wished to read further. Another student stated that if he attended Dr. Matas's lectures, operations, and rounds regularly, he did not need to read, because Dr. Matas would say all there was to say on all subjects.[1,2]

Dr. Matas served for 32 years as professor of surgery, stepping down as chairman of the department in 1927, when he was succeeded by Dr. Alton Ochsner. However, he continued to live in New Orleans until his death in 1957, just 3 years short of his one hundredth birthday. After retiring as chairman, he continued to operate, and performed his last operation on an 85-year-old patient in 1945 when he was 85 years old.

Dr. Matas attended the Southern Surgical Association on 22 occasions from 1893 to 1944, on the last occasion during his 84th year of life. He never attended without

being an active participant. He presented 17 original papers and 29 discussions. At many meetings he discussed more than one paper. In fact, in 1932 he rose to discuss papers on five occasions. His discussions were always detailed, extensive expositions of the subject at hand. In fact, some of his published discussions are equivalent in length to an original paper. The breadth and depth of his knowledge was truly astounding.

Dr. Matas was probably best known for his contributions to vascular surgery, and eight of his original presentations were on vascular subjects. He was one of the first to recommend wiring and electrolysis for the treatment of abdominal aortic aneurysms and presented a paper on this subject at the Southern Surgical Association in 1900. A major contribution was the technique of endoaneurysmorrhaphy, which he first performed in the treatment of a traumatic aneurysm of the brachial artery in 1888. The treatment of the aneurysm by the usual method of ligature of the artery proximal to the aneurysm failed and shortly thereafter he ligated the vessel below the aneurysm and hoped to complete its cure. The aneurysm rapidly returned to its original size and force of pulsation. At the time of reoperation he controlled the circulation in the area by an Esmarch bandage. He opened the aneurysmal sac and observed large collateral vessels, which he closed by suture. The patient's wounds healed without complication and he was known to be alive and performing hard manual labor many years later. Dr. Matas did not repeat this operation until 12 years later and it was first reported before the American Surgical Association in 1902. His first discussion of this subject at the Southern Surgical Association was in 1911 when he discussed a presentation by W. C. G. Kirschner entitled, "The Matas Operation in the Treatment of Traumatic Aneurysm." His extensive experience with endoaneurysmorrhaphy was presented at the Southern Surgical Association in 1919 when he presented "Endoaneurysmorrhaphy. I. Statistics of Operation of Endoaneurysmorrhaphy. II. Personal Experiences and Observations on the Treatment of Arteriovenous Aneurysms by the Intrasaccular Method of Suture with

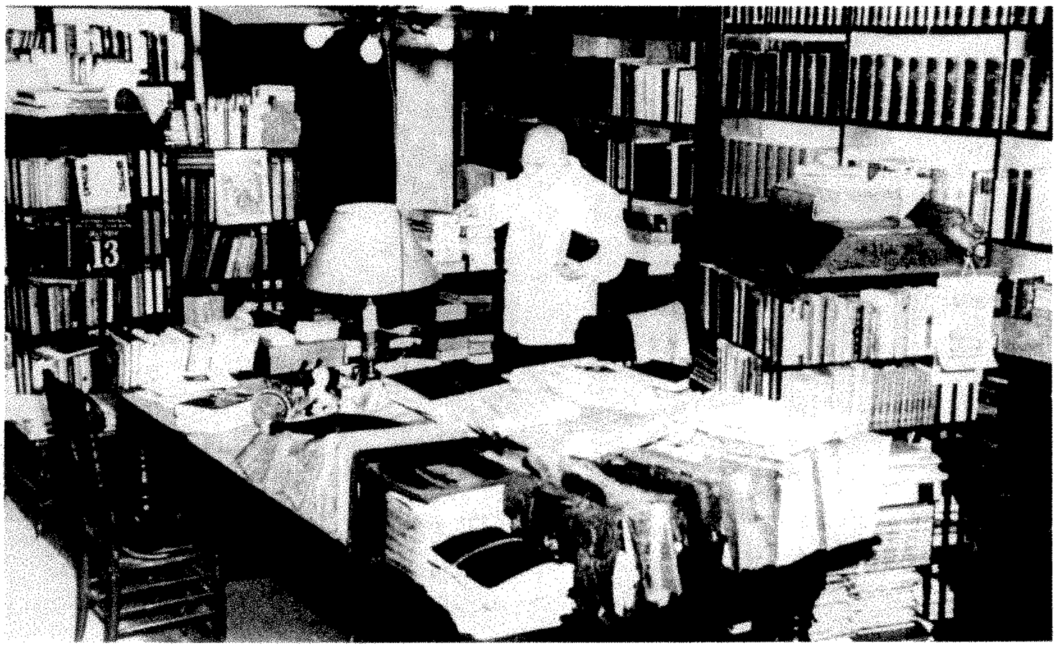

FIG. 3. Dr. Matas at home. Most of the rooms of his house were filled with books as shown here. (From Cohn I, Deutsch HB. Rudolph Matas. Garden City, NY: Doubleday and Co., 1960.

Special Reference to the Transvenous Route." By this time he was recognized as the premier vascular surgeon in the United States and subsequently he discussed papers on aneurysmal surgery on many occasions.[3]

Other vascular subjects on which he presented original papers include the systemic and cardiovascular effects of arteriovenous fistulas, a summary of his personal experience in the surgery of the subclavian artery, aneurysms of the Circle of Willis, and congenital arteriovenous angioma of the arm. He also discussed papers on lymphatic edema, mesenteric thrombosis, aneurysms of the temporal artery and later, aneurysms in the cervical portion of the internal carotid artery. At the last meeting he attended, at age 84, he discussed a paper by A. H. Blakemore and J. W. Lord, Jr., entitled, "A Nonsuture Method of Blood Vessel Anastomosis."

Although vascular surgery was the subject of many of his comments at the Southern Surgical Association, he presented papers on biliary tract disease, extra-uterine pregnancy, hair balls of the stomach, and trigeminal neuralgia, and discussed a variety of other subjects, including appendicitis, cystectomy for carcinoma of the bladder, hypodermoclysis, injection of the Gasserian ganglion for neuralgia, pseudomyxoma peritonei, ptosis of the spleen, scalenus anticus syndrome, and spinal and avertin anesthesia.[4-20]

In 1899, Dr. Matas presented a paper on the history and methods of intralaryngeal insufflation for the relief of acute surgical pneumothorax, with a description of the latest devices for this purpose. He was one of the first to use endotracheal intubation and positive pressure respiration in operations on the thorax. In the early 1900s he became interested in the administration of fluid and electrolytes and is credited with the first use of intravenous fluids (Table 1).[6]

Dr. Matas was elected to the office of President of the Southern Surgical Association and served in this capacity in 1911. He presented another innovative idea whose time had come. His presidential address was entitled, "The Cinematograph as an Aid to Medical Education and Research." His lecture was illustrated by moving pictures of ultramicroscopic life in the blood and tissues, as well as of surgical operations, and he demonstrated graphically the value of motion pictures as an educational tool. This idea, of course, rapidly became popular and since that time pictures on celluloid film or videotape have become standard instructional tools in all areas where dynamic action photographs can depict the subject at hand.[10]

He was an active member of the Southern Surgical Association for 34 years and was elected to honorary membership in 1927. He continued to attend meetings of the Association and to participate in the scientific activities for an additional 17 years.

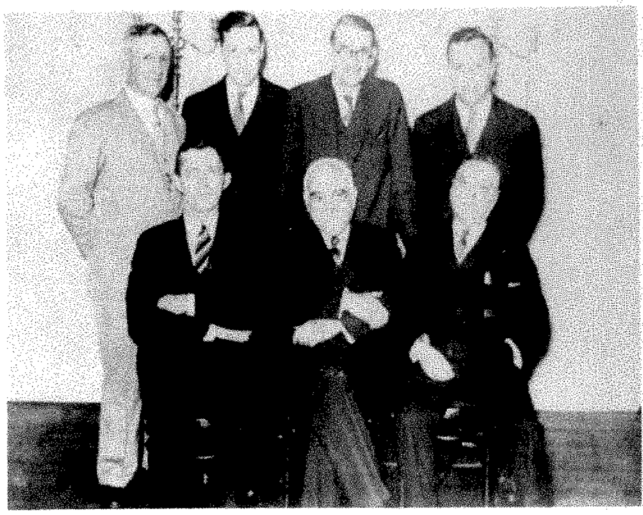

FIG. 4. Dr. Matas at the time of the presentation of the first Matas Award for Vascular Surgery. Seated at his right is Dr. Mont Reid, recipient of the first award. Others in the picture are Mike Hart, Dr. Lucian H. Landry, Dr. Emile Block, Dr. Isidore Cohn, and Dr. Alton Ochsner. (From Cohn I, Deutsch HB. Rudolph Matas. Garden City, NY: Doubleday and Co., 1960.

He was deeply concerned about our profession and one of his publications is entitled, "The Soul of the Surgeon," which appeared in the Transactions of the Mississippi State Medical Society in 1915. He spoke out strongly against quackery, fee splitting, and unnecessary surgery.

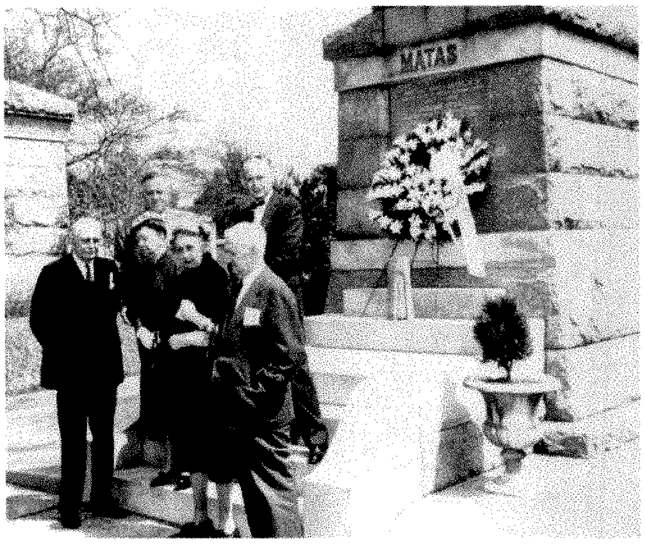

FIG. 5. A photograph of the Matas tomb during a meeting of the International Anesthesia Society in 1958. This meeting was dedicated to Dr. Matas. The individuals on the front row are Dr. Isidore Cohn, Mrs. M. C. Mehan, Mrs. Lucian (Bernice) Landry, and Dr. Lucian Landry. On the back row, Dr. Harold R. Griffith, and Dr. John Adriani. (From the private collection of Dr. Isidore Cohn, Sr., published with permission from Dr. Isidore Cohn, Jr.)

TABLE 1. *Significant Contributions of Rudolph Matas, M.D.*

1. Father of modern vascular surgery
   - a. First endoaneurysmorrhaphy
   - b. Treatment of an aortic abdominal aneurysm by wiring and electrolysis
   - c. Ligation of abdominal aorta
   - d. An aluminum band for compression of arteries
   - e. Emphasis on systemic effects of arteriovenous fistulae
   - f. Studies of venous disease
   - g. Emphasis of role of edema in erysipeloid infections
   - h. Classic paper on elephantiasis
   - i. Performed the first Kondoleon operation in the Western Hemisphere
2. First to use intravenous saline solutions in surgical patients
3. First to advocate gastric drainage with indwelling tube introduced through the nose
4. Laboratory studies on positive pressure respiration for open thoracic operations
5. Pioneer in local anesthesia
6. Contributions to the solution of the yellow fever problem
7. Use of motion pictures for instructional purposes

In all the study of the life of Rudolph Matas, only two negative comments were encountered. First, it was noted that he often failed to meet deadlines for publications set by others. For example, Dr. Cohn stated that the manuscript originally scheduled to appear in Volume I of *Keen's Surgery,* which was published in 1906, was finally sent in time for inclusion in the 5th edition, which was published in 1909. Dr. Matas was asked to prepare a history of medicine in the State of Louisiana in 1926. By 1948, Dr. Matas had accumulated a trunkful of documents and manuscripts, but had not completed the task because in preparing the material from Louisiana he found that this had to relate to medicine within the United States, and this had to relate to medicine in the world. This history was ultimately completed by a historian, Dr. John Duffy, who was employed by Dr. Matas, and was published in two volumes, Volume I in 1958, the year after Dr. Matas's death, and Volume II in 1962.[21] The second negative statement concerns his discussion at scientific meetings where the extent of his knowledge and understanding of a subject led to lengthy discussions that usurped the time of other individuals on the program.

TABLE 2. *Rudolph Matas: Elected Offices in Professional Societies*

President	New Orleans Medical and Surgical Association
President	Louisiana State Medical Society
President (Honorary)	Pan American Medical Congress
President	American Surgical Association
President	Southern Surgical Association
President	American Society for Thoracic Surgery
President	American College of Surgeons (Founding Member)
President	International Society of Surgery
Vice President	American Society of Clinical Surgery
Vice President	American College of Surgeons
Vice President	American Medical Association

Dr. Matas belonged to most of the major surgical associations during his lifetime, and held elective offices in many (Table 2).

Dr. Matas received 29 foreign decorations from Peru, England, Italy, Cuba, Denmark, France, Mexico, Poland, Venezuela, Belgium, and Greece, and 11 specific honors from Spain.

He was awarded honorary degrees from Washington University in St. Louis, The University of Pennsylvania, The University of Alabama, Tulane University, Princeton University, and the University of Guatemala. In fact, Cohn and Deutsch list 94 "degrees, honorary awards, foreign decorations, and official positions."

When I (GLJ) had the privilege of meeting Dr. Matas in New Orleans, he was 87 years old. He still attended functions held at Tulane University School of Medicine and it was apparent that the regard in which he was held by those audiences bordered on reverence. It was not unusual for Dr. Matas to enter the auditorium after the entire assemblage had gathered. On those occasions, Dr. Alton Ochsner would leave the podium, go to the rear of the auditorium, and personally escort Dr. Matas to his seat. As Dr. Matas proceeded down the aisle, the entire audience rose spontaneously and remained standing until Dr. Matas was seated. The support and adulation of the City of New Orleans for this great man was evidenced in the 1880s and continued through a 70-year period until his death in 1957.

He received ten local honors. One of these was the establishment of the Rudolph Matas Award in Cardiovascular Surgery through the Violet Hart Fund. This prestigious award has been given to only 11 surgeons in the past 53 years. Seven of these 11 recipients, including Drs. Mont Reid, Daniel Elkin, Alfred Blalock, Michael DeBakey, John Gibbon, Harris Muller, and John Kirklin, were members of the Southern Surgical Association. In 1954, Dr. DeBakey and Dr. Emile Holman were the last to receive the award from Dr. Matas personally, when Dr. Matas was 94 years old.

Dr. Rudolph Matas is the classic example of what an individual can accomplish based on his native intelligence, imagination, motivation, and energetic pursuit of his goals. During his boyhood, his family life was extremely unstable with the ultimate divorce of his parents, despite a strict Catholic religious indoctrination, and finally there was alienation from his mother and sister, who made active attempts to be destructive. His many moves during childhood provided a poor climate for developing close friends. Some of the schools he attended were not stimulating, and had he not had his own insatiable desire to read and to learn, he might have been poorly educated. His family's financial position varied greatly from time to time, his father at times being successful in some of his investments and establishment of a practice, while at other times he was financially disadvantaged. While a medical student, his roommate, one of his closest friends, died within 24 hours after being stricken by yellow fever, despite Dr. Matas's extensive experience with this disease. He was unable to marry the girl he loved for many years, because she was married to another man, and even subsequently, when she was separated from her husband, their religion delayed their marriage. Their one child was stillborn and his wife preceded him in death by many years.

He was an extraordinary individual despite all of these negative influences. He was recognized by some internists as the best diagnostician in America, and according to Cohn, was the best surgeon of his time by Dr. Crile. He was a superior teacher. He loved his patients, and in return he was loved by his students and those with whom he came in contact, both socially and professionally.

The greatness of Rudolph Matas is eloquently expressed in statements by Dr. J. W. Lipscomb in 1915 and in a birthday volume produced in his honor in 1931:

> "The foremost man in the foremost college in this great Southland of ours, the Nestor of our brilliant and gifted profession. We have but to mention his name and his contemporaries throughout the United States stand at attention. Someone has said that, to be an ideal doctor, we must possess the wisdom of Solomon, the faith of Abraham, the meekness of Moses, the patience of Job, the charity of Dorcas, the eloquence of St. Paul, the bravery of Joshua, the strength of Samson, the executive ability of a Jezebel, must be a hunter like Nimrod, a fisher like Peter, a climber like Zaccheus, a driver like Jehu. He should be free of Asa's gout, the melancholy of Saul, the gastric infelicity of Timothy; have all the virtues of the most virtuous and the religion of all saints. All of these are his."[22]
>
> "He is a rare mixture of the Old World and the New. He is a citizen of the World. He is a towering figure in the world of medicine and of men. He has proved himself to be a chivalrous knight and at once a humble worker, a literateur, a dreamer, an original thinker and a thorough master of the art of surgery. His ways are modest, his motives pure."
>
> "When the influence of many of us will be scattered as grains of sand by the wind, Dr. Matas's influence will be as a beacon light across the storm-tossed sea in the life of many men. The rays of this light will continue to carry the message of devotion to duty, love of mankind, mercy to the needy and sick, and humility."[1]

The Role of Gynecologic Surgeons in the Southern Surgical Association

LAMAN A. GRAY, SR., M.D.

From the Department of Obstetrics and Gynecology, University of Louisville School of Medicine, Louisville, Kentucky

GYNECOLOGISTS have played a major role in the development and history of the Southern Surgical and Gynecological Association. A review of the Transactions over the past 100 years supports this statement. The organization of this Association was primarily the result of the foresight and energies of two young brothers, W. E. B. Davis and J. T. S. Davis, of Birmingham, Alabama. After completion of medical school in Nashville, Tennessee, the brothers returned to Birmingham in 1886. On December 15, 1886, the brothers formed a new state organization, the Alabama Surgical and Gynecological Association. H. N. Rosser was elected President and W. E. B. Davis was elected Secretary. Fifty leading surgeons of the state were invited to join.

In 1887, the brothers proposed that a broader organization be formed out of the Alabama Surgical and Gynecological Association, to be named the Southern Surgical and Gynecological Association. Representative surgeons from throughout the South were to be invited to join.

Surgery in the South

In the nineteenth century, surgery, especially gynecologic surgery, developed rapidly in the southern states. Knowledge of successful operations spread over this country and Europe. The demonstration that complicated operative procedures could be performed with low mortality resulted in a wide interest in surgical diseases in the abdomen.

The development of gynecologic surgery in the United States was stimulated by the dramatic contributions of Ephraim McDowell in Kentucky (1809) and J. Marion Sims in Alabama (1849).

In 1809, Ephraim McDowell,[1] in his home in Danville, Kentucky, removed a 22.5 pound ovarian cyst from Jane Todd Crawford. This successful operation, and 12 more to follow for ovarian tumors, signalled the beginning of abdominal surgery. For many years thereafter, laparotomy was performed principally for the removal of large ovarian cysts. Several surgeons in this country, especially the Atlee brothers of Philadelphia, and others in England (Lawson Tait and Spencer Wells) became famous after reports of large series of successful operations for ovarian cysts.

It is entirely fitting that the Southern Surgical Association chose to use a bust of McDowell as the central figure in its organizational insignia, which first appeared in Volume II of its Transactions for the year 1889.

In Montgomery, Alabama, J. Marion Sims[2] (1813–1883) reported the surgical cure of a patient with vesicovaginal fistula, a condition that had defied all previous surgical attempts to correct. Subsequently, Sims developed many other operative procedures, established the Women's Hospital in New York, and became famous as a surgeon in the capitals of Europe. He was especially interested in the surgical treatment of pelvic cancer. Because the disease often was considered contagious and likely venereal, and because Sims continued to treat pelvic cancer in the Women's Hospital of New York, he was removed from the staff at the insistence of the Board of Lady Managers, although he had been instrumental in the building of that hospital. This was a dramatic and historic confrontation.

Presented at the 100th Anniversary Meeting of The Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests and correspondence: Laman A. Gray, Sr., Department of Obstetrics and Gynecology, University of Louisville, Louisville, KY 40292.

Submitted for publication: January 18, 1988.

The accomplishments of the early intrepid surgeons remain a source of great pride to Southerners. Distinguished southern surgeons included Dudley, Eve, Emmett, and others.

Robert Battey,[3] (1828–1895) in Rome, Georgia, performed laparotomies for excision of ovaries in many patients from 1872 to 1893. His indications for oophorectomy are not acceptable currently. They included neurasthenia, headaches, mental problems, and insanity. His techniques were excellent and advanced the safety of laparotomy for other purposes, especially for various adnexal diseases. He also championed the vaginal approach for removal of the ovaries. He was an expert anatomist. He was President of the American Gynecological Society in 1899 but was never a member of the Southern Surgical Association.

Organizational Meeting October 12, 1887

The need for specialty surgical associations to disseminate information and to allow comparison of results among surgeons was evident by the end of the century. It was time for the birth of the Southern Surgical and Gynecological Association.

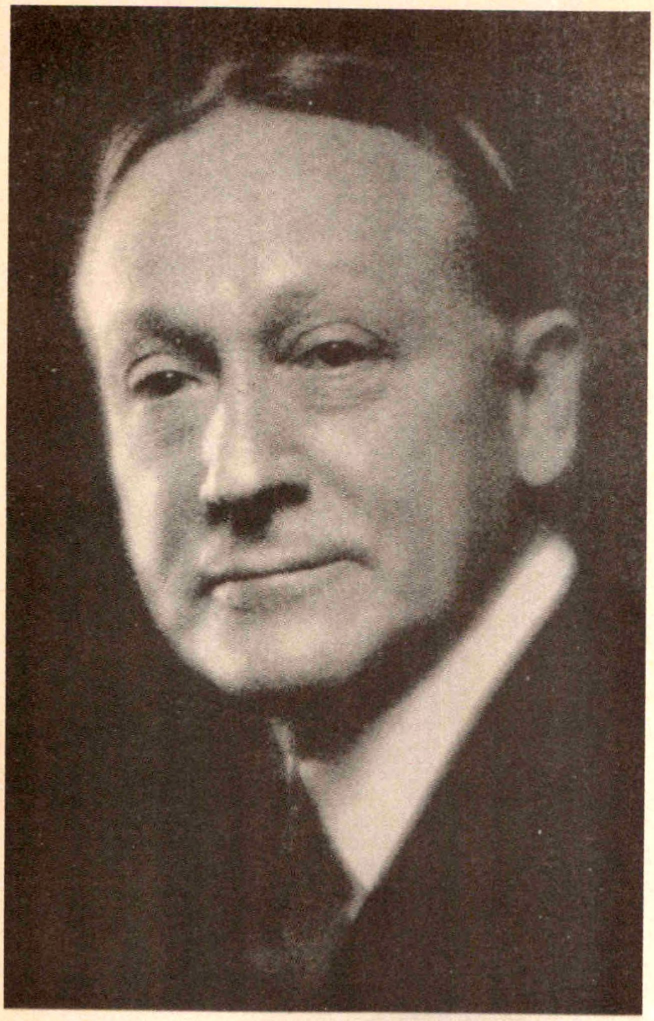
FIG. 1. Ephraim McDowell, forerunner of abdominal surgery, 1809.

James Marion Sims.

FIG. 2. J. Marion Sims, cure of vesicovaginal fistula, 1849, Gynecologic Surgeon from Montgomery, Alabama.

The mission of the proposed Southern Surgical and Gynecological Association was "to quicken the search and diffuse knowledge in relation to surgery and gynecology in the southern states." W. D. Haggard, Professor of Obstetrics and Diseases of Women in Nashville, advised his former student, W. E. B. Davis, that gynecology should be included. Davis described this undertaking in his presidential address in 1902.

> "When it was decided by some of the leaders of the Alabama Association to extend the organization, the honorary members were conferred with and they, with but few exceptions, approved of the plan. I remember that Dr. Yandell wrote me that he thought the union would prove rather an unsatisfactory one, as the general surgeon would not enjoy listening to a gynecologist discuss dysmenorrhoea, and the gynecologist would have very little interest in the treatment of a fracture of the thigh. Yet with so great a surgeon speaking disparagingly of it—and this was the first association where the surgeons and gynecologists were combined in this way—its name has anticipated what may be expected in the future. Indeed, purely gynecological societies will prove less frequent with each recurring year. After conferring with a large number of the members of the new organization, a letter signed by the President and Secretary was sent to representative men throughout the South, inviting them to attend the approaching meeting of the



William David Haggard, M.D.

FIG. 3. W. D. Haggard, Professor of Obstetrics and Diseases of Women, University of Tennessee, Nashville.

> Alabama Surgical and Gynecological Association, October 11 and 12, 1887, with a view of forming the Southern Surgical and Gynecological Association. They were asked to express their opinion of such an organization and to signify whether they would be willing or not to be placed upon its roll of members. There were about eighty favorable replies to these letters. Among those who expressed very great enthusiasm to see the organization as a truly representative Southern special society was W. D. Haggard, of Nashville, the father of our Secretary. He was very active in his efforts in behalf of the proposed organization. Indeed, his services were of inestimable value in the early history of the organization."

The organizational meeting was completed on October 12, 1887, despite the antagonism of some members of the Alabama Society. The Davis brothers had invited the southern members of the American Surgical Association (founded in 1880) and the American Gynecological Association (founded in 1876).* In addition to these, certain other prominent physicians were invited to the meeting in Birmingham. Only a few attended but 80 wrote letters of interest. The broad invitations later proved a source of embarrassment to the Secretary who had invited into membership physicians who were important, but many of whom were neither general surgeons nor gynecologists. However, the result was the enthusiastic formation of the new Association. W. D. Haggard was elected President and W. E. B. Davis was elected Secretary.

First Annual Meeting

At the first annual meeting of the Southern Surgical and Gynecological Association in Birmingham, on December 4, 5 and 6, 1888, 41 members and 50 visitors were present. W. E. B. Davis read a synopsis of the published minutes of the organization meeting of the previous year. Eighteen presentations were made at the first annual meeting, of which seven were related to gynecology and eleven to general surgery. Included were the following: (1) "Chronic Pelvic Cellulitis," (2) "The Medical Treatment of Fibroid Tumors of the Uterus," (3) "Floating Kidney, with Vicarious Menstruation," (4) "The Present Status of Electro-Therapeutics in Gynecology," (5) "Hysterectomy in Cancer of the Uterus," (6) "Laceration of Perineum and Rectocele," and (7) "Treatment of Certain Forms of Menorrhagia, with report of Cases."

The first President, W. D. Haggard (1888), was influential in forming and setting the course of the Association. His son, W. D. Haggard, Jr., was Secretary from 1901 to 1918, when he became President. The younger Haggard guided the Association with great foresight during his tenure as Secretary.

The Senior Haggard's Presidential Address (1888) stated:

> "Gynecic Surgery, with all its brilliant achievements, owes its present exalted position to the illustrious Sims, no less than Abdominal Surgery owes its origin to the world renowned McDowell. The outcome of the labors of these two remarkable men in beneficent results has no parallel in the annals of medicine. They conferred on America the honor of being the birthplace of Gynecology, and did more to alleviate the sufferings, restore the health and prolong the lives of women than any two men living or dead." . . .
>
> "The Southern Surgical and Gynecological Association did not spring voluntarily into existence, but was the outgrowth of necessity and the embodiment of unknown power."
>
> "It was the work of a few energetic minds and hearts that saw its need, and seized the opportunity to give it form and being, which was accomplished in this city the second Tuesday in September 1887, at a most auspicious moment, and under most favorable circumstances." . . .
>
> "This Association has now met for the first time since its organization to lay the offerings of another year's work on the altar of science, and to further consider the present state of surgery and gynecology, and to contribute its mite in promoting the advance-

---

* The 100th anniversary of the AGS was held in The Homestead Hotel, Hot Springs, Virginia, May 24–29, 1976.

> ment of each department as a pure science, and their perfection as practical arts."
>
> "None, perhaps, will question the supreme and commanding fact that in these two branches of medical science the greatest advances have been made."

Three classes of professional men were wanted for this Association: first, the specialist (a surgeon or gynecologist of distinction, skill, and experience); second, the general practitioner of eminence and experience, who in addition, practiced surgery and gynecology to a limited extent; and third, the young surgeon and gynecologist of character, talent, education, and promise, but whose practical experience was limited. In this connection, the term "promise" was considered most important.

At the conclusion of the first regular meeting in 1888, Hunter McGuire, of Richmond, Virginia, was chosen as President. His reputation was outstanding throughout this country and in Europe. During the War between the States, he was Medical Director of the Army of the Shenandoah under General Stonewall Jackson. He had been President of the American Surgical Association and American Medical Association. His selection as President was the rallying point to make the new organization a viable one.

Meetings 1888 to Date

The second session of the Association was held in Nashville, Tennessee, November 14–18, 1889. There were 19 presentations of which 14 were related to gynecologic surgery. There were five papers on general surgery.

At the third meeting of the Association in 1890, Lewis S. McMurtry, Professor of Gynecology at the University of Kentucky in Louisville, delivered a long paper entitled "Inflammation In and About the Head of the Colon." He discussed in detail the problems of appendicitis and the treatment by laparotomy. There was prolonged discussion. McMurtry was elected President of the Association for the coming year. Of 18 papers presented at this meeting, seven were on gynecologic subjects.

The following year, 1891, in his Presidential Address, McMurtry stated that within 15 years the entire practice of surgery had been revolutionized. New methods had been introduced and new regions invaded. The science and art of gynecology, which a few years previously was limited to a small and narrow field, had grown into a major branch of medical science. Formerly, it had been divided between midwifery and surgery, as a minor branch of one or both, but in recent years gynecology had become an independent and essential specialty.

McMurtry entered a protest against the perversion of the word "conservatism" when it was used to oppose and retard progress in surgery, the supreme purpose and object of which is "to preserve in a safe and entire state, or from loss, waste or injury." He stated further that one of the great advances of modern times is the knowledge acquired of the inflammatory diseases of the uterine appendages. More than a quarter of a century previously, two Frenchmen, Bernutz and Goupil, had described these lesions and their deadly effects.

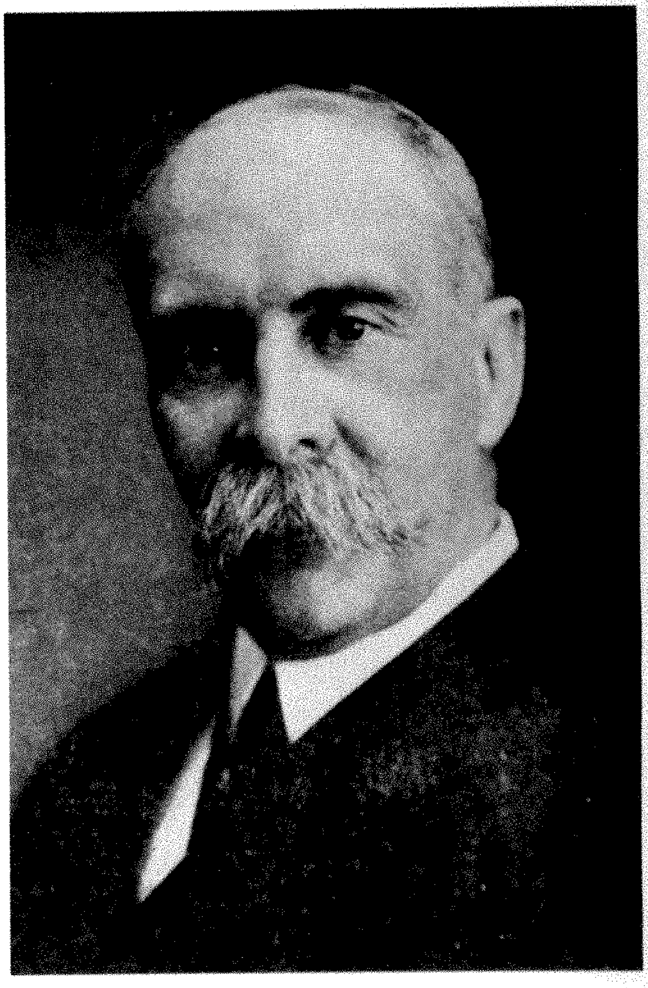


FIG. 4. L. S. McMurtry, Professor of Gynecology, Louisville, Kentucky.

At that time (1891) there were 130 members of the Association, of whom 30 were gynecologists. Of the 23 presentations, 11 were on gynecologic subjects.

At the seventh meeting in 1894, in the Presidential Address, Cornelius Kollock stated, "Our Association has the advantage of combining two specialties, surgery and gynecology. For the country doctor, away from large communities, the knowledge of both is almost imperative. In cities, gynecologists and surgeons may supplement each other's work, but in the country, the doctors cannot always go in pairs. Let our young physicians, especially those who seek a country practice, strive for the knowledge of both specialties; then there will be less

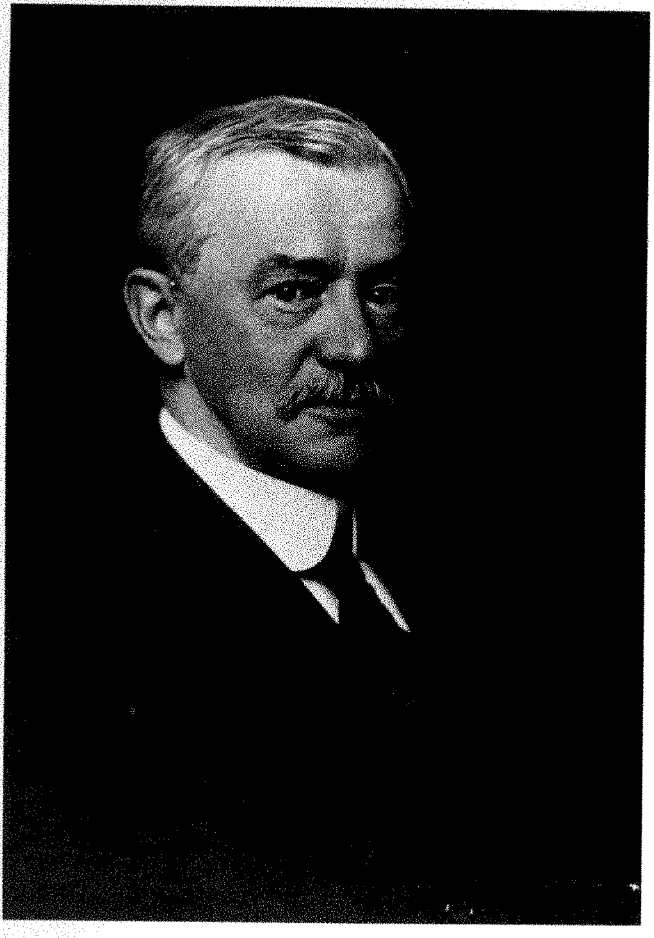

FIG. 5. Howard A. Kelly, Professor of Gynecology, Johns Hopkins.

of the murderous practice of craniotomy and a more sacred regard for the preservation of life."

There were eight papers on gynecology and thirteen related to general surgery at the 1894 meeting. In 1895 there were 17 presentations, seven of which were on gynecologic subjects.

At the ninth meeting of the Southern Surgical and Gynecological Association in Nashville, in 1896, there were 17 reports on the program, of which three related to gynecology. "Vaginal versus Abdominal Section for Pus in the Pelvis" by William D. Haggard, Jr., provoked extensive discussions by Joseph Johnson, Charles Noble, Howard A. Kelly, L. S. McMurtry, R. B. Maury, and W. E. B. Davis. This was an in-depth review of the use of colpotomy and vaginal hysterectomy for the treatment of severe inflammatory diseases in the pelvis. These approaches had been recommended especially by French surgeons, including Doyen, Segond, Pozzi, and others.

Many of the members were always active discussants. Howard A. Kelly, professor of gynecology at Johns Hopkins, was one of the most active members of this Association, frequently presenting papers and often discussing others.

In 1897, there were 19 presentations, six on gynecology and 13 on general surgery. In 1898 there was a total of 17 reports, six on gynecology and 11 on general surgery.

At the twelfth meeting in 1899, President Joseph Taber Johnson, Professor of Gynecology at Georgetown University, spoke as follows:

> "The union of surgery and gynecology in our Association has done much to bring together the men devoting their lives to these two great departments of medicine, and may possibly do much more in the coming century to wipe out the lines of demarkation which now separate them."

Johnson further stated that the revolutionary operation of the intrepid Kentucky surgeon, Ephraim McDowell, constituted a very pleasant union of marriage of surgery and gynecology. He noted that the Southern part of our country had furnished many noted surgeons and gynecologists to the medical profession.

Johnson continued:

> "The practice of surgery and gynecology brings our membership very near together, and it is not at all impossible as the signs of the times are interpreted, that gynecology, as a separate and separated specialty, may gradually cease to exist as such, and become absorbed into the larger and more general department of surgery."
>
> "It is very difficult to say where the office of the gynecological surgeon leaves off and where that of the general surgeon begins . . . who knows but that in the evolution of events, the general surgeon and the gynecologist may soon lie down together, and a little child may lead them."

By 1900, there were 150 members of the Association, of whom 22 were gynecologists. Of 22 presentations, seven were on gynecologic subjects. At the 1901 meeting, 24 papers were presented and nine were on gynecologic subjects.

At the 28th session, in 1915, Thomas S. Cullen, Professor of Gynecology at the Johns Hopkins School of Medicine, gave a lengthy Presidential Address. He discussed the status of hospitals, the trained nurse, education, art and medicine, the beginning of radiation therapy and the importance of pathology. At this meeting in 1915, he stated:

> "After trying to analyze the secret of the success of this Society, I have come to the conclusion that its method of organization, namely, the divorcing of the scientific from the business sessions, has been an important factor. Then it seems that all of our members who take part in the proceedings aim to save their best work for these gatherings, but the most important of all is the fact that in the selection of the members such great care has been exercised that there is rarely, if ever, a discordant note. This Society is really the clearing house for the year's work, and the stimulus obtained at these meetings is of lasting value. If the Councils in the future select as wisely as they have done in the past, this Association will have an ever increasing sphere of usefulness. . ."

The report of the Council on December 14, 1915, recommended that a Committee of three, consisting of Stuart McGuire, Chairman, J. W. Long, and J. M. T.

Finney "be appointed to report on the best method of rendering the list of members more elastic, to recommend any immediate changes in the Constitution and By-Laws, and to consider the question of dues and suggestions to the Committee from the members."

At the conclusion of the meeting in 1915, Cullen, the recent President of the Association, was elected to the Council, as was the custom. The following year at the 29th annual business meeting of the Association at White Sulphur Springs, West Virginia, on December 13, 1915, the report of the Council included the following:

> "The Council endorses and recommends the following changes in the Constitution and By-Laws of the Southern Surgical and Gynecological Association, this being the report of the special Committee composed of Stuart McGuire, Chairman, John W. Long, and J. M. T. Finney, who were appointed at the previous meeting:
>
> 1. C: Change the title from the Southern Surgical and Gynecological Association to the Southern Surgical Association and change the word 'Member' to 'Fellow' and 'Membership' to 'Fellowship' wherever they occur in the Constitution and By-Laws."

This proposal was accepted by the Association.

It may appear surprising at first that the Committee, named by the Council during the presidency of T. S. Cullen, should recommend omission of "Gynecological" from the name of the Association, since Cullen was such a prominent gynecologist in this country, and was known widely over the world. Perhaps this is explained by understanding Cullen's philosophy. He stated frequently that trainees in gynecologic surgery should be able to care for any surgical disease within the abdominal cavity when found at the time of laparotomy. Secondly, he insisted that the training of gynecologic surgeons and general surgeons should include special training in pathology, both in general pathology and that related to a specialty. The 5 years of training in gynecologic surgery in the Johns Hopkins Hospital under Cullen were interspersed with surgical experiences with the General Surgical Service. In addition, one full year in general pathology was followed by a second year in gynecologic pathology, the latter while assisting in surgical operations. Cullen arranged a continuous relationship with the Department of Pathology throughout the training of each resident. Cullen's predecessor, Howard A. Kelly, had instilled the necessity of training in pathology.

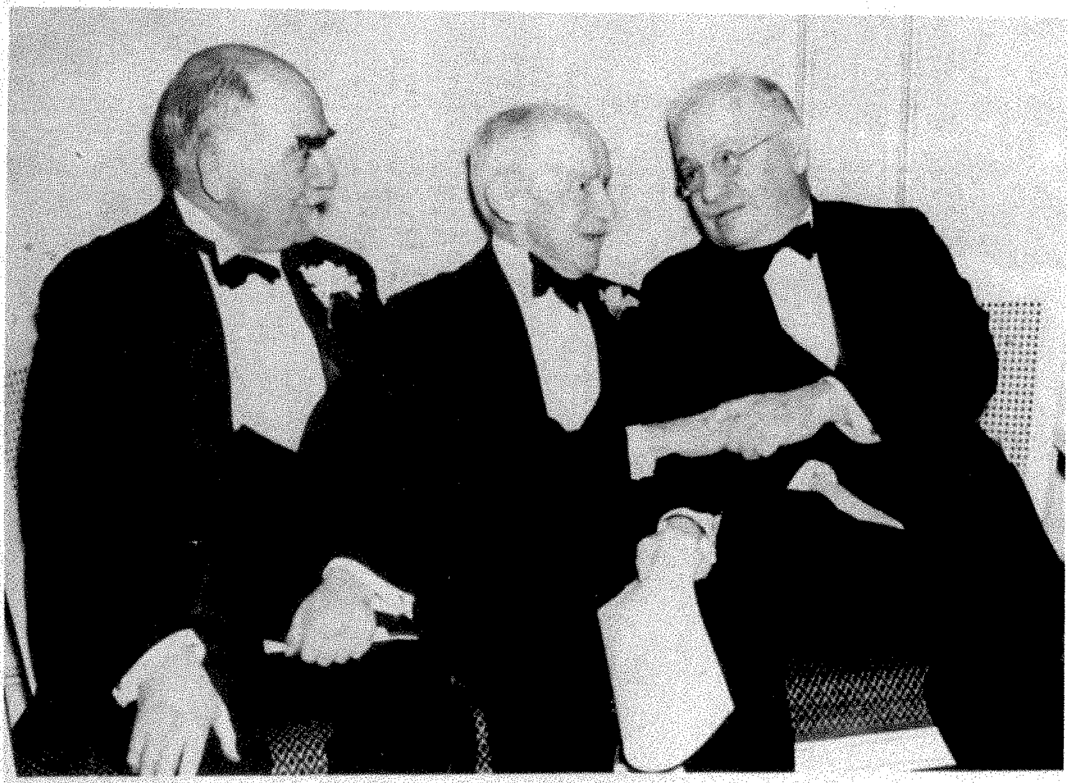
I believe that Cullen's opinions must have been received well by this Committee which recommended change of the name of the Southern Surgical and Gynecological Association to the simpler and more concise form, "The Southern Surgical Association." After the name change, contributions from gynecologists diminished through the years. Was this name change a factor in the decrease in activity of the gynecologists? Likely it was related to increasing technological factors in each specialty and the increasing number of medical organizations.

FIG. 6. Thomas S. Cullen, President 1915, Professor of Gynecology, Johns Hopkins.

When I was his resident, Cullen expressed to me his opinions of the Southern Surgical Association on a number of occasions. He stated that this was the leading surgical association in the world, that the members saved their best work for the annual meetings, that the fellowship was unexceled, and that its influence was important for American surgery. He also indicated that he would be pleased if I were a member some day.

Gynecological presentations numbered three in 1916, four in 1917, seven in 1918, five in 1919, nine in 1920, and five in 1921.

In his presidential address in 1922, C. Jeff Miller, Professor of Gynecology at Tulane, reviewed the scientific advances in surgery during the 20 years preceding the organization of the Southern Surgical and Gynecological Association. Intense efforts had ushered in knowledge of cellular pathology, primary wound healing, fermentation, immunology, and bacteriology. Only 5 years before the origin of this Association, Lister had announced his methods of antisepsis in surgery which



Thomas S. Cullen Howard A. Kelly

FIG. 7. Tom Cullen, Howard A. Kelly, J. M. T. Finney, at Cullen's 70th birthday celebration, 1934. Three Presidents of the Southern Surgical Association: two gynecologists and one surgeon.

led to aseptic surgical techniques (1895). The Pasteur Institute was founded in Paris in 1888, 1 year after the Southern Surgical Association. Miller indicated that hospital standards, surgical indications, and results had improved.

At the 1922 meeting, 38 papers were presented, of which only two were related to gynecology.

In 1927, President Guy L. Hunner of Baltimore summarized his concepts of ureteral stricture and urinary stones. He emphasized the importance of the work of Kelly in female urology. Thirty-seven papers were presented, including only three on gynecology. Thereafter, gynecologic presentations continued to decrease in number (Table 1).

In 1929, President Lucius E. Burch, Professor of Gynecology at Vanderbilt University, made a strong recommendation that residents in gynecologic surgery should have 5 years in training. The first year should be devoted to internal medicine, the second to pathology, and the next 3 years to the operating room, laboratories, and the wards. He did not include obstetrical training in his recommendations for the training of a gynecologist. In 1929, six of 35 presentations related to gynecology.

At the 1954 meeting, President John C. Burch, son of Lucius Burch and Professor of Gynecology at Vanderbilt University, advised that strict standards of pelvic surgery include . . . "the conservation of useful function." He indicated that improvement in surgical training programs was needed.

At the 1980 meeting, President Laman A. Gray, Sr. of Louisville recommended that the pelvic surgeon or gynecologist have additional training in general surgery, to include intestinal surgery, urologic surgery, hepatobiliary, and intra-abdominal vascular surgery.

Evolution

The American Gynecological Society (founded in 1876), consisting of both gynecologists and obstetricians, was the most influential voice in its field until the past two or three decades. Their meetings were impressive. Amalgamation with the American Association of Obstetricians and Gynecologists diluted its prestige and the luster of its early years has faded.

The formation of the Society of Pelvic Surgeons in 1952 by Joe V. Meigs, of Boston, member of the Southern Surgical Association, has had a stimulating influence on surgical gynecology. Its 150 members, mostly from this country, but with representatives from many countries, have placed much emphasis on the advancement of surgical techniques in gynecology, urology, and general surgery in the pelvis. In recent years, the American College of Surgeons and the American College of

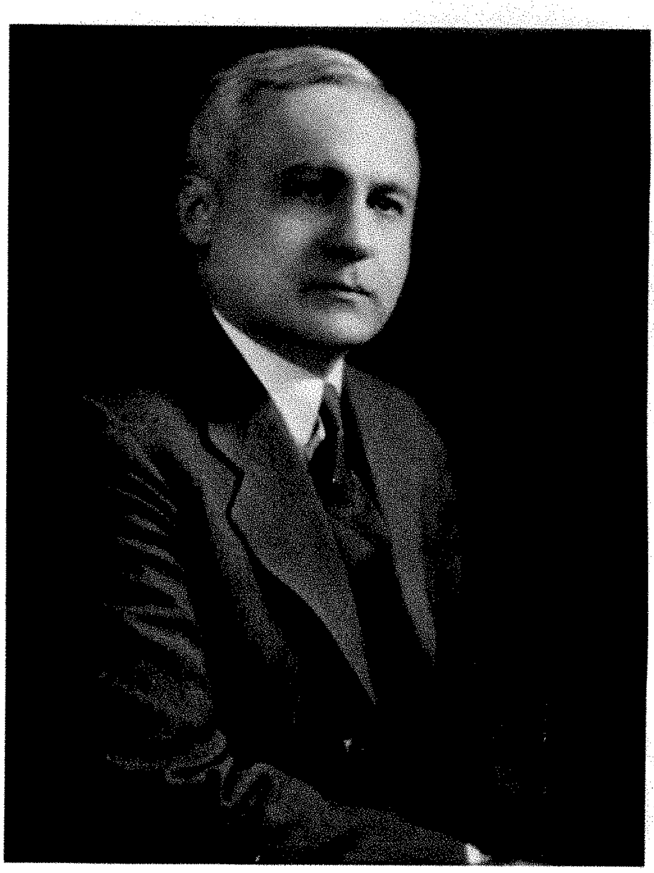

FIG. 11. Emil Novak, Professor of Gynecology, Johns Hopkins: one of the prolific contributors.

have stimulated post-residency surgical training programs. This has improved the quality of pelvic surgery.

In the early years of the Association, the number of presentations devoted to gynecologic topics varied from 57 to 11%, averaging 23% of the total. This has decreased to 1 or 2% in recent years (Table 1). Probably the principle reasons for the decrease in the number is that fewer gynecologic surgeons have been elected to membership in the Southern Surgical Association over the past 30 years. Over that period more than a dozen distinguished gynecologist members have died. These include Joe V. Meigs, Langdon Parsons, Lucius Burch, John Burch, Curtis Tyrone, Glenn Craig, Walter Holmes, J. M. Hundley, Jr., Emil Novak, W. T. Black, Lawrence Wharton, E. H. Richardson, Frank Whitaker, and others. Also, in the past 20 years, only one gynecologic surgeon has been admitted to membership. In the first 50 years, ten presidents were gynecologists. In the second 50 years, only two were gynecologists.

Developments in cardiovascular surgery have stimulated the admission of many of those able specialists who have presented frequent dramatic reports. It is evident that many subspecialties have become so highly specialized that the gynecologic surgeon cannot find any application in his own field. Abdominal surgery and gynecologic surgery should have a closer relationship than any other subspecialties.

The importance of the inclusion of general surgical training in the education of the gynecologic surgeon and the pelvic surgeon is being accepted increasingly in training programs. The general surgeon, certainly the abdominal surgeon, likewise will benefit from exposure to gynecologic surgery. The relationship should be nurtured.

Gynecologists have had a strong commitment to the Southern Surgical Association since its founding. It is to be hoped that they will have the opportunity and find the stimulus to continue their contributions through the next century.

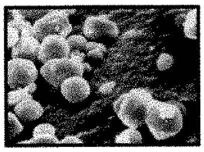
FIVE REASONS WHY YOU SHOULD BE USING A POWDER-FREE GLOVE

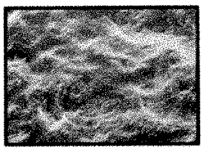
Surgical gloves. You might not give them much thought, but you should. Because the wrong glove can lead to serious post-operative complications.

That's why PRISTINE™ is the right surgical glove. This new powder-free glove represents a remarkable breakthrough for surgeons. The reason? Actually, there are five reasons.

1. Prevent the risk of post-operative Granulomatous reactions. Unlike powdered gloves, PRISTINE powder-free surgical gloves have no starches, talcs or powders of any kind. So we eliminate particulate-related post-op problems such as peritonitis, adhesions, uveitis, or tissue trauma.



Powdered glove magnified 1000X



PRISTINE powder-free gloves

PRISTINE gloves also eliminate dermatitis problems for surgeons. Our gloves are hypoallergenic. So we prevent the skin irritation commonly associated with glove powders.

2. Save Time. Our powder-free composition gives you another important advantage: time. Use a pair of PRISTINEs and you'll never have to go through another pre-operative "glove scrub" again. Instead, you can be doing something more important. Performing surgery.

3. Save Money. PRISTINE powder-free gloves save you more than just time. We save you money. Because once you put on a pair, you can dispose of all the sterile glove wipes and basins you are currently using.

4. Benefit from enhanced tactile sensitivity. Our pure latex construction offers you another advantage: a non-slip grip and the sure-handed control you need for handling the most delicate instruments. Which means PRISTINE gloves are especially well-suited for plastic surgery, neurosurgery, and microsurgery.

5. Get a free pair of PRISTINE powder-free gloves. The truth is, there are plenty of reasons why you should choose PRISTINE. That's why we're making this special offer. Send us a card in the mail and we'll send you a free pair of our gloves the day we receive it. Just like we do with all our orders.

So contact World Medical Supply today. You'll never wear a powdered glove again.

PRISTINE. The Surgeon's Glove.

Brief Summary: Please see package insert for full prescribing information.
INDICATIONS AND USAGE: Topical corticosteroids are indicated for the relief of the inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses.
CONTRAINDICATIONS: Topical corticosteroids are contraindicated in those patients with a history of hypersensitivity to any of the components of the preparation.
PRECAUTIONS: ***General:*** Systemic absorption of topical corticosteroids has produced reversible hypothalamic-pituitary-adrenal (HPA) axis suppression, manifestations of Cushing's syndrome, hyperglycemia and glucosuria in some patients. Conditions which augment systemic absorption include the applications of the more potent steroids, use over large surface areas, prolonged use and the addition of occlusive dressings. Therefore, patients receiving a large dose of a potent topical steroid applied to a large surface area and under an occlusive dressing should be evaluated periodically for evidence of HPA axis suppression by using the urinary free cortisol and ACTH stimulation tests. If HPA axis suppression is noted, an attempt should be made to withdraw the drug, to reduce the frequency of application, or to substitute a less potent steroid. Recovery of HPA axis function is generally prompt and complete upon discontinuation of the drug. Infrequently, signs and symptoms of steroid withdrawal may occur, requiring supplemental systemic corticosteroids. Children may absorb proportionally larger amounts of topical corticosteroids and thus be more susceptible to systemic toxicity. (See PRECAUTIONS—Pediatric Use.) If irritation develops, topical corticosteroids should be discontinued and appropriate therapy instituted. In the presence of dermatological infections, the use of an appropriate antifungal or antibacterial agent should be instituted. If a favorable response does not occur promptly, the corticosteroid should be discontinued until the infection has been adequately controlled.
Information for the Patient: Patients using topical corticosteroids should receive the following information and instructions: 1. This medication is to be used as directed by the physician. It is for external use only. Avoid contact with the eyes. 2. Patients should be advised not to use this medication for any disorder other than for which it has been prescribed. 3. The treated skin area should not be bandaged or otherwise covered or wrapped as to be occlusive unless directed by the physician. 4. Patients should report any signs of local adverse reactions especially under occlusive dressing. 5. Parents of pediatric patients should be advised not to use tight-fitting diapers or plastic pants on a child being treated in the diaper area, as these garments may constitute occlusive dressings.
Laboratory Test: The following test may be helpful in evaluating the HPA axis suppression: ACTH stimulation test
Carcinogenesis, Mutagenesis and Impairment of Fertility: Long-term animal studies have not been performed to evaluate the carcinogenic potential or the effect on fertility of topical corticosteroids. Studies to determine mutagenicity with prednisolone and hydrocortisone have revealed negative results.
Pregnancy Category C: Corticosteroids are generally teratogenic in laboratory animals when administered systemically at relatively low dosage levels. The more potent corticosteroids have been shown to be teratogenic after dermal application in laboratory animals. There are no adequate and well-controlled studies in pregnant women of teratogenic effects from topically applied corticosteroids. Therefore, topical corticosteroids should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus. Drugs of this class should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.
Nursing Mothers: It is not known whether topical administration of corticosteroids could result in sufficient systemic absorption to produce detectable quantities in breast milk. Systemically administered corticosteroids are secreted into breast milk in quantities NOT likely to have a deleterious effect on the infant. Nevertheless, caution should be exercised when any topical corticosteroids are administered to a nursing woman.
Pediatric Use: Pediatric patients may demonstrate greater susceptibility to topical corticosteroid-induced HPA axis suppression and Cushing's syndrome than mature patients because of a larger skin surface area to body weight ratio. Hypothalamic-pituitary-adrenal (HPA) axis suppression, Cushing's syndrome and intracranial hypertension have been reported in children receiving topical corticosteroids. Manifestations of adrenal suppression in children include linear growth retardation, delayed weight gain, low plasma cortisol levels, and absence of response to ACTH stimulation. Manifestations of intracranial hypertension include bulging fontanelles, headaches and bilateral papilledema. Administration of topical corticosteroids to children should be limited to the least amount compatible with an effective therapeutic regimen. Chronic corticosteroid therapy may interfere with the growth and development of children.
ADVERSE REACTIONS: The following local adverse reactions are reported infrequently with topical corticosteroids, but may occur more frequently with the use of occlusive dressings. These reactions are listed in an approximately decreasing order of occurrence: burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, hypopigmentation, perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, miliaria.
OVERDOSAGE: Topically applied corticosteroids can be absorbed in sufficient amounts to produce systemic effects. (See PRECAUTIONS.)
DOSAGE AND ADMINISTRATION: Topical corticosteroids are generally applied to the affected area as a thin film three or four times daily depending on the severity of the condition. Occlusive dressings may be used for the management of psoriasis or recalcitrant conditions. If an infection develops, the use of occlusive dressings should be discontinued and appropriate antimicrobial therapy instituted.
HOW SUPPLIED: 1 oz. tube with rectal applicator.
CAUTION: Federal law prohibits dispensing without prescription.

WE HAVE ONLY GOOD THINGS TO SAY ABOUT CANCER OF THE COLON.

If detected early, the cure rate for colorectal cancer is very high.

It can be as high as 75%.

Because we now know how to detect it early. And we know how to fight it once we detect it.

There are three simple checkup guidelines for men and women without symptoms.

One, get a digital exam every year. This is recommended for everyone over 40.

Two, get a stool blood test every year if you are over 50.

Three, after two initial negative tests one year apart, get a procto exam every three to five years if you are over 50.

These guidelines are the best protection against colorectal cancer you can have.

If you're not over 50, please give this information to friends and loved ones who are.

In any case, please help spread the word.

Good news doesn't always travel fast.

AMERICAN CANCER SOCIETY®

Get a checkup. Life is worth it.

Honorary Fellows of the First Century

ISIDORE COHN, JR., M.D.

From the Department of Surgery, Louisiana State University School of Medicine, New Orleans, Louisiana

HONORARY MEMBERS are mentioned in the first meeting, Volume 1 of the Transactions of the Association for the Birmingham, Alabama meeting of December 1888. Unfortunately, the comment is a negative one, since Article XV of the By-Laws reads: "By-Laws Article XV. No Honorary Member shall be placed upon the roll of this Association." The very fact of this inclusion in the original By-Laws indicates there must have been some discussion about the possibility of Honorary Membership from the beginning of the Association.

Throughout the *Transactions* there is considerable confusion regarding the status of Honorary Members, their qualifications, their numbers, and the status of the Constitution and By-Laws with regard to them. For many of the Honorary Members elected from overseas, there is no indication that they ever attended any meeting, that they sent letters regretting their inability to attend, or even any indication that they accepted the Honorary Membership that had been conferred on them. Some of the confusing situations probably are related to the changing status of the organization, the change in location of the secretarial office, and the inertia that accompanies any organization with respect to the printed word which is its bible.

Volume II, 1889, has a listing of members and identification of those who are "Founders," but the status of Honorary Membership is unchanged.

Volume III, 1890, lists Members, "Founders," and lists the year that Members were elected, but there have been some changes in the By-Laws. Two By-Laws have been deleted and the article prohibiting Honorary Members is now Article XIII, but the wording is unchanged.

Volume VI for 1893 includes a note in the minutes for Thursday, November 16, 1893, which reads as follows: "It was moved to revoke By-Law XIII, and to provide for Honorary Members in foreign countries limited to ten. (To lie over one year)."

By the meeting of 1894, recorded in Volume VII, it is clear there has been a change in the sentiment of the members as the Report of the Council given on Thursday, November 19, 1894, includes the following: "A resolution was passed to recommend to the Association the adoption of the resolution offered at the last meeting to elect the number of Honorary Members to the number of ten, placing the limit at that number, beginning with the election of five at this session. Viz: S. Pozzi, of Paris; A. Martin, of Berlin; George Foy, of Dublin; Charles Jacobs, of Brussels; and O. Morisani, of Naples." None of these are listed in the roster of Members and there is no separate listing of Honorary Members nor is there any indication that any of these five attended the meeting. As a matter of fact, as one reviews the list of Members and guests attending the meetings, no overseas Honorary Member ever attended any of the meetings until 1978.

Volume VIII, 1895, lists alphabetically on a separate page preceeding the usual roll of Members, the five Honorary Members elected in the previous year. It is of interest that the Honorary Members are identified only by name and city of origin without any of the information regarding their academic or other activities as is the case for Members. Furthermore, there is no indication in this or the preceeding volume regarding how these

---

Presented at the 100th Anniversary Meeting of The Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests: Isidore Cohn, Jr., M.D., Department of Surgery, Louisiana State University School of Medicine, 1542 Tulane Avenue, New Orleans, LA 70112.

Submitted for publication: December 22, 1987.

five individuals were selected, who proposed them, or what their contributions were to the Association or to surgery in general. This style of listing the Honorary Members is continued until Volume XLI where the last name is that of the most recently elected Honorary Member, but others are still in alphabetical order. From this point on, names that are added are placed in chronological order, but those listed through 1917 remain in their alphabetical sequence. Volume XLVIII, 1935, places everyone in alphabetical order. Volume LX, 1948, is part chronologically and part alphabetically arranged. Volume LXV, 1953, is arranged completely in chronological order. Volume LXXXII, 1970, has everyone in alphabetical order and this sequence is continued until the present time.

It is of interest that Volume VII, which contains the minutes regarding the election of the Honorary Members and also a separate roster listing them, did not delete the article in the By-Laws, which prohibited their membership. Volume VIII eliminates Article XIII and also includes a change in the Constitution, which was not recorded in the previous year. Section 2, Article IV of the Constitution reads as follows: "The Honorary Member shall not exceed 10 in number, and shall enjoy all the privileges of other Members, excepting to vote or hold office, but shall not be required to pay any fee."

There is no change in the status of Honorary Members, their listing, the Constitution, By-Laws, or anything else related to Honorary Membership until Volume XV where the Report of the Council for November 13, 1902 includes the following: "As Honorary Members, the Council nominates: Dr. Thaddeus A. Reamy, of Cincinnati, Dr. J. McFadden Gaston, of Atlanta, and Dr. Richard B. Maury, of Memphis, Tennessee."

It is interesting to note that all three of these are from the United States, whereas the original intention had been to elect up to a maximum of 10 foreign members. At least two of the newly elected Honorary Members had been Members of the Southern before this time but there is no listing of Dr. Maury in the membership and, once again, the Honorary Members are listed before the Members with no additional identification. Dr. Gaston continues to be listed in the regular membership file, in addition to being listed as an Honorary Member, whereas Dr. Reamy is listed only as an Honorary Member and not under the regular membership listing. There is nothing in the minutes to indicate when the decision was made to allow the election to Honorary Membership of either individuals practicing in the United States or of individuals who had prior membership in the Southern.

In Volume XVI, 1903, there is the first notice of the death of an Honorary Member. Dr. J. McFadden Gaston is one of the Members of the Southern who had been elevated to Honorary Membership and his death is recorded also in the membership list where his name is still present. There is a three-page signed memorial preceeded by a full-page picture.

The next addition to the list of Honorary Members is recorded in Volume XX, 1907, where Dr. L. M. Tiffany of Baltimore appears as an Honorary Member. In the Transactions for the previous year, Dr. Tiffany is listed as a Member but in this volume his listing is only under the group of Honorary Members without any further identification. This is particularly surprising since the list of officers on the preceeding page indicates he was President in 1895.

In the Report of Council for December 19, 1907, item 2 reads, "The Council recommends that in Section 2 of Article IV of the Constitution, in reference to Honorary Members, that the word 'twenty-five' be substituted for 'ten' and that Dr. L. McLane Tiffany, of Baltimore, be made an Honorary Member."

Despite the Report of Council referred to for 1907, Volume XXI for 1908 shows no change in Article IV of the Constitution regarding the number of Honorary Members and there is no note in the minutes to indicate there was any discussion of the change. No additional Honorary Members have been added; however, the death of a second Honorary Member is recorded, Dr. Thaddeus A. Reamy, of Cincinnati. The memorial to him, in Volume XXII for 1909, includes the following unusual sentence, "In 1890 he joined the Southern Surgical and Gynecological Society and in 1902 was made, by request, an Honorary Member."

Volume XXIII for 1910 continues to list Dr. Thaddeus Reamy under the Honorary Members, indicating he is deceased, even though the other Honorary Member who had died was listed only once. This is more unusual in view of the fact that the memorial notice on Dr. Reamy had appeared in the previous Transactions.

The Report of Council given on December 15, 1910 includes the following: "5. That the following names are proposed for Honorary Membership: Sir Thomas Myles, of Dublin; Mr. Mayo Robson, of London; Mr. Arbuthnot Lane, of London; Mr. B.G.A. Moynihan, of Leeds; Mr. Robert Jones, of Liverpool; Mr. H.J. Stiles, of Edinburgh, Mr. Rutherford Morrison, of New-Castle-on-Tyne." (See comments on Vol. LIX, 1947.)

Despite this election of seven new members, the Constitution still reads that the number of Honorary Members "shall not exceed ten."

In an attempt to explain the election of the large number of British surgeons, it occurred to me that there might be some record in the Royal College of Surgeons of England which might explain a traveling group that participated in the meeting of the Southern Surgical Association and were elected to Honorary Fellowship as a token of the appreciation of the Members for their visit. Mr. I. F. Lyle, Librarian, the Royal College of Surgeons of England, responded to my inquiries with interesting information but, unfortunately, this does not provide the answer for which I was searching. However, his letter is of sufficient interest, that it seems worthy of recording.

> "I have done some checking and as far as I can discover this (the meeting in December, 1910) was not an official College visit. Two of the names on your list, Sir Thomas Myles and H.J. Stiles were not Fellows of this College, but of the Irish and Edinburgh Colleges respectively, and there is no evidence to support a visit of this nature in the official records. I have also consulted a number of biographical sources in the hope of finding some mention of a visit in 1910 but here again I have drawn a complete blank. I cannot find that Moynihan visited the United States between his 1903 and 1917 visits while Arbuthnot Lane attended an international congress there in 1911, but not in 1909 or 1910. If any evidence of a visit existed I find it hard to believe that various biographers would not have mentioned it, particularly as the party apparently consisted of so many eminent and fast rising surgeons.
>
> A surgical travelling club, as you suggested in your letter, might have been the reason for these men to have been together. However I can only find the existence of two in Britain at that time, that which was founded by Berkeley Moynihan in July 1909 and which became the Moynihan Chirurgical Club in 1929. His initial invitation was to provincial surgeons of whom, apart from Moynihan himself only three, Robert Jones, Stiles and Rutherford Morison appear on your list. Furthermore, the first foreign meeting of the club was known to have taken place in Paris in 1911. The other club, 'The Surgical Club' was founded in 1910 and the first members were London, as opposed provincial, surgeons.
>
> All this strengthens my opinion that the names you have given me were not present at the Nashville meeting in December 1910, in fact, I think it unlikely they were collectively even in the United States at the time. However, I may be able to offer a solution. In his book *The life of Sir Robert Jones,* London, 1934, Frederick Watson wrote: 'Sir Harold Stiles, in July 1910, writing from Edinburgh (to Jones), where the American surgeons had been on a visit, after giving an account of their doings, in which he himself had taken a busy part, concludes. . . .' I wonder whether it was a party of American surgeons who visited Britain in 1910 and upon their return, those who were members of the Southern Surgical Association decided to honour their hosts by making them honorary members. It is only a theory but it seems to fit the facts and certainly at that time there seems to have been more American surgeons visiting Britain than British surgeons visiting the United States."

The first item on the Report of Council for December 14, 1911 reads: "1. Dr. Ferdinand Herff, of San Antonio, Texas, one of the Founders of the Association, one of the most prominent and able surgeons of his native State, and now at the advanced age of 91, be transferred from the roster of the Fellows to Honorary Membership." The list of Honorary Members includes 15 people, even though Article IV of the Constitution still reads the number shall not exceed ten.

In Volume XXV, 1912, Article IV of the Constitution has been changed and Section 2 reads as follows: "The Honorary Member shall not exceed 25 in number and shall enjoy all the privileges of other Members, excepting to vote or hold office, but shall not be required to pay any fee."

An addition to the role of Honorary Members is recorded in Volume XXVII for 1914 where item 4 of the Report of the Council for December 17, 1914 reads: "that Dr. Joseph Taber Johnson and Dr. Nicholas Schilling be transferred to Honorary Membership." Both of these men were members of the Association before they were made Honorary Members, Dr. Schilling having been a Founder Member and Dr. Johnson having been elected in 1889 and having served as Vice-President in 1896 and as President in 1899.

Volume XXIX for 1916 includes some significant changes in the Constitution and By-Laws as proposed by the special committee appointed to review these items. "Members" became "Fellows" throughout, including the designation of Honorary Fellows. Report of Council for December 13, 1916 includes the following item 3:

> "Article IV—The Honorary Fellows of the Association shall not exceed 25 in number. They shall be nominated by the Council and elected by the Association. They will not be required to pay any dues and shall enjoy the privileges of other members except that of voting or holding office. This exception does not apply to Founders."
>
> "7. The Council further recommends that the 7 surviving Founders of the Association be transferred to the list of Honorary Fellows. They are: Dr. R. N. Cunningham, of Birmingham, Alabama; Dr. J. D. S. Davis, Birmingham, Alabama; Dr. J. A. Goggans, Alexander City, Alabama; Dr. George Ben Johnston, Richmond, Virginia; Dr. John W. Long, Greensboro, North Carolina; Dr. I. S. Stone, Washington, D.C.; Dr. Hugh M. Taylor, Richmond, Virginia."

The following sentence appears at the end of the Report of the Council: "The Report of the Council was considered, section by section, as read, and on several motions, duly seconded and carried, was adopted." This suggests that the earlier rule to hold things over for 1 year was disregarded and that all of these changes were accepted. However, the change does not appear in the Constitution at the beginning of this volume of the *Transactions.*

The *Transactions* do record the death of Dr. L. M. Tiffany, who became an Honorary Member in 1907, but the memorial for him does not appear until the next year and is not signed.

In this volume, there is for the first and only time a separate listing of "Honorary Members" including all those so named before this date, and on the next page a listing of the newly designated "Honorary Fellows." After this year, the two lists are merged into one.

The change in Article IV of the Constitution as included in the Report of Council for the previous year is now part of the Constitution in Volume XXX for 1917.

In this volume, the list of Honorary Fellows includes the 7 Founder Members as provided for in the previous year's decision, but includes additional names beyond that. In the discussion of the recommendations for a change in the Constitution, Dr. John Wesley Long suggested that it would be a mistake to prevent individuals from voting or holding office if they had been members of the Southern and were now promoted to Honorary Fellowship. The President suggested that the rule could be overcome by excepting not only Founders, but those who had been active as Members in the last 2 years. Dr. Long made such a motion, which was seconded, and this was voted and carried. Despite the long discussion that is recorded, I do not find this altered wording in the Constitution in the *Transactions* for at least the next 3 or 4 years.

The list of Honorary Fellows has been moved and now immediately preceeds the list of Fellows. Fellows are now listed both alphabetically and geographically. The geographic list has no place for overseas members and those Honorary Fellows who were active members are no longer listed in the geographic section. Dr. William M. Polk of New York is listed as an Honorary Member who died, but including him there are now 25 names listed as "Honorary Fellows."

The confusion about Honorary Fellows continues to be apparent. Volume XXXI for 1918 no longer lists Dr. Ferdinand Herff but there is no indication that he died and there is no memoir on him. Dr. William Polk, whose death was reported the previous year, is so listed again in the Report of Council for December 19, 1918, and there is a memorial to him at the end of the volume. The name of Dr. Hugh M. Taylor is now listed under Honorary Fellows as a Founder.

In 1919, Volume XXXII, there is for the first time a specific listing of Honorary Members who attended the meeting. In addition, the Report of Council on December 18, 1919, comments: "There have been 106 regular Fellows present, in addition, and with much delight, we note the presence of 5 Honorary, but very active Fellows. Viz: Drs. J. W. Long, Louis F. McMurtre, E. S. Lewis, John S. Davis, and Isaac S. Stone. . . ." There are other changes in the status of Honorary Fellows since there is a note under Honorary Fellows of the death of Drs. James A. Goggans, S. Pozzi of Paris, and Nicholas Schilling of Texas. At the end of the *Transactions,* there is a memorial for Dr. Goggans but nothing on either Drs. Pozzi or Schilling, nor are memorials for either of these found in the subsequent volumes.

Volume XXXIII for 1920 continues the listing of Honorary Fellows, takes note of the death of Dr. Russell M. Cunningham, a Founder, and Dr. Joseph Tabor Johnson, plus recording a new Honorary Fellow, Dr. Albert Vander Veer of Albany, New York, bringing the total to 22 Honorary Fellows. The Report of Council makes specific note of the death of Dr. J. A. Goggans, even though this had been recorded in the *Transactions* for the previous year.

The listing of two Honorary Fellows who attended the meeting is continued in Volume XXXIV for 1921. The overall listing of Honorary Fellows notes the death of Dr. Hugh M. Taylor of Richmond, Virginia but does not record two deaths that are mentioned in the Report of Council, that of Dr. R. M. Cunningham of Ensley, Alabama and Dr. Joseph Tabor Johnson of Cherrydale, Virginia. The *Transactions* for the previous year had indicated the death of these two individuals and there is a memoir in this volume for Dr. Johnson but not for the others.

With the establishment of the category of Senior Fellows, as recorded in Volume XXXV for 1922, there now appears between the lists of Honorary Fellows and regular Members, a separate listing of Senior Fellows. The list of Senior Fellows does not include the names of those who are Honorary Fellows nor does it list other Founder Members. Article IV of the Constitution now contains the same wording regarding Honorary Fellows but has a second paragraph dealing with Senior Fellows. The list of Honorary Fellows does not include Dr. R. B. Maury or Dr. Herman Tuholske, though the Report of Council indicates both of them had died as had Dr. Hugh M. Taylor and there are memorials to all three of these in this volume of the *Transactions.*

The death of Dr. Louis S. McMurtre of Louisville, Kentucky, is recorded in Volume XXXVII for 1924, which also includes a memorial to him.

Volume XXXIX for 1926 continues to list Dr. John Wesley Long under the category of Honorary Fellows. However, Report of Council records his death, there is a memorial to him in the volume, and he is still listed as both an Honorary Fellow and a Founder Member in Volume XL for 1927. The election to Honorary Fellowship of Dr. Rudolph Matas is recorded in Council Report for December 15, 1927.

The name of Dr. O. Morisani of Naples, Italy is dropped from Volume XLI for 1928 but his death is not recorded nor is there a memorial to him. Volume XLIII for 1930 handles Dr. A. Martin of Berlin in the same fashion and one can only assume that this is meant to record his death.

The death of Dr. John D. S. Davis of Birmingham, Alabama is recorded in Volume XLIV, 1931, in the Report of Council, but elsewhere he is listed as a Fellow with no indication of his status as an Honorary Fellow. There is a memorial to him which is the only signed memorial in this particular volume.

The name of Dr. Albert Vander Veer of Albany, New York, has been dropped from the list of Honorary Fellows but his death is not noted in the minutes for either 1930 or 1931 and there is no memorial to him in either of these years.

A new tradition, which seems to have been spontaneous, appeared following the Report of Council for December 10, 1931: "10. The distinguished guest, Dr. William J. Mayo, of Rochester, Minnesota, has been a guiding star and an inspiration to Southern surgeons be elected to Honorary Fellowship." At the close of that session, the President, Dr. Hugh Trout, asked Dr. William Mayo if he would like to make any comments as a newly elected Honorary Fellow. Dr. Mayo's comments cover 4 pages in the minutes, which he introduced as follows: "In looking over the names of the group of distinguished surgeons that have been chosen for Honorary Fellowship, I am reminded of pleasant associations with them, and I am fortunate, indeed, in having memories of all of them." Dr. Mayo was either the first or one of the first individuals who was present at the meeting where he was elected primarily as a Honorary Member without having been a member before that time. It was perhaps this combination of factors that lead to the tradition, which has persisted since, of asking Honorary Members to make some comment.

In 1932, Volume XLV breaks with tradition once again in indicating that two individuals were elected Honorary Members in 1931, Dr. William J. Mayo and Mrs. W. E. B. Davis of Birmingham, Alabama. Mrs. Davis is the only woman ever elected to Honorary Membership, the only non-M.D. ever to hold membership, and there is nothing in the minutes for either this year or the previous year to indicate the action taken electing Mrs. Davis to Honorary Fellowship. Her status as the widow of Dr. W. E. B. Davis would explain this action but it is strange that there is no record of the action in the *Transactions.* This same year, the name of Robert Jones of Liverpool has been deleted from the list of Honorary Members with no other indication of his death.

Honorary fellows are listed in alphabetical order in Volume XLVIII for 1935, previously having been listed chronologically by the date of election to Honorary Fellowship. The list indicates the death of Dr. Isaac S. Stone as the last of the Founder Members in the Honorary Fellowship category but does not include Dr. Ernest Lewis whose death is recorded in the Report of Council for December 12, 1935, along with his honorary fellowship status and for whom there is a signed memorial. It is interesting that the death of Dr. Stone is not mentioned in the Report of Council, until the following year, at which time there is also a signed memorial note on Dr. Stone.

Some interesting changes appear in Volume XLIX for 1936. Two Honorary Fellows are indicated as being present, Mrs. W. E. B. Davis, and this would appear to be her first meeting as an Honorary Fellow, and Dr. Rudolph Matas. Article 7 of the Council Report reads: "Dr. J.M.T. Finney be transferred from Senior Fellowship to Honorary Fellowship," and his name has been added to the list at the front of the volume as an Honorary Member.

The list of Honorary Fellows has deleted the names of Sir B. G. A. Moynihan and of George Foy. Lord Moynihan's death is also recorded in the Report of Council and there is a memorial to him signed by W. J. Mayo, the first such memorial to a foreign Honorary Member. There is no record that Lord Moynihan ever attended a meeting of the Southern Surgical Association and since this was during a period when Honorary Members attending the meeting were so indicated, it seems entirely possible that he never participated in any of the activities of the Association.

The death of Sir Thomas Myles is recorded in Volume L for 1937 and there is a signed memorial to him in the *Transactions,* with apparently all memoirs being signed by this time. The list of Honorary Fellows no longer includes Charles Jacobs although there is no other indication of his death and there is no memoir to him.

The death of Honorary Fellow Dr. W. J. Mayo is noted in Volume LII for 1939 in the Report of Council and there is a signed memorial to him. Another death recorded at the same time and also included in the list of memorials is that of Dr. C. H. Mayo. With the elimination of Dr. Mayo from the list of Honorary Fellows, the total list is now down to six.

The number of Honorary Fellows is further reduced in Volume LV, 1943, to four, with the deaths of Drs. J. M. T. Finney and Sir Arbuthnot Lane being noted in the Report of Council and with signed memorials to each.

In Volume LVII, 1945, a new Honorary Fellow is acknowledged following Report of the Council for December 6, 1945: "The fourth recommendation and the Report of the Council is very short but very important; it is that Dr. Alan O. Whipple of New York be elected to Honorary Membership in the Southern Surgical Association." Dr. Whipple, who was present, gave a short response to his election.

In Volume LVIII, 1946, there are for the first time guests from outside the United States: Dr. Jaime De la Guardia from Panama and Dr. Oscar Ivanissevich, from Argentina. Still, there is no record of any Honorary Fellows from overseas being present.

The list of Honorary Fellows for Volume LIX, 1947, includes only one foreign Member, Mr. Rutherford Morrison of Scotland, and his death is indicated in the Report of Council for December 1948. However, of greater interest are the Report of Council for December

11, 1947, where the death of Sir Harold J. Stiles is recorded, and the memoir of him at the end of the *Transactions* signed by Dr. Rudolph Matas. There is a footnote to this memoir, part of which is reproduced here because of its interest to the entire history of honorary members.

> "At a meeting of the Southern Surgical Association (at that time, The Southern Surgical and Gynecological Association), held at Nashville, Tenn., on December 14–17, 1910, the following eminent British Surgeons, who were visiting the United States at that time, were elected to Honorary Membership: Sir Thomas Myles, of Dublin; Mr. Mayo Robson, of London; Mr. (Sir) Arbuthnot Lane, of London; Mr. G.S.A. (Lord) Moynihan, of Leeds; Mr. (Sir) Robert Jones, of Liverpool; Rutherford Morrison, of New-Castle-on-Tyne; Mr. (Sir) Harold J. Stiles, of Edinburgh.
>
> In the course of the 38 years that have intervened since that memorable date, Mr. Harold Stiles (later, Sir Harold) remained the last survivor of that distinguished group until April 19, 1946, when he also passed from this sphere to join the silent majority."

I am unable to tell that any of these Honorary Fellows who were elected from overseas ever attended a meeting. With all now deceased, Sir Harold Stiles' death being recorded this year, and Mr. Rutherford Morrison's being recorded in the following year, it is a strange commentary that none of them had ever been present at a meeting of the Society that elected such a large number to Honorary Fellowship at one time.

In the *Transactions* for 1948, Volume LX, the list of Honorary Fellows includes four names, the newest being Dr. W. Edward Gallie of Ontario, Canada, who was present at the meeting and who made comments after his election. It was noted in introducing him that he was the first Canadian to be elected to Honorary Fellowship.

In the following year, 1949, Volume XLI, another Honorary Member was elected and was also present to make comments following his election. Dr. Evarts Graham of St. Louis, among his early statements, said, "This is the first meeting of this Association that I have attended, although I have read the Transactions and have been told by many of my friends who are Fellows what a wonderful organization it is."

In 1950, Mrs. W. E. B. Davis was the only Honorary Fellow present, and in 1951, Drs. Gallie and Graham were the only two Honorary Fellows at the meeting.

Volume LXV, 1953, no longer includes the name of Mrs. W. E. B. Davis as an Honorary Member, the Report of Council records her death as an Honorary Fellow, and part of the memoir to her reads as follows: "In 1931, Mrs. Davis was unanimously elected an Honorary Fellow of the Southern Surgical Association, the only woman ever to be awarded this distinction." With her death, there was eliminated from the list of Honorary Members all of the original or Founder Members or their representatives, marking a significant turn in the activities of the Association.

The list of Honorary members in Volume LXVIII, 1956, does not include Dr. Evarts A. Graham, and his name is not on the list of people read as having died in the year, but there is a memorial to him in the *Transactions.*

The election of Dr. Howard C. Nafziger, of San Francisco, California, is recorded in Volume LXIX, 1957, and the minutes of the first day of the meeting record the death of the two Honorary Fellows, Drs. Evarts A. Graham and Rudolph Matas, both of whose names have been deleted from the list of Honorary Fellows. It is interesting that this list includes the name of Dr. Nafziger, noting that he was elected in 1958, even though the meeting was in December 1957. This volume contains the signed memoir on Dr. Matas.

The death of Dr. W. Edward Gallie and a memoir to him are recorded in Volume LXXI, 1961.

The election to Honorary Fellowship of Dr. Lester R. Dragstedt, of Gainesville, Florida, is included in the Report of Council for December 8, 1960 in Volume LXXII, which also contains a signed memorial note to Dr. Nafziger.

As noted in *Alice in Wonderland* things get curiouser and curiouser. Volume LXXIII for 1961 lists only Dr. Whipple as an Honorary Fellow, even though Dr. Dragstedt's election was recorded in the previous year. The minutes of the first day of the meeting record the death of Dr. Nafziger, even though the memorial to him had appeared in the *Transactions* of the previous year. The name of Dr. Dragstedt does not appear as an Honorary Fellow until Volume LXXVIII for 1966—6 years after his election.

Dr. Harvey B. Stone of Baltimore was elected an Honorary Fellow following the Report of Council for December 12, 1963, as recorded in Volume LXXV. Dr. Stone is listed as a Fellow with all of his previous titles and is also listed as an Honorary Fellow. Dr. Dragstedt's name does not appear at all. Dr. Whipple is only listed as an Honorary Fellow. The listing of Dr. Stone among the Fellows is the first time that I have been able to find an Honorary Fellow listed along with the regular membership. This year, for the first time, there is a geographic list of members and a list of deceased members, with those who are Founder Members being identified by an "F" but there is no identification accorded to Honorary Members. Dr. Alan O. Whipple is recorded as a deceased Honorary Member and there is a memorial.

Volume LXXVI, for 1964, lists Dr. Harvey Stone as the only Honorary Fellow, which is the lowest number of Honorary Members recorded since they began to be listed separately. In reality this is an error, since Dr. Dragstedt should be listed.

Professor Phillip Sandblom of Lund, Sweden was elected to Honorary Fellowship on December 9, 1970, Volume LXXXII. This volume records three Honorary Fellows, the other two being Drs. Dragstedt and Stone. Neither Dr. Sandblom nor Dr. Dragstedt were listed anywhere among the Fellows but Dr. Stone continues to maintain his listing there, along with his listing as an Honorary Fellow.

In Volume LXXXIV, 1973, the three Honorary Fellows are listed as such and for the first time all three are also included in the full listing of the Fellows. All three are also in the geographic list of Fellows and are identified as Honorary Fellows. Furthermore, there is specific mention that Dr. and Mrs. Dragstedt and Professor and Mrs. Sandblom were all present at the meeting.

In December 1975, the death of Dr. Dragstedt is noted. In Volume LXXXIX, 1977, the death of Dr. Harvey B. Stone is recorded, with memoirs in this volume to both Drs. Dragstedt and Stone, Dr. Sandblom now being the only Honorary Fellow alive.

Dr. Sandblom, the only living Honorary Fellow, attended the meetings in 1978 and 1980.

In 1981, as recorded in Volume XCIII, the Report of Council suggested the Association was taking another rather new and different step in recommending that Honorary Fellowship be conferred posthumously on one of its Members. The explanation given in the meeting was that the nomination of Dr. Alton Ochsner as an Honorary Member had been suggested the year before while he was still alive, with the understanding that it be acted on at the meeting this year. In view of the fact that there had been a consensus to approve this before his death, the decision was made to complete this election. In the same volume is the signed memorial note for Dr. Ochsner.

Two major changes are noted in Volume XCIV for 1982. The election of Dr. John D. Martin, Jr. of Atlanta to Honorary Fellowship is recorded along with his comments following his election. Thus, for 2 years in a row, former Presidents and Members of long standing had been elected to Honorary Membership.

The other important change is that, for the first time, there is a complete listing of the Honorary Fellows. This appears just after the list of meeting places, dates, and presiding officers, and immediately preceeding the list of the Fellows. The Honorary Fellows are listed alphabetically with the date of their election. The only ones listed as being alive are Drs. Martin and Sandblom, both of whose names appear on the facing page above the list of Fellows, where they are listed as Honorary Fellows. Despite this significant change, there continue to be discrepencies in the overall listing of the Honorary Fellows. Dr. Sandblom is listed alphabetically and has his Honorary Fellowship indicated, whereas Dr. Martin's listing among the Fellows does not indicate his Honorary Fellowship. On the other hand, in the geographic listing, both of them have their Honorary Fellowship indicated.

The meetings for 1983 and 1984 were attended by both Drs. Martin and Sandblom, perhaps setting a new record with all the living Honorary Fellows attending these meetings.

In 1985, Volume XCVII, another former President was elected to Honorary Fellowship. In this case, the Honorary Fellow's contributions to the Southern Surgical Association and to surgery in general were pointed out to indicate the significant number of times he and his department had made direct contributions to the meetings of the Association. Dr. H. William Scott, Jr., of Nashville, Tennessee, followed the custom of making comments following his election.

Volume XCVIII for 1986 records another proposed change in the Constitution. An Ammendment was proposed for Article IV, Section I, as follows: "The Honorary Fellows of the Association shall not exceed twenty-five in number. They shall be nominated by the Council and elected by the Association. They will not be required to pay any dues and shall enjoy all the privileges of other Fellows except that of holding office." This change restored the vote to Honorary Fellows, but made no other changes. In accordance with custom, the proposal would be voted on at the next annual meeting and was passed in 1987.

During this meeting another Honorary Fellow was elected, Dr. Warren Cole of Asheville, North Carolina.

At the Centennial Meeting in 1987, another precedent was shattered when Dr. Robert S. Sparkman was elected to Honorary Fellowship at the beginning of the meeting rather than at the end as had been the custom for all previous elections of Regular and Honorary Fellows. This change was decided on at the Council meeting in the previous year, and was meant to recognize the tremendous effort of Dr. Sparkman in planning, organizing, and conducting the special activities of the Centennial Meeting. His comments were a clear indication of his emotions and his gratitude for this honor.

The concept of Honorary Fellowship in the Southern Surgical Association has undergone a number of changes from the original statement that there should be no Honorary Fellows, to a decision that there be a limit of 10 Honorary Fellows and that these come from foreign countries, to including not only Americans but members of the Association in the Honorary category and then increasing the number to 25. In 1912, the restriction to foreign members was formally removed from the Constitution and has not been a matter of concern since then. The exact explanation for the election of a number of foreign members to Honorary status in the relatively early days of the Association is not explained and this policy was essentially discontinued until recently when a new foreign Honorary Fellow was added to the list.

A change in 1916 converted all of the surviving Founders to the list of Honorary Fellows, there being only seven survivors at that time, and each of these continued in the Honorary category until his death. In 1931, another significant change occurred with the election of the only woman as an Honorary Fellow and the only non-M.D. to have ever been accorded Fellowship as well as the only woman to have ever been a member of the Southern in any category.

In the 1940s, there were relatively few Honorary Fellows listed and by the 1960s the number had dropped to an all time low of 1 or 2. From 1975 to 1982, there was only one Honorary Fellow alive, although another precedent was broken during this period when a former Member was elected posthumously to Honorary Fellowship.

The 1980s have seen an increasing interest in the election of individuals to Honorary Fellowship, and all of the recent nominees have been long-standing members of the Southern.

Because precedents have been broken repeatedly in the past, it seems likely that the future history of the Southern Surgical Association will see additional changes in this category and everyone with an interest in the Southern Surgical Association will watch these developments with keen anticipation.

Southern Surgical Association

The Ninety-Seven Presidential Addresses 1888–1987

G. RAINEY WILLIAMS, M.D.

From the Department of Surgery, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma

A LIST OF THE PRESIDENTS of the Southern Surgical Association and the titles of their presidential addresses for the first 100 years of its existence are found in the Appendix. A number of the early addresses were not given titles. These are identified and a one-line description of the subject has been added. Beginning with President Haggard's address in 1888 and through Sawyers' memorable contribution in 1987, there have been 97 published addresses. The three "missing" addresses are explained as follows. In 1904, Floyd McRae was ill and no presidential address was given or published. In 1923, the presidential address by James Mitchell was a slide-illustrated travelogue that was not published. In 1942, the Southern Surgical Association did not meet because of the war. Barney Brooks was President in 1942 and 1943 and gave the presidential address in 1943. There were two other deviations from custom. In 1953, President Bigger was ill and the presidential address was not delivered at the meeting but was published in the *Transactions.* In 1961, President Joseph Donald died before the annual meeting. In accordance with Article VI, Section 2 of the Constitution, Vice President William H. Prioleau of Charleston presided as the President Pro Tem and delivered the presidential address.

With the exceptions just described, the presidential addresses have been delivered at the annual meeting and published in the *Transactions*. Publication in the *Annals of Surgery* was begun in 1936.* The addresses have been given at different points in the program, and the custom of delivering the presidential address at the first morning session of the annual meeting was established in the 1960s. The published addresses have varied greatly in length and should represent what was actually delivered. The presidential address has been an important part of the annual meeting from the beginning and wives have always been encouraged to be in attendance at its delivery. The fact that wives do attend in large numbers continues to be a charming and unique feature of the "Southern Surgical."

Time, space, and reader interest prohibit comments on each of the 97 addresses. Arbitrarily, the addresses are discussed in 20-year segments, selecting several from each segment for individual discussion. The criteria for selection are entirely the author's and will not please every reader. Almost without exception, the addresses reflect careful thought and significant effort. To attempt to furnish an overview, the addresses have been assigned to five subject categories and this is presented in Table 1. Because many of the addresses touch on more than one category, the assignment is arguable. A final caveat is that the addresses have been judged on the basis of their significance by today's standards and it is likely that this assessment would have been different at the time the address was delivered.

1888–1907

The first presidential address by W. D. Haggard, Professor of Obstetrics and Diseases of Women, Medical Department, University of Tennessee, Nashville, was relatively brief. President Haggard began by commenting on the importance of the work of J. Marion Sims and made the interesting statement that had Sims not died, he (Sims) might be delivering the address. Dr.

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests: G. Rainey Williams, Department of Surgery, The University of Oklahoma Health Sciences Center, P.O. Box 26307, Oklahoma City, OK 73126.

Submitted for publication: December 24, 1987.

* Publication of the *Transactions* and of the scientific papers in other journals is discussed elsewhere in this volume.

Haggard elaborated on the hopes for the future of the new organization. Interest in and regard for history and affection for the organization have continued to be hallmarks of the Southern Surgical Association.

The second president, Hunter McGuire of Richmond, was one of the best known surgeons of his time and his acceptance of the presidency was a major factor in the early success of the Southern Surgical and Gynecological Association. His untitled address filled 12 printed pages and began with a defense of the necessity for forming the organization. After admitting that the South lagged behind the North in scientific medical progress, President McGuire eulogized people of the South, including a touching tribute to Confederate surgeons. He concluded with a ringing challenge to the members to continue the high standards and productivity of the traditional southerner.

The third president, George J. Engelmann of St. Louis, Missouri, was elected to membership in the Southern Surgical and Gynecological Association in 1889 and at the same meeting was elected President. His 29-page address (with no illustrations) was entitled "The Health of the American Girl, As Imperilled by the Social Conditions of the Day." The text is an incredibly obtuse argument that women are emotionally different, particularly during adolescence, and its condescending tone would certainly inflame the feminists of the present time. A typical statement (obviously not a sentence) deserves quotation: "The constriction and compression of the corset, the dragging pounds of the skirt, the circulation-impeding garter, the insufficiencies of low-necked dresses, of filmy stockings and thin shoes, and the total absence of protection where it is most needed, the absence of drawers."

The sixth presidential address was delivered at the New Orleans meeting in November 1892, by Bedford Brown of Alexandria, Virginia. Entitled "The Southern Surgical and Gynecological Association—Its Origin, Objects, and Aims," it was a valuable review of the founding, purposes, and early years of the Association. It included a tribute to J. Marion Sims and a clear statement that the organization never intended to be purely sectional but from the start was a national organization. In flowery language, Brown expressed pride in the recovery of the South and the progress of the new organization of surgeons and gynecologists.

George Ben Johnston of Richmond was the tenth president (1897). Johnston announced the subject of his untitled address in the second paragraph as "the prevalence of specialism and who shall be specialists." He further stated "The science of medicine has grown to such gigantic proportions that no one mind can any longer thoroughly master every detail of it; hence the necessity for specialism." While recognizing the desirability of the trained and experienced specialist, Johnston warned against "pseudospecialists" established by false credentials. He called upon the profession to recognize legitimate specialists and to educate the public in this regard. Johnston was a leading surgeon in Richmond and was the subject of the 1947 presidential address.

In 1901, President Manning Simons of Charleston, South Carolina, began his untitled address by noting the deaths during the preceding year of W. D. Haggard and Hunter McGuire, the first and second presidents of the Southern Surgical and Gynecological Association. Simons then stated that the subject of his address was an examination of whether the Southern Surgical and Gynecological Association justified its existence during its first 14 years. Simons concluded that the organization had done so and further suggested an examination similar to that for licensure of individuals who wished to practice specialties, particularly surgery and gynecology.

In 1902, the president was W. E. B. Davis of Birmingham, the single individual most responsible for the founding of the Southern Surgical and Gynecological Association. He was elected secretary at the first meeting and served for 13 years in that capacity. Appropriately, Davis's address, although not given a formal title, dealt with the founding and early years of the organization. His account was more specific and less concerned with attitudes than that of Bedford Brown in 1893. Davis made a number of suggestions regarding the organization that apparently were accepted. The most unusual of these was the suggestion that a sketch of the life of Robert Batty be included in the next volume of the *Transactions*. Batty was a gynecologist from Rome, Georgia, who popularized transvaginal removal of normal ovaries for a variety of complaints. He was not a member of the Southern Surgical and Gynecological Association. Davis was killed in a train-carriage accident shortly after the meeting, and the following year one of the projects he had suggested for the organization was altered to become a tribute to him.

President Howard A. Kelly's address in 1907 was entitled "Art Applied to Medicine and Surgery." This was a scholarly description of the development of medical illustration profusely illustrated by examples of the works being discussed.

1908–1927

In 1911, Rudolph Matas' presidential address was entitled "The Cinematograph as an Aid to Medical Education and Research" with a subtitle "A Lecture Illustrated by Moving Pictures of Ultramicroscopic Life in the Blood and Tissues, and of Surgical Operations." In this long, detailed presentation, Matas described several aspects of the development of motion picture technology including a brief history of the entertainment motion picture industry that was then in an early stage of development. More time was spent in discussing the scientific applications of the techniques. Matas' predictions of future uses were amazingly accurate. At the time, Matas was probably the leading surgeon from the "deep" South and his active participation in and affection for the Southern Surgical and Gynecological Association were important to the organization.

The following year, another internationally known surgical leader, J. M. T. Finney of Baltimore, entitled his presidential address "Surgical Judgment." Finney, educated at Princeton and Harvard, was William Stewart Halsted's "right hand" at Hopkins. He was a highly respected surgeon and a much loved individual. To the current reviewer, the wording of the address seems tortuous. An early paragraph is an illustration—"This is a difficult task which we have set ourselves, because it will be at once apparent that judgment and experience are very closely associated and interdependent, the one upon the other, and that in the consideration of each one separately, and in their several relations, one with the other, there are many different factors to be borne in mind, the relative measure of importance of which it will be found impossible accurately to determine." Finney delivered a strong indictment of American medical education at the time and cited the recently released Flexner Report. He called for public education regarding selection of surgeons and for restricting the performance of operations to those trained as surgeons. Finney's son was to be president in 1959 and, except for a tragic early death, a grandson would have been a strong candidate for the office.

The 1916 address of Thomas S. Cullen, entitled "America's Place in the Surgery of the World," is 35 pages in length with no illustrations and no bibliography. Cullen, a distinguished gynecologist at the Johns Hopkins Hospital and successor to Kelly, covered many aspects of the development of surgery in the United States and summarized its current status. Cullen made the interesting comment "I have seen another surgeon of excellent repute place the handle of his knife in his mouth for safe-keeping while he was busy tying ligatures." In another section of the address, Cullen gave the following advice to surgeons "If you wish to do your maximal amount of good work, you must take at least a two months' vacation each year." This did not include time spent at surgical meetings, which he also recommended.

In 1917, the president of the Southern Surgical Association was William D. Haggard of Nashville. Haggard, son of the first president of the "Southern," was secretary for 16 years beginning in 1901, and his election as president for the year following his term as secretary established a precedent that has not been broken. The title of his address was "The Medical Profession and the Great War." President Haggard lauded the ideals of the Allies—"Our loftiest aims and most sacred ideals have been crystallized and formulated by that great seer, that incomparable patriot and immortal statesman, Woodrow Wilson, Prime Minister of the world." He pointed out that the first American officer to be killed was a physician, Lieutenant Fitzpatrick of the Washington University-based hospital unit, and paid tribute to the Army Medical Corps for its achievements in public sanitation and to William C. Gorgas for his role in the Panama Canal and for his organization of the medical corps for the war. Haggard even cited benefit from the war as follows: "Already this war has emancipated men from the slavery of alcohol, the greatest curse and blight upon humanity."* He also noted great progress in the surgical management of wounds and closed by quoting a poem of Oliver Wendell Holmes, the last stanza of which follows: "Along its front no sabers shine, No blood-red pennons wave, Its banner bears the single line —Our glory is to save."

"Some Tendencies in Contemporary Medicine of Special Interest to Surgeons" was presented by C. Jeff Miller of New Orleans, president in 1922. Miller discussed the state of medical practice and medical organization in the United States and expressed reservations about the burgeoning interest in laboratory medicine. "Sir James McKenzie warned against this when he very correctly said that a hundred new methods of investigating disease in the living increased by just that number the chances for going astray." He mentioned that "socialized medicine is being widely discussed," the first time that phrase appears in a Southern Surgical presidential address.

---

* When this was presented at the Centennial, it was suggested that many present at the meeting seemed pleased that the emancipation was incomplete.

In 1924, LeGrand Guerry of Columbia, South Carolina, delivered the presidential address entitled "Luke, the Greek Physician and Historian." This is one of the most interesting of the presidential addresses. Beginning with a detailed account of what was known of Luke and his life, Guerry traced his accomplishments in chronicling the events of his time. Guerry then shifted to a call for increased religious commitment beginning by stating "Woodrow Wilson, in one of his clearest moments said: 'The sum of the whole matter is this, that our civilization cannot survive materially unless it be redeemed spiritually'."

1928–1947

"No apology needs to be made upon an occasion such as this because of the selection for discussion of a disease which is the most dreaded, most misunderstood, most mismanaged and most mistreated of any disease with which the medical profession has to deal." So began the 1928 presidential address by A. C. Scott of Temple, Texas, entitled "Consistency in the Surgical Treatment of Cancer." After brief comments on the ancient recognition of cancer, Scott put forward clinical observations suggesting that the cause of cancer is a parasite. He recognized that such was not the prevailing opinion of leading pathologists. He further cited evidence that trauma plays a role in the etiology of cancer and that the development of cancer is influenced by immune responses. He presented a realistic but conservative view of the place of surgery in the treatment of cancer and dwelled on the hazards of mechanically spreading cancer cells in operative wounds. He favored the use of the hot cautery in cancer operations. The technique was demonstrated by a motion picture.

President Hugh H. Trout of Roanoke, Virginia, delivered the 1931 address entitled "An Appraisal of the Surgical Treatment of Pulmonary Tuberculosis." The paper is an interesting account of the treatment of pulmonary tuberculosis before any form of chemotherapy, but it is cited because of the bibliography covering only the period 1925 through 1932 and consisting of 1224 published articles! There was even an index of the bibliography. In the text, Trout cited sources of bibliography of the same subject before 1925.

Harvey B. Stone of Baltimore, President in 1936, addressed "Wider Horizons for the Surgeon." This is a well-written discussion of the effects of progress in the physical sciences on such important topics to the surgeon as the cause of cancer. Stone issued a plea that surgeons expand their interests to broader areas in search of relevant new information.

For the fiftieth year of its existence, the Southern Surgical Association met in Birmingham and President Fred W. Rankin's address was entitled "Milestones on the Road of Surgery." After a brief account of the founding and early years of the Southern Surgical Association, Rankin reviewed the important events leading to the development of surgery as a discipline. The subjects ranged from the development of anatomy through the founding of surgical organizations including the American Board of Surgery.

On December 9, 1941, at Pinehurst, North Carolina, Harry Hyland Kerr delivered the presidential address entitled "Once Again." Kerr expressed the opinion that the failure of the United States to join the League of Nations and to provide leadership after World War I were major factors in allowing the rise of militant fascism. Delivered 2 days after the Japanese attack on Pearl Harbor, the text did not mention Japan and identified only Germany as the enemy. The address was obviously prepared when war was imminent and at least the written text was not altered after the attack. Kerr's comments on the magnitude of the neuropsychiatric problems of a drafted army were clearly and unfortunately not heeded.

At the Pinehurst meeting, Barney Brooks, chairman of the Department of Surgery at Vanderbilt University School of Medicine, was elected president. Because of wartime restrictions on travel, no meeting of the Southern Surgical Association was held in 1942, and Brooks became the first and, so far, only individual to be president of the Southern Surgical Association for 2 years. Although the war continued, the 1943 meeting of the Southern Surgical Association was held in New Orleans, and Brooks' presidential address was entitled "Psychosomatic Surgery." Brooks began by commenting that surgery had progressed from anatomic and pathologic emphasis to physiologic emphasis. He used the term "materialistic philosophy" repeatedly and the meaning of this is not clear to the author. He then turned to a consideration of psychiatry and gave his beliefs about the place of psychiatry and its relationship with the field of surgery. He described but did not completely report the results of an ongoing experience of having psychiatrists interview all surgical patients.

In 1944, the Association met in Hot Springs and it seems remarkable that anyone got to the meeting. President Alton Ochsner's address was entitled "Whither Anon" Ochsner pointed out that medical education and particularly postgraduate education had suffered badly during the war and that provisions would be necessary for expanding residencies in the immediate postwar period. Ochsner then considered the future of the practice of medicine. He marshalled evidence that a substantial proportion of the population of the United States did not have access to adequate medical care and that because of readily explainable rising costs, this problem was likely to increase in magnitude. He further suggested that the profession take the lead in fostering some form of national plan for making health care available to all.

Perhaps the most quoted presidential address was that given in 1946 by Daniel C. Elkin of Atlanta. Entitled "The Georgia Blister and Critic," the paper is an account of the activities of H. A. Ramsey, an apparently self-styled physician, whose qualifications included little, if any, education. Beginning in 1854, Ramsey published a monthly journal entitled *The Georgia Blister and Critic.* This consisted principally of scurrilous attacks on the many objects of Ramsey's dislike. Ramsey practiced medicine and campaigned for a faculty position in the new Atlanta Medical School, which was not forthcoming. The final paragraph described Ramsey's arrest on charges of fraud and stated that he absconded and had not been heard of since. In the writer's opinion, it is the most curious of the presidential addresses and one wonders if there was some meaning that time has obscured.*

1948–1967

President Edwin Lehman's address in 1948 was entitled "The Surgical Man." It is a brief, thoughtful, and pleasant discussion of the facets of surgery that attract surgeons and of the facets of personality required by and nurtured in surgeons.

In 1949, the presidential address, entitled "Problems in the Training of the Surgeon," was given by Alfred Blalock, incomparable chairman of the Department of Surgery at the Johns Hopkins University School of Medicine. The address began with reference to a presentation by William Stewart Halsted at Yale University in 1904 describing the residency program at Hopkins. Blalock went on to cite the success of the Halsted system of educating surgeons and then to discuss the threats imposed by the rising cost of medical care and increasingly available health care insurance. Addressing as it did one of Blalock's most intense interests, the paper is a good example of his extraordinary vision.

Deryl Hart of Duke University gave the 1956 presidential address entitled "The Responsibility of the Medical Profession to Medical Education" with the subheading "Contributions of the Geographic Full Time Staff to the Development of the Duke University School of Medicine and Suggestions for the Assumption of More of the Cost of Medical Education by the Medical Profession as a Whole." Hart outlined the development of a unique relationship between the administration of Duke University and the medical faculty. It seems likely that the spirit of harmony, fairness, and justice described in this address was a factor in the emergence of Duke as one of the leading medical institutions of this country.

The shortest printed presidential address of our first century was that of Floyd W. McRae of Atlanta, Georgia, given in 1957 and entitled "As It Was In the Beginning." McRae's father was President in 1904 and did not give the presidential address because of illness.

James D. Rives of New Orleans, President of the Southern Surgical Association in 1958, gave an address entitled "The Impact of the American Board of Surgery Upon Surgical Education in the United States." After briefly reviewing the founding of the American Board of Surgery, Rives gave some perceptive comments about its function and its effects on surgical education. Rives concluded that the American Board of Surgery had become an exceedingly powerful voice in surgical education and that it had, in general, satisfied its aims of elevating the standards of the practice of surgery.

"What the Southern Surgical Association Means to Me" was the title of the 1960 presidential address by Francis M. Massie. Saying "If the conclusion of this address sounds to you flowery and romantic, it is because I am flowery and romantic," Massie, with humor and grace, expressed the affection for the "Southern Surgical" shared by so many members for now 100 years.

In 1962, Robert M. Moore of Philadelphia was President and his address was entitled "The Davis Brothers of Birmingham and the Southern Surgical and Gynecological Association." This is the most complete and concise account of the founding of the Association and its early years before Sawyers' and surely will be referred to many times at the Centennial Celebration. Moore was chairman of the Department of Surgery at the University of Texas Medical Branch in Galveston and became Secretary of the American Board of Surgery.

On the 75th anniversary of the Association, President James A. Kirtley, Jr. of Nashville presented "A Panorama on the Seventy-Fifth Anniversary of the Southern Surgical Association." Kirtley reviewed highlights of the first 75 years including comments on some of the early presidential addresses.

Now an Honorary Member, J. D. Martin's presidential address in 1964 was entitled "The Crossroads of Surgery." Martin traced the changes in the discipline of surgery occurring during the existence of the Southern Surgical Association. He expressed the opinion that increasing government intervention had brought surgery to a crossroads and suggested appropriate directions to consider.

---

* In 1987, the author asked Doctors W. Cole, Laman Gray, Sr., W. Hamm, J. D. Martin, Ed Parker, R. S. Sparkman, and G. Yeager, most of whom heard the 1946 address, to comment on any "hidden meaning." All agreed there was none.

1968–1987

The presidential addresses of the last 20 years were heard at their original presentation by many who will be present at the Centennial. Given, as was true earlier as well, by men who contributed much to the Southern Surgical Association and to American surgery, they are of high quality and continued interest. There is no truly rational way to select some for comment and to appear to ignore others.

In 1971, Edward F. Parker's presidential address was entitled "Metamorphosis in Medicine—For Better or For Worse." This was an examination of some of the problems facing medicine and the changes being considered. Parker questioned the reliability of the data on which a physician shortage was predicted. His discussion of the financing of health care is pertinent today.

In 1973, President James Hardy's presidential address was entitled "She is Risen" and was a provocative discussion of the role of the Southern Surgical Association and its place in the rise of the South.

The 1974 presidential address of David C. Sabiston, Jr. was entitled "Major Contributions to Surgery from the South" and was a characteristically well-composed account of the achievements of McDowell and others up to Blalock. Among the illustrations were several prepared specifically for the address by Mr. Leon Schlossberg. Sabiston acknowledged these as follows: "In these beautiful half-tone illustrations, this distinguished medical artist has made a unique contribution to medical history."

In 1975, President William H. Muller, Jr. traced the development of scientific and specifically surgical societies. This address should be required reading for all surgical residents.

Walter Becker's account of the development of thyroid surgery in 1976 will become a classic reference.

In 1977, H. William Scott, Jr. skillfully drew an analogy between a prerevolutionary armed dispute in North Carolina and the increasing tide of federal regulations affecting surgery in particular.

Robert S. Sparkman, president in 1978, presented a carefully researched and fascinating account of Jane Todd Crawford, the patient of Ephraim McDowell who underwent the first ovariectomy in 1809.

A former secretary and, in 1979, President of the Association, W. Dean Warren discussed the steps in the development of portosystemic shunting. Representing the views of the leading authority on the subject, the paper is of unusual interest.

A detailed history of surgery and surgeons of North Carolina was given by President Felda Hightower in 1980 and certainly qualifies Hightower as a griot.*

Long-respected Laman Gray, president in 1981, discussed the development of the residency program in Gynecology at Hopkins and made recommendations for improved education of those interested in pelvic surgery.

The presidential address in 1982, delivered by the author of this chapter, was a historical review of appendicitis.

Isidore Cohn, Jr., president in 1983, gave a candid and poignant discussion of the challenges and dilemmas faced by chairmen of departments of surgery.

In 1984, President George L. Jordan traced the evolution of medical care from the "unicellular" stage, through many false starts, to the current complex system.

The 1985 presidential address by Robert Zeppa was a timely and sobering look at the cost of graduate medical education and the upcoming problems in providing the necessary funding.

In 1986, President Arlie R. Mansberger, Jr. began with a quote from T. S. Eliot, proceeded to discuss the external forces affecting medical care, and made suggestions for altering medical education to prepare physicians more adequately for the times.

At the Centennial meeting, John Sawyers (from Nashville, as was the first president) reviewed the early history of the organization in a scholarly, comprehensive, and entertaining account entitled "The Origin and Early Development of the Southern Surgical Association."

The presidential addresses of the first 100 years of the Association are, individually and collectively, tributes by its elected leaders to the wonderful organization now known as the Southern Surgical Association. It is hoped that these addresses will continue to be sources of pleasure and stimulation to the membership in the decades and even centuries to come.

---

* A word used by Hightower connoting leadership. It is not included in Webster's Unabridged Dictionary but has been located by computer search of several data bases. Usually it refers to African tribal storytellers or bards.

Appendix
Presidents of the Southern Surgical Association 1888–1987

Year	President	Title of Presidential Address
1888	W. D. Haggard	Untitled—A tribute to Sims and welcome to the members of the new organization.
1889	H. H. McGuire	Untitled—Defends the need for the new organization.
1890	G. J. Englemann	"The Health of the American Girl, As Imperilled by the Social Conditions of the Day"
1891	L. S. McMurtry	"A Plea for Progressive Surgery"
1892	J. McF. Gaston	"Compatibility of Conservative and Aggressive Surgery"
1893	B. Brown	"The Southern Surgical and Gynecological Association—Its Origin, Objects, and Aims"
1894	C. Kollock	Untitled—A brief (five page) review of the contributions of Southern surgeons and gynecologists with emphasis on McDowell.
1895	L. McL. Tiffany	Untitled—An oblique discussion of the duties of physicians to make accurate observations and to share these with others.
1896	E. S. Lewis	Untitled—A discussion of then-current controversies in pelvic surgery.
1897	G. B. Johnston	Untitled—Subject stated in the second paragraph—"the prevalence of specialism and who shall be specialists."
1898	R. Douglas	"Acute General Peritonitis"
1899	J. T. Johnson	Untitled—An overview of the current status of surgery and gynecology.
1900	A. M. Cartledge	"A Plea for the Better Appreciation of the Limitations of our Operative Work"
1901	M. Simons	Untitled—A look at the achievements of Southern medicine and the Southern Surgical and Gynecological Association.
1902	W. E. B. Davis	Untitled—A review of the history of the Southern Surgical and Gynecological Association.
1903	J. W. Bovee	"The Progress of Ureteral Surgery"
1904	F. W. McRae	No address given due to illness of the President.
1905	L. C. Bosher	Untitled—Comments on preparation for a career in surgery.
1906	G. H. Noble	"Surgical Treatment of Puerperal Thrombosis of Pelvic Veins"
1907	H. A. Kelly	"Art Applied to Medicine and Surgery"
1908	F. W. Parham	"Conservative Surgery, Then and Now"
1909	S. McGuire	"Latent and Active Neurasthenia in Its Relation to Surgery"
1910	W. O. Roberts	"Southern Surgeons and Surgery—Before, During, and After the Civil War"
1911	R. Matas	"The Cinematograph as an Aid to Medical Education and Research"
1912	J. M. T. Finney	"Surgical Judgment"
1913	J. Y. Brown	"Diagnosis and Surgical Technique to be Employed in the Handling of Acute Abdominal Conditions"
1914	J. W. Long	"The Wisdom of the Past, A Prophecy of the Future"
1915	B. Saunders	"The Great Professional Problem of the Present Decade"
1916	T. S. Cullen	"America's Place in the Surgery of the World"
1917	W. D. Haggard	"The Medical Profession and the Great War"
1918	I. S. Stone	"The Standardization of Rural Hospitals"
1919	J. E. Thompson	"Surgery and Embryology"
1920	W. Bartlett	"An Estimate of the Value of Local Anesthesia in the Surgery of Today"
1921	R. Winslow	"Retrospect and Prospect"
1922	C. J. Miller	"Some Tendencies in Contemporary Medicine of Special Interest to Surgeons"
1923	J. F. Mitchell	"A Surgical Travelogue" (Slides and moving pictures) Not published.
1924	LeG. Guerry	"Luke, the Greek Physician and Historian"
1925	I. Abell	"A Retrospect of Surgery in Kentucky"
1926	H. A. Royster	"The Influence of Tradition in Surgery"
1927	G. L. Hunner	"Calculus of the Upper Urinary Tract Treated by New Methods; End-Results"
1928	A. C. Scott	"Consistency in the Surgical Treatment of Cancer"
1929	L. E. Burch	"The Surgeon in the Making"
1930	J. M. Mason	"Early Medical Education in the Far South"
1931	H. H. Trout	"An Appraisal of the Surgical Treatment of Pulmonary Tuberculosis"
1932	R. S. Cathcart	"Surgery and Its Relation to Society"
1933	V. P. Blair	"Ruminations of a Journeyman Surgeon"
1934	F. K. Boland	"Progress in Surgery"
1935	R. L. Payne	"The Master Surgeon and the Layman"
1936	H. B. Stone	"Wider Horizons for the Surgeon"
1937	F. W. Rankin	"Milestones on the Road of Surgery"
1938	L. Noland	"The Panama Adventure"
1939	A. O. Singleton	"The Surgeon in the Romantic Story of Texas"
1940	J. S. Davis	"The Story of Plastic Surgery"
1941	H. H. Kerr	"Once Again"
1942	B. Brooks	No meeting because of World War II.
1943	B. Brooks	"Psychosomatic Surgery"
1944	A. Ochsner	"Whither Anon"
1945	C. A. Vance	"The Transylvania Medical Library"
1946	D. C. Elkin	"The Georgia Blister and Critic"
1947	F. S. Johns	". . . He Shall Have a Noble Memory"
1948	e. P. Lehman	"The Surgical Man"
1949	A. Blalock	"Problems in the Training of the Surgeon"

Appendix (*Continued*)

Year	President	Title of Presidential Address
1950	G. V. Brindley	"Surgery Forty Years Ago, Today and Tomorrow"
1951	F. C. Wilson	"Dr. Finney"
1952	I. M. Gage	"Thrombo-Embolic Phenomenon—A Local Process with Regional Spread and Systemic Complications"
1953	I. A. Bigger	"The Education of Surgeons"
1954	J. C. Burch	"What's Wrong with Pelvic Surgery?"
1955	C. Williams	"The Art of Surgery"
1956	D. Hart	"The Responsibility of the Medical Profession to Medical Education"
1957	F. W. McRae	"As It Was In the Beginning"
1958	J. D. Rives	"The Impact of the American Board of Surgery upon Surgical Education in the United States"
1959	G. G. Finney	"Publicity, the Public and the Medical Profession"
1960	F. M. Massie	"What the Southern Surgical Association Means to Me"
1961	J. M. Donald W. H. Prioleau	"Medical School Relationship to its Community: The Case for the Community Hospital"
1962	R. M. Moore	"The Davis Brothers of Birmingham and the Southern Surgical and Gynecological Association"
1963	J. A. Kirtley, Jr.	"A Panorama on the Seventy-Fifth Anniversary of the Southern Surgical Association"
1964	J. D. Martin, Jr.	"The Crossroads of Surgery"
1965	G. W. Horsley	Untitled—A call for re-emphasis on medical ethics.
1966	H. Mahorner	"Impressions"
1967	R. J. Coffey	"The Tempo of Change"
1968	R. J. Noer	"And Gladly Teach"
1969	G. H. Yeager	"Medical Schools of the Southern United States 1779–1830"
1970	H. Wilson	"The Contribution of Surgeons to Basic Science: Implications for Medical Education"
1971	E. F. Parker	"Metamorphosis in Medicine—For Better or for Worse"
1972	G. V. Brindley, Jr.	"The Changing Panorama of Medical Education"
1973	J. D. Hardy	"She is Risen"

How to interpret EKGs in just 8 easy lessons!

The Only EKG Book You'll Ever Need

NEW!

By MALCOLM S. THALER, M.D.

Here it is! The step-by-step "how to" manual that shows you how to interpret EKGs in just 8 easy lessons!

Dr. Thaler gives you a clear, concise, *enjoyable* introduction to EKG interpretation, including the fundamentals of interpretation as well as the advanced technology of pacemakers, excercise testing, and electrophysiologic studies.

An abundance of easy-to-understand illustrations, summaries of important points within each chapter, a cumulative summary at the end of the book, and real-life clinical cases for self-testing all help you learn how to interpret EKGs *quickly and easily.*

8 easy lessons:

1. *The Basics*
2. *Hypertrophy*
3. *Arrhythmias*
4. *Induction Blocks*
5. *Preexcitation Syndromes*
6. *Myocardial Infarction*
7. *Finishing Touches*
8. *Putting it all Together*

279 Pages. 289 Illustrations.
Flexible Binding. 1988. $19.95.

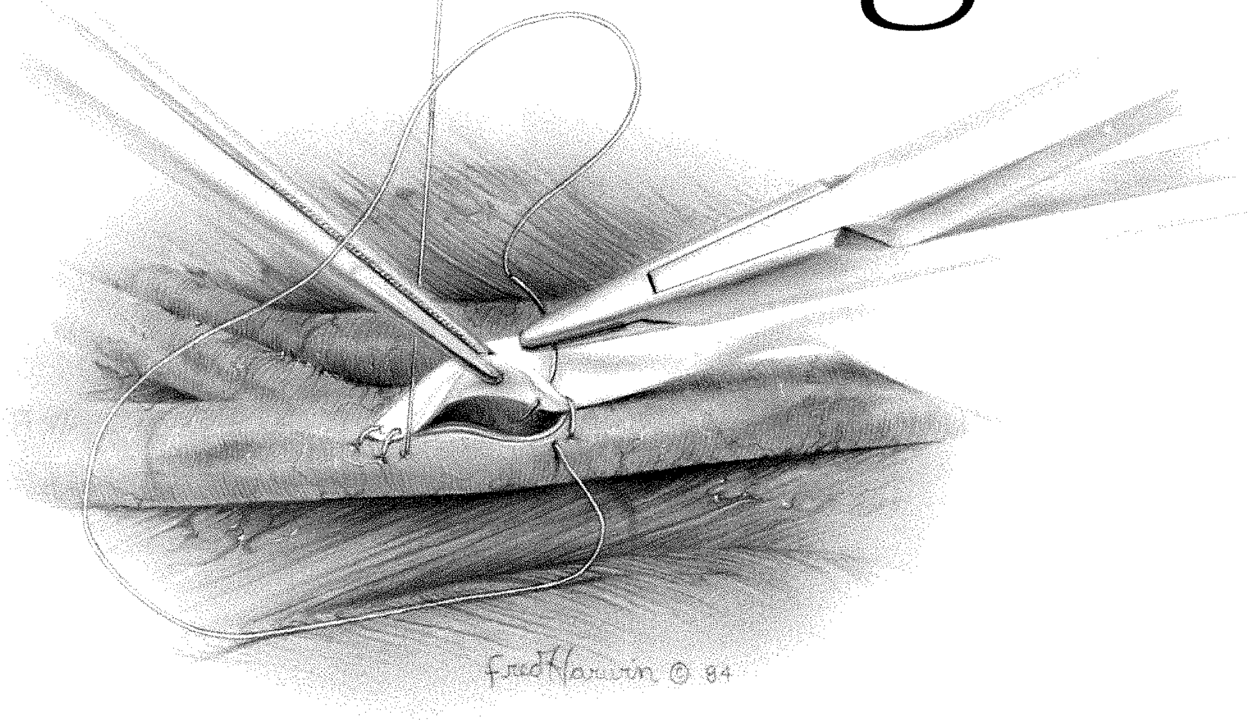
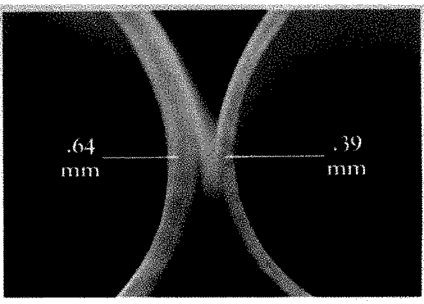
Thinner... with even better handling.



No matter how good a product, there are ways to make it even better. Over 15 years of experience with clinical implants has established the standard GORE-TEX® Vascular Graft as the leading prosthesis, proven in thousands of clinical cases.

Now there is a product that is even thinner and easier to use.

The Thin Walled GORE-TEX® Vascular Graft more closely matches the wall thickness of natural vessels. Substantially thinner than our standard graft, the Thin Walled Graft allows for a more precise anastomosis, and it meets the same high quality requirements of the standard graft. The Thin Walled Graft maintains excellent suture retention, yet is easier to handle.



The Thin Walled GORE-TEX Vascular Graft (right) shown in contrast to the standard graft, in 6mm diameters.

To ensure proper fit the Thin Walled Graft is readily available in a range of diameters from 3mm to 10mm, and in both ringed and non-ringed configurations.

The Thin Walled GORE-TEX Vascular Graft
- is biocompatible
- does not require pre-clotting
- resists aneurysmal dilatation
- resists the spread of infection

And is even thinner and easier to handle than the standard graft.

For more information please use the coupon below or call toll free, 800-638-4804.

Thin Walled GORE-TEX® Vascular Graft.

☐ Please send me a complete bibliography on GORE-TEX Vascular Grafts.

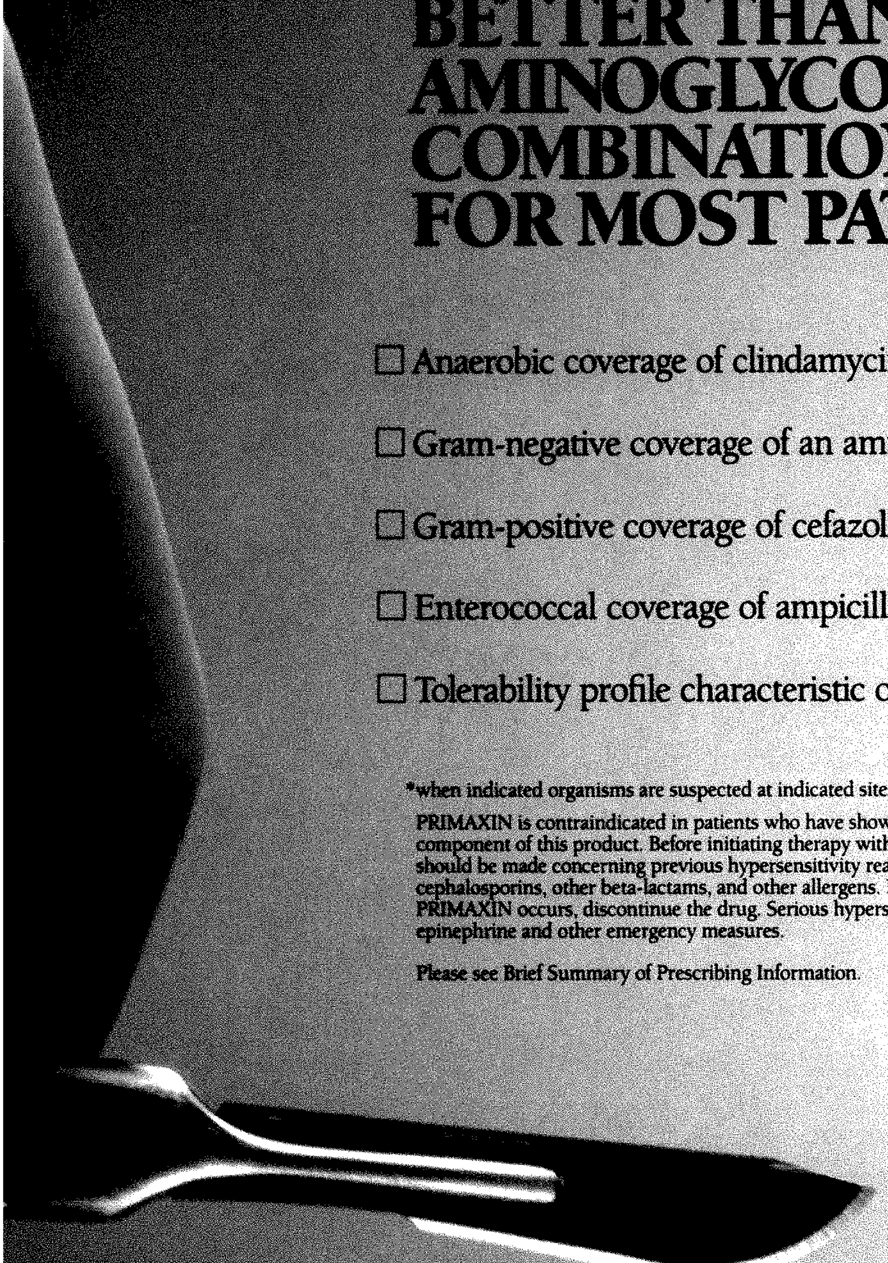
PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product. Before initiating therapy with PRIMAXIN, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, other beta-lactams, and other allergens. If an allergic reaction to PRIMAXIN occurs, discontinue the drug. Serious hypersensitivity reactions may require epinephrine and other emergency measures.

Please see Brief Summary of Prescribing Information.



INTRAVENOUS

PRIMAXIN®

(Imipenem-Cilastatin Sodium|MSD)

Contraindications: PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product.

Warnings: SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (anaphylactic) REACTIONS HAVE BEEN REPORTED IN PATIENTS RECEIVING THERAPY WITH BETA LACTAMS. THESE REACTIONS ARE MORE APT TO OCCUR IN PERSONS WITH A HISTORY OF SENSITIVITY TO MULTIPLE ALLERGENS.

THERE HAVE BEEN REPORTS OF PATIENTS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE HYPERSENSITIVITY REACTIONS WHEN TREATED WITH ANOTHER BETA LACTAM. BEFORE INITIATING THERAPY WITH 'PRIMAXIN,' CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, OTHER BETA LACTAMS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION TO 'PRIMAXIN' OCCURS, DISCONTINUE THE DRUG. SERIOUS HYPERSENSITIVITY REACTIONS MAY REQUIRE EPINEPHRINE AND OTHER EMERGENCY MEASURES.

Pseudomembranous colitis has been reported with virtually all antibiotics, including PRIMAXIN; therefore it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use. This colitis may range in severity from mild to life threatening.

Mild cases of pseudomembranous colitis may respond to drug discontinuance alone. In more severe cases, management may include sigmoidoscopy, appropriate bacteriological studies, fluid, electrolyte, and protein supplementation, and the use of a drug such as oral vancomycin, as indicated. Isolation of the patient may be advisable. Other causes of colitis should also be considered.

Precautions: *General*—CNS adverse experiences such as confusional states, myoclonic activity, and seizures have been reported during treatment with PRIMAXIN, especially when recommended dosages were exceeded. These experiences have occurred most commonly in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function. However, there have been reports of CNS adverse experiences in patients who had no recognized or documented underlying CNS disorder or compromised renal function.

Patients with severe or marked impairment of renal function, whether or not undergoing hemodialysis, had a higher risk of seizure activity when receiving maximum recommended doses than those with no impairment of renal function; therefore, maximum recommended doses should be used only where clearly indicated (see DOSAGE AND ADMINISTRATION).

Patients with creatinine clearances of ≤ 5 mL/min/1.73 m^2 should not receive PRIMAXIN unless hemodialysis is instituted within 48 hours.

For patients on hemodialysis, PRIMAXIN is recommended only when the benefit outweighs the potential risk of seizures.

Close adherence to the recommended dosage and dosage schedules is urged, especially in patients with known factors that predispose to convulsive activity. Anticonvulsant therapy should be continued in patients with known seizure disorders. If focal tremors, myoclonus, or seizures occur, patients should be evaluated neurologically, placed on anticonvulsant therapy if not already instituted, and the dosage of PRIMAXIN re-examined to determine whether it should be decreased or the antibiotic discontinued.

As with other antibiotics, prolonged use of PRIMAXIN may result in overgrowth of nonsusceptible organisms. Repeated evaluation of the patient's condition is essential. If superinfection occurs during therapy, appropriate measures should be taken. While PRIMAXIN possesses the characteristic low toxicity of the beta-lactam group of antibiotics, periodic assessment of organ system function during prolonged therapy is advisable.

Drug Interactions—Since concomitant administration of PRIMAXIN and probenecid results in only minimal increases in plasma levels of imipenem and plasma half-life, it is not recommended that probenecid be given with PRIMAXIN.

PRIMAXIN should not be mixed with or physically added to other antibiotics. However, PRIMAXIN may be administered concomitantly with other antibiotics, such as aminoglycosides.

Carcinogenesis, Mutagenesis, Impairment of Fertility—Gene toxicity studies were performed in a variety of bacterial and mammalian tests *in vivo* and *in vitro*. The tests were: V79 mammalian cell mutation assay (PRIMAXIN alone and imipenem alone), Ames test (cilastatin sodium alone), unscheduled DNA synthesis assay (PRIMAXIN), and *in vivo* mouse cytogenicity test (PRIMAXIN). None of these tests showed any evidence of genetic damage.

Reproduction tests in male and female rats were performed with PRIMAXIN at dosage levels up to 8 times the usual human dose. Slight decreases in live fetal body weight were restricted to the highest dosage level. No other adverse effects were observed on fertility, reproductive performance, fetal viability, growth, or postnatal development of pups. Similarly, no adverse effects on the fetus or on lactation were observed when PRIMAXIN was administered to rats late in gestation.

Pregnancy—Pregnancy Category C: Teratogenicity studies with cilastatin sodium in rabbits and rats at 10 and 33 times the usual human dose, respectively, showed no evidence of adverse effect on the fetus. No evidence of teratogenicity or adverse effect on postnatal growth or behavior was observed in rats given imipenem at dosage levels up to 30 times the usual human dose. Similarly, no evidence of adverse effect on the fetus was observed in teratology studies in rabbits with imipenem at dosage levels at the usual human dose.

Teratology studies with PRIMAXIN at doses up to 11 times the usual human dose in pregnant mice and rats during the period of major organogenesis revealed no evidence of teratogenicity.

Data from preliminary studies suggest an apparent intolerance to PRIMAXIN (including emesis, inappetence, body weight loss, diarrhea, and death) at doses equivalent to the average human dose in pregnant rabbits and cynomolgus monkeys that is not seen in non-pregnant animals in these or other species. In other studies, PRIMAXIN was well tolerated in equivalent or higher doses (up to 11 times the average human dose) in pregnant rats and mice. Further studies are under way to evaluate these findings.

There are, however, no adequate and well-controlled studies in pregnant women. PRIMAXIN should be used only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers—It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when PRIMAXIN is administered to a nursing woman.

Pediatric Use—Safety and effectiveness in infants and children below 12 years of age have not yet been established.

Adverse Reactions: PRIMAXIN is generally well tolerated. Many of the 1,723 patients treated in clinical trials were severely ill and had multiple background diseases and physiological impairments, making it difficult to determine causal relationship of adverse experiences to therapy with PRIMAXIN.

Local Adverse Reactions—Local adverse clinical reactions that were reported as possibly, probably, or definitely related to therapy with PRIMAXIN were: phlebitis/thrombophlebitis (3.1%), pain at the injection site (0.7%), erythema at the injection site (0.4%), vein induration (0.2%), infused vein infection (0.1%).

Systemic Adverse Reactions—The most frequently reported systemic adverse clinical reactions that were reported as possibly, probably, or definitely related to PRIMAXIN were: nausea (2.0%), diarrhea (1.8%), vomiting (1.5%), rash (0.9%), fever (0.5%), hypotension (0.4%), seizures (0.4%) (see PRECAUTIONS), dizziness (0.3%), pruritus (0.3%), urticaria (0.2%), somnolence (0.2%).

Additional adverse systemic clinical reactions reported as possibly, probably, or definitely drug related occurring in less than 0.2% of the patients or reported since the drug was marketed are listed within each body system in order of decreasing severity: *Gastrointestinal*—pseudomembranous colitis (see WARNINGS), hemorrhagic colitis, gastroenteritis, abdominal pain, glossitis, tongue papillar hypertrophy, heartburn, pharyngeal pain, increased salivation; *CNS*—encephalopathy, tremor, confusion, myoclonus, paresthesia, vertigo, headache, psychic disturbances; *Special Senses*—transient hearing loss in patients with impaired hearing, tinnitus; *Respiratory*—chest discomfort, dyspnea, hyperventilation, thoracic spine pain; *Cardiovascular*—palpitations, tachycardia; *Renal*—oliguria/anuria, polyuria; *Skin*—erythema multiforme, facial edema, flushing, cyanosis, hyperhidrosis, skin texture changes, candidiasis, pruritus vulvae; *Body as a Whole*—polyarthralgia, asthenia/weakness.

Adverse Laboratory Changes—Adverse laboratory changes without regard to drug relationship that were reported during clinical trials or reported since the drug was marketed were: *Hepatic*—increased SGPT, SGOT, alkaline phosphatase, bilirubin, and LDH; *Hemic*—increased eosinophils, positive Coombs test, decreased WBC and neutrophils, including agranulocytosis, increased WBC, increased platelets, decreased platelets, decreased hemoglobin and hematocrit, increased monocytes, abnormal prothrombin time, increased lymphocytes, increased basophils; *Electrolytes*—decreased serum sodium, increased potassium, increased chloride; *Renal*—increased BUN, creatinine; *Urinalysis*—presence of urine protein, urine red blood cells, urine white blood cells, urine casts, urine bilirubin, and urine urobilinogen.

NOTE: Due to the high antimicrobial activity of PRIMAXIN, it is recommended that the maximum total daily dosage not exceed 50 mg/kg/day or 4.0 g/day, whichever is lower.

How Supplied: PRIMAXIN is supplied as a sterile powder mixture in vials, infusion bottles, and single-dose ADD-Vantage®† vials containing imipenem anhydrous and cilastatin sodium as follows: 250 mg imipenem equivalent and 250 mg cilastatin equivalent; 500 mg imipenem equivalent and 500 mg cilastatin equivalent.

Caution: The suspension from vials is not for direct infusion.

Publication of the Proceedings of the Southern Surgical Association

DAVID C. SABISTON, JR., M.D.

From the Department of Surgery, Duke University Medical Center, Durham, North Carolina

THE FIRST VOLUME of the *Transactions of the Southern Surgical Association* records the session held in Birmingham, Alabama, December 4–6, 1888 (Fig. 1). Attention is called to the fact that the Association was organized in 1887 and was first named the Southern Surgical and Gynecological Association. A review of this volume, with its 318 pages, is a fascinating experience because it is rich in the surgical thought and practices held in the United States a century ago. It was published by the Caldwell Printing Company in Birmingham, Alabama in 1889, the year after the first session, and the title page of the first issue of the *Transactions* is shown in Figure 2. Features that appear in Volume I include the Minutes of the first annual session which was held on Tuesday, December 4, 1888. The meeting was called to order at 10:00 A.M. by the President, Dr. W. D. Haggard of Nashville, with 41 members and more than 50 visitors in attendance (Fig. 3).

The Mayor of Birmingham, the Honorable A. O. Lane, delivered the Welcoming Address and he said: "Gentlemen of the Southern Surgical and Gynecological Association:—Perhaps there is no duty to which the chief magistrate of a city turns with more genuine pleasure from the cares and burdens of official life than that of extending greetings to the city's guests; and, on this occasion, that pleasure is greatly heightened by the presence of a body of men whose lives are devoted to mitigating human suffering and preserving human life. A profession glowing with such benignant aims and illustrated by the heroic self-sacrifice of the great body of its members finds a warm place in the hearts of a generous and appreciative public. Therefore, as the organ of open-handed, warm-hearted Birmingham, I bid you doubly welcome and extend to you the cordial hospitalities of the people."

After the Business Meeting that morning, Dr. J. D. S. Davis, Chairman of the Committee on Arrangements, described the Scientific Program which had been prepared by the Committee. It is interesting that local hosts and officials of Birmingham apparently had planned a number of special events in addition to the scientific sessions, since Dr. Davis reported: "The Association, however, had to decline a number of excursions which had been arranged by the local committee, as time would not permit their acceptance." At the Business Meeting, Dr. Bedford Brown moved that the membership of the Association be limited to 100 and this was referred to the Judicial Council. The Scientific Session then proceeded with the annual address of President Haggard.

It is interesting that the first page contains a notice stating, "The Committee of Publication, after due consideration, decided that it would not be wise to attempt to include the discussions of papers in the volume of Transactions, since it was impossible to get a satisfactory report of the discussions from the members after they had returned to their homes. Hereafter the Association will have a stenographer, and a full report of all discussions will be preserved." This is a very significant comment, since those who have attended the annual meetings of the Southern Surgical Association clearly recognize that the discussions form an extraordinarily important part of the scientific program. The following year, the prediction that a stenographer would be present was fulfilled, and since then the printed discussion has always been recorded in detail. In fact, the discussions are at times longer than the original paper. The

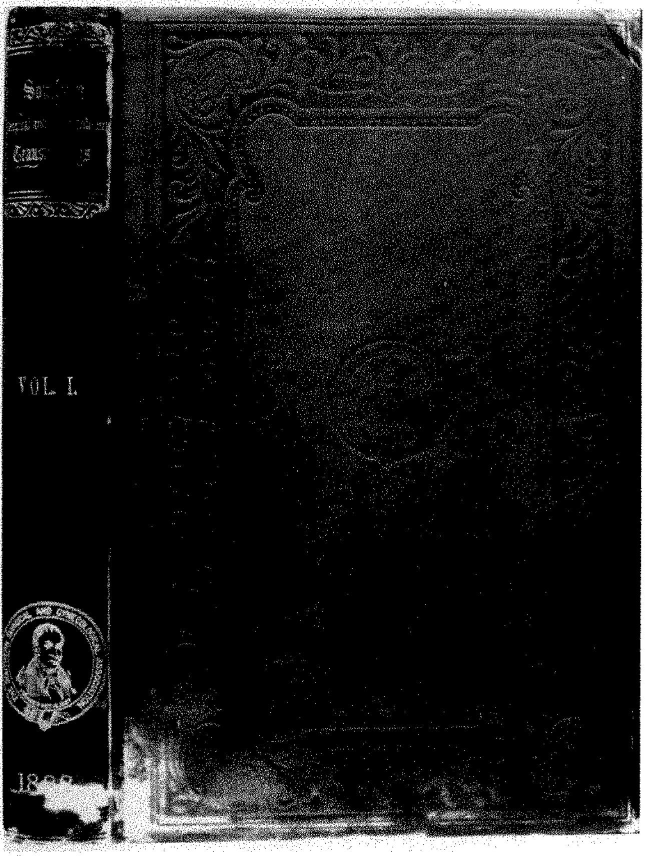

FIG. 1. Volume I of *Transactions* (from *Transactions of the Southern Surgical and Gynecological Association,* Volume I, 1888).

content of the discussions of that day was outstanding, and this feature has continued as a characteristic hallmark of the Association to the present.

The second page of Volume I of the *Transactions* lists the officers for the year 1888–1889 with Hunter McGuire as President (Fig. 4). It will be recalled that he was at the time generally regarded as the most outstanding surgeon in the South, having been a medical officer in the Confederate Army during the War between the States and the surgeon to General T. J. "Stonewall" Jackson. As has continued to the present day, in the original choice of officers, considerable attention was given both to the professional stature of those selected and recognition of geographic location. In the list of officers shown in Figure 4, the states of Tennessee, Virginia, Georgia, Alabama, Mississippi, and Kentucky are each represented.

The second annual meeting of the Association was held in Nashville on Tuesday, Wednesday, and Thursday, November 12, 13, and 14, 1889 (Fig. 5). Dr. Hunter McGuire delivered the Presidential Address at the *evening session* following the annual dinner, and it was described as being "heartily applauded" (Fig. 6). It is to be assumed that it was a delightful occasion, and perhaps a lengthy one, and most likely filled with a great deal of camaraderie since the Morning Session on the next day did not begin until 10:00 A.M.

In this Address Hunter McGuire referred to some of his experiences in the War between the States saying: "Many of the medical officers of this Corps were wounded or killed on the field. One, I saw fall at Strasburg, amid the cheers of soldiers at the evidence he gave of devotion to duty; another at Sharpsburg, facing an assault before which even veterans quailed and fled; and a third I found upon the bloody field of Cold Harbor, dying with a shell-wound through his side. As I knelt down beside him and told him his wound was mortal, he answered, 'I am no more afraid to die than I was afraid to do my duty'." One can easily understand why a reader of this Address many years ago was moved to pencil the word "Great" in the margin.

FIRST ANNUAL MEETING.

FIRST DAY.

TUESDAY, DECEMBER 4, 1888.

Morning Session.

The meeting was called to order at 10 a. m. by the President, Dr. W. D. Haggard. There were in attendance forty-one members and more than fifty visitors.

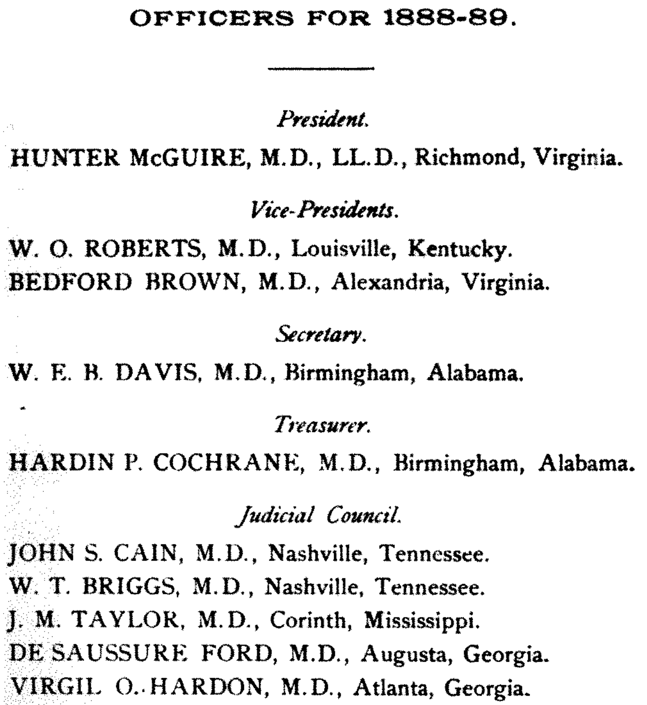
After an eloquent prayer, by Rev. Dr. D. I. Purser, of Birmingham, Hon. A. O. Lane, Mayor of the city, delivered the following address of welcome:

Gentlemen of the Southern Surgical and Gynecological Association:—Perhaps there is no duty to which the chief magistrate of a city turns with more genuine pleasure from the cares and burdens of official life than that of extending greeting to the city's guests; and, on this occasion, that pleasure is greatly heightened by the presence of a body of men whose

FIG. 3. First Annual Meeting, First Day (from *Transactions of the Southern Surgical and Gynecological Association,* Volume I, 1888).

Although the first volume of the *Transactions* was published in Birmingham, all subsequent issues of the *Transactions* through the year 1931 were published by the Dornan Printers in Philadelphia. This company used the same binding and format throughout the entire period. In retrospect, it is fascinating that this annual volume of the *Transactions* was the *only* recording of the scientific proceedings of the Southern Surgical Association to be published. In addition to the Presidential Addresses and the Minutes of the Business Meetings, all scientific papers with the discussions were recorded in them for each session. Copies of the *Transactions* were sent to the membership, as well as to medical libraries in this country and in Europe, but the annual distribution never exceeded 300 copies. It is apparent that much important surgical data were made available only to a relatively small readership.

At the 41st annual meeting of the Association in 1928, the significance of the limited coverage given the annual scientific program was discussed by the Council.



OFFICERS FOR 1888-89.

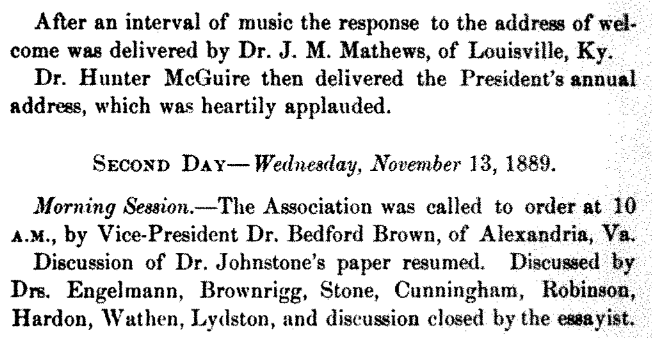
MINUTES OF THE PROCEEDINGS
AT THE
SECOND ANNUAL MEETING
OF
THE SOUTHERN
SURGICAL AND GYNECOLOGICAL
ASSOCIATION,
HELD IN THE
SENATE CHAMBER OF THE CAPITOL,
Nashville, Tennessee,
NOVEMBER 12, 13, AND 14, 1889.

FIG. 5. Second Annual Meeting (from *Transactions of the Southern Surgical and Gynecological Association,* Volume II, 1889).



After an interval of music the response to the address of welcome was delivered by Dr. J. M. Mathews, of Louisville, Ky.

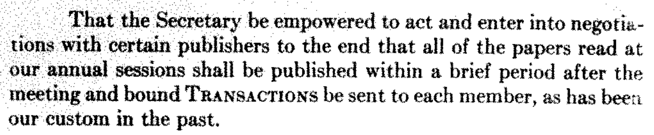
Dr. Hunter McGuire then delivered the President's annual address, which was heartily applauded.

SECOND DAY—*Wednesday, November* 13, 1889.

Morning Session.—The Association was called to order at 10 A.M., by Vice-President Dr. Bedford Brown, of Alexandria, Va.

Discussion of Dr. Johnstone's paper resumed. Discussed by Drs. Engelmann, Brownrigg, Stone, Cunningham, Robinson, Hardon, Wathen, Lydston, and discussion closed by the essayist.

FIG. 6. Minutes, Second Annual Meeting (from *Transactions of the Southern Surgical and Gynecological Association,* Volume II, 1889).



That the Secretary be empowered to act and enter into negotiations with certain publishers to the end that all of the papers read at our annual sessions shall be published within a brief period after the meeting and bound TRANSACTIONS be sent to each member, as has been our custom in the past.

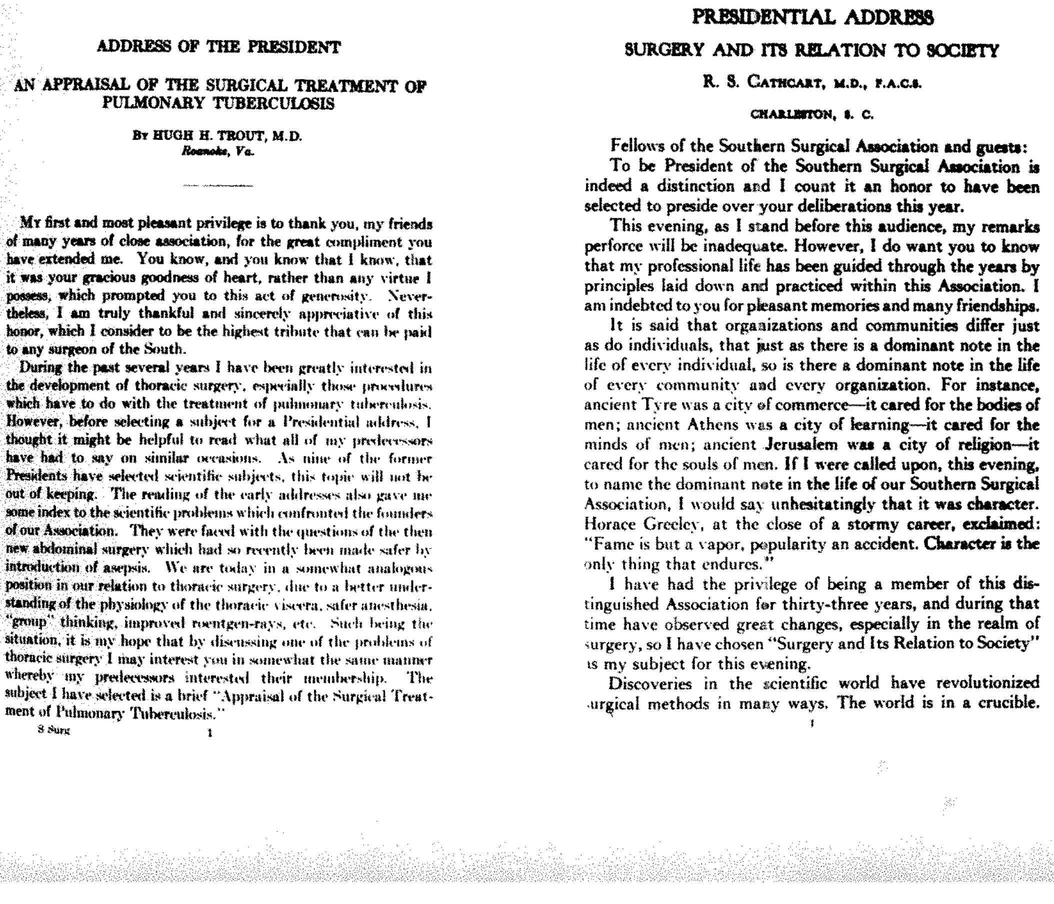
FIG. 7. 41st Annual Meeting resolution (from *Transactions of the Southern Surgical Association,* Volume 41, 1928).

In the Minutes of this meeting, one finds the following resolution: "That the Secretary be empowered to act and enter into negotiations with certain publishers to the end that all of the papers read at our annual scientific sessions shall be published within a brief period after the meeting and bound *Transactions* be sent to each member, as has been our custom in the past" (Fig. 7). Apparently little transpired during that year because the Minutes of the following annual session contained the statement: "That your Secretary continue to negotiate with certain publishers, etc." Progress was slow in making these arrangements originally recommended by the Council, and 3 years later, in 1932, it was recorded in the Minutes: "That the proposition made to the Southern Surgical Association by the *American Journal of Surgery* be accepted, and that the *American Journal of Surgery* be adopted as the official organ of the Southern Surgical Association for the publication of all papers read, together with the issuance of the *Transactions.*" This recommendation was adopted by the Association, and for the next 3 years the *Transactions* were printed by Paul B. Hoeber, Inc. of New York, the publishers of the *American Journal of Surgery.*

Although the size of the volumes was approximately the same as those previously prepared by the Dornan Company, the print was different (Fig. 8) than the type used in the last issue published by the Dornan Company shown on the left and that by Paul B. Hoeber, Inc. in 1932 on the right. During these years, most of the papers presented at the annual meeting were published in the *American Journal of Surgery* in its May and June issues.

In 1934, a youthful and dynamic figure who was subsequently to achieve worldwide acclaim, Alton Ochsner of New Orleans, was elected as Secretary of the Southern Surgical Association, being only the fifth elected to this office in the 48 years since the founding of the Association (Fig. 9). In 1935, the *Transactions* was published by the J. B. Lippincott Company of Philadelphia, and since then this relationship has been maintained for over half a century.

As had occurred previously, there was a slight change in format between the last issue of the *Transactions* by Hoeber and the first by Lippincott (Fig. 10). Since then, papers presented at the Southern Surgical Association have appeared in *Annals of Surgery* in the May and June issues. In Volume 103, January–June, 1936, the masthead read: "Annals of Surgery—Also the Official Publication of the American Surgical Association and of the Southern Surgical Association." One of the greatest secretaries of the Southern Surgical Association, Alton Ochsner, arranged for publication of a separate index



ADDRESS OF THE PRESIDENT

AN APPRAISAL OF THE SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS

BY HUGH H. TROUT, M.D.
Roanoke, Va.

MY first and most pleasant privilege is to thank you, my friends of many years of close association, for the great compliment you have extended me. You know, and you know that I know, that it was your gracious goodness of heart, rather than any virtue I possess, which prompted you to this act of generosity. Nevertheless, I am truly thankful and sincerely appreciative of this honor, which I consider to be the highest tribute that can be paid to any surgeon of the South.

During the past several years I have been greatly interested in the development of thoracic surgery, especially those procedures which have to do with the treatment of pulmonary tuberculosis. However, before selecting a subject for a Presidential address, I thought it might be helpful to read what all of my predecessors have had to say on similar occasions. As nine of the former Presidents have selected scientific subjects, this topic will not be out of keeping. The reading of the early addresses also gave me some index to the scientific problems which confronted the founders of our Association. They were faced with the questions of the then new abdominal surgery which had so recently been made safer by introduction of asepsis. We are today in a somewhat analogous position in our relation to thoracic surgery, due to a better understanding of the physiology of the thoracic viscera, safer anesthesia, "group" thinking, improved roentgen-rays, etc. Such being the situation, it is my hope that by discussing one of the problems of thoracic surgery I may interest you in somewhat the same manner whereby my predecessors interested their membership. The subject I have selected is a brief "Appraisal of the Surgical Treatment of Pulmonary Tuberculosis."

8 Surg 1

PRESIDENTIAL ADDRESS

SURGERY AND ITS RELATION TO SOCIETY

R. S. CATHCART, M.D., F.A.C.S.

CHARLESTON, S. C.

Fellows of the Southern Surgical Association and guests:

To be President of the Southern Surgical Association is indeed a distinction and I count it an honor to have been selected to preside over your deliberations this year.

This evening, as I stand before this audience, my remarks perforce will be inadequate. However, I do want you to know that my professional life has been guided through the years by principles laid down and practiced within this Association. I am indebted to you for pleasant memories and many friendships.

It is said that organizations and communities differ just as do individuals, that just as there is a dominant note in the life of every individual, so is there a dominant note in the life of every community and every organization. For instance, ancient Tyre was a city of commerce—it cared for the bodies of men; ancient Athens was a city of learning—it cared for the minds of men; ancient Jerusalem was a city of religion—it cared for the souls of men. If I were called upon, this evening, to name the dominant note in the life of our Southern Surgical Association, I would say unhesitatingly that it was character. Horace Greeley, at the close of a stormy career, exclaimed: "Fame is but a vapor, popularity an accident. Character is the only thing that endures."

I have had the privilege of being a member of this distinguished Association for thirty-three years, and during that time have observed great changes, especially in the realm of surgery, so I have chosen "Surgery and Its Relation to Society" as my subject for this evening.

Discoveries in the scientific world have revolutionized surgical methods in many ways. The world is in a crucible.

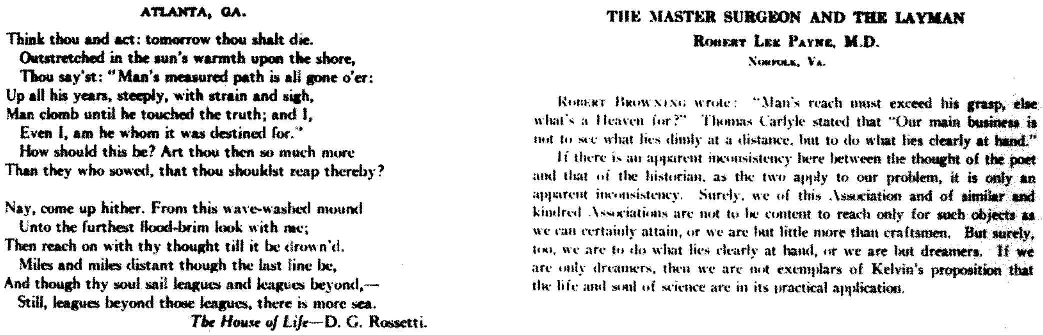
summarizing the recordings of the *Transactions* for the first 50 years. This volume was published in 1940 with 133 pages and the subject and author headings were combined into an index and published by the J. B. Lippincott Company (Fig. 11).

The meeting of 1942 was cancelled because of World War II when professional meetings were withheld at the request of the Federal Government. In 1943, the Southern Surgical Association resumed its annual meeting, and the 55th session was held at the Roosevelt Hotel in



PRESIDENTIAL ADDRESS
PROGRESS IN SURGERY

FRANK K. BOLAND, M.D.

ATLANTA, GA.

Think thou and act: tomorrow thou shalt die.
  Outstretched in the sun's warmth upon the shore,
  Thou say'st: "Man's measured path is all gone o'er:
Up all his years, steeply, with strain and sigh,
Man clomb until he touched the truth; and I,
  Even I, am he whom it was destined for."
  How should this be? Art thou then so much more
Than they who sowed, that thou shouldst reap thereby?

Nay, come up hither. From this wave-washed mound
  Unto the furthest flood-brim look with me;
Then reach on with thy thought till it be drown'd.
  Miles and miles distant though the last line be,
And though thy soul sail leagues and leagues beyond,—
  Still, leagues beyond those leagues, there is more sea.

The House of Life—D. G. Rossetti.

PRESIDENTIAL ADDRESS

THE MASTER SURGEON AND THE LAYMAN

ROBERT LEE PAYNE, M.D.

NORFOLK, VA.

ROBERT BROWNING wrote: "Man's reach must exceed his grasp, else what's a Heaven for?" Thomas Carlyle stated that "Our main business is not to see what lies dimly at a distance, but to do what lies clearly at hand."

If there is an apparent inconsistency here between the thought of the poet and that of the historian, as the two apply to our problem, it is only an apparent inconsistency. Surely, we of this Association and of similar and kindred Associations are not to be content to reach only for such objects as we can certainly attain, or we are but little more than craftsmen. But surely, too, we are to do what lies clearly at hand, or we are but dreamers. If we are only dreamers, then we are not exemplars of Kelvin's proposition that the life and soul of science are in its practical application.

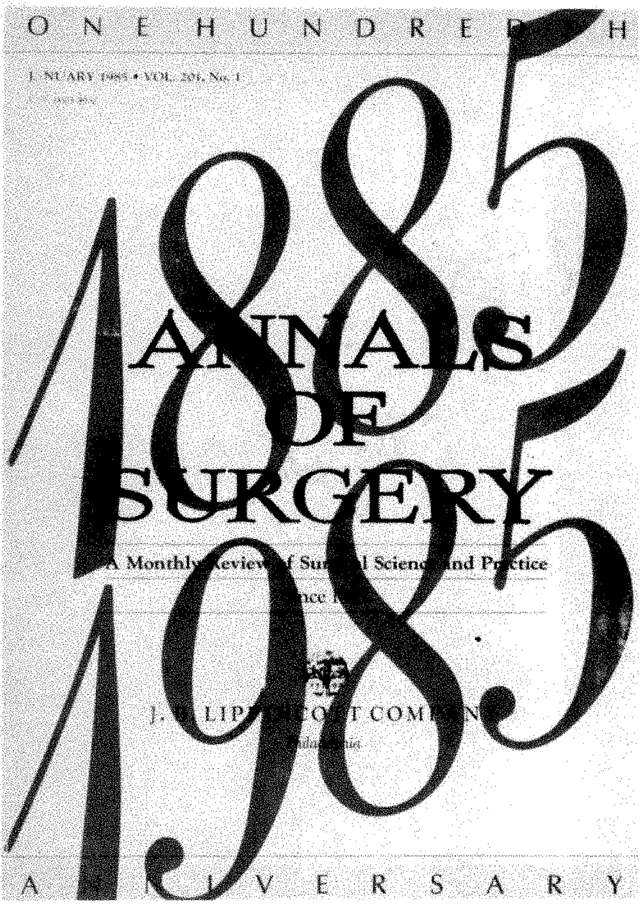

FIG. 12. Cover page of *Annals of Surgery* Centennial Year (from *Annals of Surgery*, Volume 201:1, 1985).

New Orleans with 125 members present. Alton Ochsner was elected President that year and Alfred Blalock became the new Secretary.

In 1985, *Annals of Surgery* celebrated its Centennial and used a somewhat different format for the cover page for the 12 months in that year (Fig. 12). *Annals of Surgery* first appeared in January 1885, and today it is recognized as the oldest journal published in English devoted exclusively to surgery. On the first page of the Centennial issue, one finds the Statement of the Publisher, Mr. John Wehner, who said: "This year, 1985, is *Annals of Surgery*'s 100th birthday. It is a remarkable achievement for a medical journal to have bridged a span of 100 years of change and to have maintained a position of eminence and leadership over the past century of surgical progress." Further in this commentary, he paid great tribute to the members of the Editorial Board who, as he said, "review every manuscript" as well as those who form the editorial process.

The Editorial Board of *Annals of Surgery* has been fortunate to have among its members through the past century a number of outstanding master surgeons and unquestioned leaders in the field. Of interest to members of the Southern Surgical Association is the fact that currently 17 of the members of the Editorial Board are also members of the Southern Surgical Association (Fig. 13). This emphasizes both the significance of the Southern Surgical Association and the recognition it receives by *Annals of Surgery*, as well as the fact that this Association has from its outset maintained a policy of selection of members from outstanding figures in surgery *throughout the nation* and not solely those from the Southern States. In this connection, it is interesting to review the issue of *Transactions* that recorded the 1890 meeting in Atlanta in which one finds the following statement by R. B. Maury of Memphis: ". . . This society, as its name implies, is distinctively Southern, but it is not exclusively so, for it has opened wide its doors with a hearty welcome to distinguished men of ability from all sections of our common country. Its membership, although it is now only in the third year of its existence, has reached the phenomenal growth of 100 members, and among those members I may say that we are proud to claim some of the most distinguished men to be found in the ranks of surgery and gynecology." Through the years, the entire membership has recognized the significance of this point of view in providing

great strength, depth, and breadth at the annual scienific meetings of the Southern Surgical Association.

Also in the first issue of the Centennial Year of *Annals of Surgery* is a commentary on "The First 100 Years: Annals of Surgery and a Century of Progress." The hisory of the founding of *Annals of Surgery* is noted to have begun as a concept of Lewis S. Pilcher. The title page of the first issue of *Annals of Surgery* in 1885 is shown in Figure 14. Pilcher was a remarkable individual, a tireless worker who early brought prominence to he Journal (Fig. 15).

It is interesting that early in 1885 the *Canadian Medical and Surgical Journal* stated editorially: "We have received the prospectus of a new medical monthly called he *Annals of Surgery.* It is to be devoted entirely to surgery and it is intended to be representative of the surgical thought and work of the present day. The Journal will appear on the first day of each month, simultaneous in the United States and Great Britain. This is the first attempt, as far as we know, to publish in the English language, a periodical exclusively devoted to surgery. We wish the enterprise every success and feel sure that it will be supported by both British and American surgeons."

ANNALS

OF

SURGERY

A MONTHLY REVIEW

OF SURGICAL SCIENCE AND PRACTICE

EDITED BY

LEWIS S. PILCHER, A.M., M.D.,

AND

CHARLES B. KEETLEY, F.R.C.S.

VOL. I.

January—June, 1885.

FIG. 14. Title page, 1st issue of *Annals of Surgery,* 1885 (from *Annals of Surgery,* Volume 201:1, 1985).

Since 1897, the sole publisher of *Annals of Surgery* has been the J. B. Lippincott Company, which is thoroughly committed to the highest standards of publishing with an established policy of maintaining excellence in every aspect of the field. The firm has entrusted complete responsibility for the decision-making process concerning manuscripts accepted for publication entirely to the Editorial Board. It is remarkable that in the first 6 issues of *Annals of Surgery* there were a total of 51 authors, 22 of whom were from the British Isles and Canada. Among the contributors was Lewis Atterbury Stimson, the noted Professor of Surgery at Columbia University and Presbyterian Hospital in New York, who reviewed the use of the ligature in the treatment of aneurysms. On the 20th anniversary of *Annals of Surgery,* the *Montreal Medical Journal* noted: "The December issue of the *Annals of Surgery* sustains a verdict that it achieved an undisputed place as a leading exponent of surgery in the English language. This issue signalizes the close of the first 20 years of publication of this journal, and the publishers have properly marked the event by issuing a Festschrift number, which is more than double the annual size, and is remarkable for the value of its contents, the number and quality of its contributors, and the abundance and quality of its illustrations."

It is further remarkable that Lewis Pilcher was Editor for 50 continuous years and is seen in Figure 16 in his later years (1930). Shortly after he had completed the

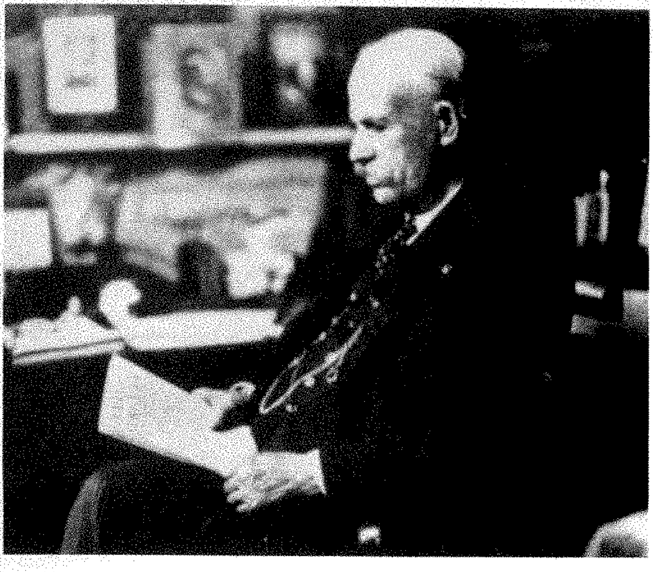

FIG. 16. Lewis S. Pilcher, 1930, age 85 (from *Annals of Surgery,* Volume 201:1, 1985).

December issue of 1934, he died quietly, having led the Journal so effectively for a remarkable period.

As *Annals of Surgery* enters its second century, and 52nd year of publishing the *Transactions of the Southern Surgical Association,* the Journal is currently being sent to subscribers in 117 nations around the world. Each year the May and June issues are exceedingly strong, recording as they do the scientific papers presented at this Annual Meeting. The same is true of the September and October issue each year as these contain the presentations made at the Annual Meeting of the American Surgical Association.

Reflecting on all issues of the *Transactions* during the past century, it is obvious that the Southern Surgical Association has been the site of extraordinary accounts of major advances in surgery as well as reviews of the state of the art at different periods. Today, it is difficult to obtain a complete series of the *Transactions,* as might well be expected, but fortunately, a number are present in libraries throughout the nation. From inception to the present, the Southern Surgical Association has been a highly revered and respected annual surgical scientific session with the highest standards of scientific excellence. *Tradition* is a very important part of this very special organization—but, the leadership and membership alike have always known that, as T. S. Eliot so wisely said: "Tradition cannot be inherited, and if you want it you must obtain it by *great* labor." All members can take much pride in our surgical heritage as the Southern Surgical Association approaches the second century of this *great,* and distinctively *unique,* organization and will surely continue to *work* for it and its annual scientific sessions in the future as in the past.

The Collection and Preservation of the Archives of the Southern Surgical Association

ROBERT S. SPARKMAN, M.D., LL.D.

From the Department of Surgery, Baylor University Medical Center, Dallas, Texas

THE COUNCIL OF THE SOUTHERN SURGICAL ASSOCIATION, in 1891, in anticipation of its forthcoming centenary in 1987, recommended the appointment of a committee that was given the responsibility of making plans for the celebration and commemoration of that event. The following year a committee of three was named for this purpose, consisting of Drs. David C. Sabiston of Durham, G. Rainey Williams of Oklahoma City, and Robert S. Sparkman of Dallas as chairman. Dr. J. D. Martin of Atlanta was appointed as a special consultant to the committee, and a year later Dr. Laman A. Gray, Sr. of Louisville was also added.

In 1984, the committee was given the additional responsibility of seeking and arranging for a university library to serve as the permanent repository for the archives of the Association. It was understood that an additional duty of the committee would be to search for and to assemble the items of historical interest that would comprise the organizational archive.

As is so often the case in scientific societies, there had never been any serious effort in the Southern Surgical Association to maintain a comprehensive collection of historical documents and memorabilia. From 1956 to 1965, provision had been made in the By-Laws for the office of Historian, but little if anything was accomplished and the office was soon terminated. During most of its first century, the entire scientific and historical record of the Association was contained in the programs, the attendance rosters, the secretary's newsletters, the annual volume of *Transactions,* and the manuscripts published in the *American Journal of Surgery* (1932, 1933 and 1934 meetings) or in *Annals of Surgery* (1935 meeting to the present).

Collection of the Archives

In 1984, a serious effort was begun by the committee to acquire items for an archival collection. The assistance of members of the organization and their families was sought, with gratifying results. One of the first efforts was to obtain photographs of all of the presidents, from the first, W. D. Haggard of Nashville, to the current, John L. Sawyers, also of Nashville. Eventually all of them were acquired.

A search was also begun for reprints of the presidential addresses. Except for the year 1957 (the presidential year of Floyd W. McRae of Atlanta), the collection is complete for the last 33 years. However, for the first 66 years only eight reprints of presidential addresses could be located, including the following: Hunter H. McGuire, 1889; Stuart McGuire, 1909; LeGrand Guerry, 1924; Hubert A. Royster, 1926; Albert O. Singleton, 1939; Alton Ochsner, 1944; and Daniel C. Elkin, 1946.

During the first half-century of the Association, the secretary compiled the attendance roster from memory and by recognition of those present. In time this became an impossible task, and in 1938, at the beginning of the second half-century, Secretary Alton Ochsner of New Orleans instituted a signature roster, using loose leaf ledger pages. All of them have been preserved. Currently, similar pages are used to record the attendance of guests. There is no record to indicate when this practice was begun, and unfortunately these pages have been discarded or destroyed.

Presented at the 100th Anniversary Meeting of The Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests and correspondence: Robert S. Sparkman, M.D., 1004 No. Washington, Dallas, TX 75204.

Submitted for publication: January 14, 1988.

No one knows when the first programs of the scientific sessions were printed and distributed. The earliest in the archival collection is for 1926. The series is complete from 1947 to the present, a period of 41 years. Each year the secretary mails the programs to members in advance of the meeting, along with two other booklets. One of these, the Family Register, so indispensable and unique to this organization, was first published in 1952, during the secretarial term of John C. Burch of Nashville. The collection is complete except for 1954. The third booklet is the confidential list entitled Candidates for Fellowship, which also was first printed in 1952. This series is complete.

The Shipley Award of the Southern Surgical Association was instituted in 1956, and provided for the award annually of a medal to the new member judged to have given the best presentation. It was established in memory of Dr. Arthur M. Shipley, Professor of Surgery at the University of Maryland Medical School from 1920 to 1948, and member of the Association from 1927 until his death in 1955. The first recipient was Felda Hightower of Winston-Salem in 1958, for his 1957 presentation. During the 1987 meeting, Dr. Hightower formally presented his historically important medal to the Association for addition to the archival collection. Dr. George A. Hallenbeck, currently of California, winner for his presentation in 1973 during his tenure at the University of Alabama in Birmingham, also donated his medal for the same purpose, in absentia. Before the 100th anniversary meeting there had been 29 recipients of the Shipley Award. The archival collection contains photographs of all of them, and reprints or photocopies of their award-winning presentations, most of which have been autographed by the author.

Operations performed on United States Presidents during their terms of office always have been of immense public interest, both because of their enduring historical significance and because of their possible impact on national and international affairs. During his term of office, Dwight D. Eisenhower had a somewhat controversial operation for acute intestinal obstruction due to chronic regional enteritis. The operation was performed at Walter Reed Army Medical Center by Lt. Gen. Leonard Heaton, then Surgeon General of the Army. Dr. Isidor S. Ravdin of Philadelphia was flown from Chicago in Air Force One to participate in the preoperative study and the surgical procedure. Other team members included Brian Blades and General (then Lt. Col.) Thomas Whelan. All with the exception of Whelan were members of the Southern Surgical Association. In 1963, General Heaton presented a detailed report of the operation before the Association. A reprint of the presentation was subsequently sent to President Eisenhower, who graciously inscribed it and also provided an autographed photograph of himself.

Seven years later, in 1971, Maj. Gen. Carl Hughes, also a member, presented a follow-up report to the Association entitled "A Review of the late General Eisenhower's Operations." Mrs. Eisenhower, who had given her permission for this presentation, inscribed a reprint of the publication and provided an autographed photograph of herself.

In each instance the reprints were also autographed by the authors and co-authors. The complete collection will become a part of the organizational archive.

In 1904, the Association met in Birmingham, just 1 year after the accidental death of the Founder, W. E. B. Davis. In memory of Dr. Davis, a full-length bronze statue had been commissioned, to be executed by the distinguished sculptor, Giuseppe Moretti, who had achieved fame for his immense statue of Vulcan, which stands on a high bluff overlooking the city of Birmingham. In elaborate ceremonies open to the public and preceded by a parade, the Davis statue was unveiled before a large audience. A medal of identification was worn by members of the Association. The clasp bears the single word, "FELLOW," while the words "Birmingham, Dec. 13–15, 1904" are printed on the ribbon. The circular pendant is the seal of the Association, surrounded by an ornamental border. There is no mention of such a medal in the Minutes of the Association. The one such medal known to exist has been donated for the historical collection. As far as is known, this is the only occasion in the history of the Association when any sort of identification badge has ever been worn by the members.

There are other acquisitions of historical interest. One of these is a commemorative menu and banquet program of the fiftieth anniversary dinner of the Association, held at the Tutwiler Hotel in Birmingham on Wednesday evening, December 8, 1937. Another is a souvenir given to each member in 1931 by President Hugh H. Trout of Roanoke. This consists of a printed card in a narrow black frame that contains two small brick fragments. One of the fragments is identified as having come from the foundation of the "Great House" on Jamestown Island, Virginia, which served in 1628 as the first hospital in America. The other fragment came from the chimney of the building in Birmingham in which the Southern Surgical Association was organized in 1887. Two of these souvenirs are known to exist. The one that was the personal property of Dr. Trout has been donated to the Association.

Two excellent formal outdoor group photographs contributed by members depict the audience attending the 27th annual session at the Grove Park Inn in Asheville, North Carolina, in 1914, and those attending the 49th annual session at the Edgewater Gulf Hotel in Edgewater Park, Mississippi, in 1936. In the 1914 photograph the ladies are included. The collection also contains many informal photographs of the social events and the meeting places, taken by members and donated by them in response to requests of the Committee.

A recently acquired item of memorabilia is a block of marble presented to the Association by Arlie R. Mansberger of Augusta during his presidential year, 1986. It was recovered from the wall of an operating room in the old University of Maryland Hospital in which Dr. Arthur M. Shipley removed the first pheochromocytoma to have been diagnosed correctly before operation. The hospital has since been demolished.

For about 15 years nonprofessional audio tapes have been made of the presidential addresses and of the two business meetings that are regularly conducted by the Association. The second business meeting, which is the concluding event of the annual meeting, includes the presentation of the Shipley Medal, the election of new members and officers, and the response of the newly elected president. Informal photographs also have been made of these events. The cassette tapes and the photographs will become a part of the archival collection.

Selection and Designation of an Archival Repository

Early in 1985 the committee began a search for a university medical library willing to house and preserve the documents and memorabilia of the Association, and qualified to do so. Overtures were made to several institutions, each of which expressed interest in the project. However, the most enthusiastic responses came from the University of Alabama at Birmingham, the city in which the Association had been founded in 1887.

The Lister Hill Library of the University of Alabama was completed by the State in 1971. The name of the library commemorates the contributions of two generations of a distinguished Alabama family to medicine and surgery in the United States.

Lister Hill was the son of Luther Leonidas Hill, Jr., a native Alabama physician and surgeon. Luther Hill graduated in medicine from New York University, after which he trained under the elder Gross in Philadelphia and then under Joseph Lister at King's College in London. In his presidential address to the Southern Surgical Association in 1974, David C. Sabiston, Jr.[1] of Durham states that "many contributions to cardiac surgery have their origin in this country, and the first major achievement in this field was made in 1902 by Luther Leonidas Hill, Jr. of Alabama." Sabiston goes on to say that in 1902 Luther Hill performed the first successful closure of a heart wound in this country, and gives details of the injury and operation. He then adds the following: "One cannot mention the name of Hill in the United States without recognizing its more recent pertinence in the field of medicine. Dr. Luther L. Hill's son, Lister, named for Joseph Lister, was first sent to the United States Congress from Alabama at the young age of 28 and was later elected to the United States Senate in 1938. He was the original author of the Hill-Burton Act for the building of hospitals, which, together with his strong support of medical research through the National Institutes of Health, has brought the United States to first place among the nations of the world in medicine. Lister Hill served in Congress for 45 years and was consistently a champion of medical education, research, and patient care."

In 1985, an extensive correspondence was begun with Dr. Arnold G. Diethelm, Chairman of the Department of Surgery at UAB with Dr. Charles A. McCallum, then Senior Vice President for Health Affairs and now President of the University, and with other Birmingham members of the Southern Surgical Association. At the invitation of Drs. Diethelm and McCallum, the committee chairman visited the university and the Lister Hill Library in March 1986.

The handsome library is attractively situated in the central area of the university campus. A statue of Lister Hill and his portrait are displayed prominently on the main floor. In the stacks there are two complete sets of the *Transactions of the Southern Surgical Association.* Two rooms on the upper floor are memorials to physicians who made enduring contributions to this institution and to medicine and surgery nationally and internationally. One of them was Tinsley Harrison, renowned educator in internal medicine. The other was Champ Lyons, active member of the Southern Surgical Association from 1945 until his death in 1965. The Champ Lyons Room is filled with his memorabilia and also contains a Moretti marble bust of W. E. B. Davis, Founder of the Southern Surgical Association.

In addition to its general reference section, the Lister Hill Library houses two important historical collections. One of these, the Reynolds Historical Library, contains rare medical, dental, and scientific texts, manuscripts, and letters accumulated by Dr. Lawrence Reynolds, a noted Alabama bibliophile, and which were given by him to the Medical Center in 1958. The other is the Alabama Museum of the Health Sciences, which contains instruments, photographs, documents, and other pieces of equipment significant in the history of medicine and related fields in Alabama. The desk and books of Luther Hill are displayed in the museum, and there is a large collection relating to J. Marion Sims. There are also individual biographical files on Luther and Lister

Hill, the Davis brothers, and many Alabama physicians, including those who became presidents of the Southern Surgical Association.

State supported institutions such as the University of Alabama, or any other university that falls in the same category, can encounter unexpected severe budgetary restrictions as a consequence of events such as the problems now besetting the oil industry or the Black Monday crisis in the stock market. The State of Texas educational system, for example, perhaps the most heavily endowed in the nation, is currently attempting to cope with substantial reductions in its operational funds. The University of Texas Libraries are obliged to share their part of the problem. Moreover, municipal libraries, such as those of Dallas or Houston, are similarly affected by the economic climate, and have been obliged to reduce their staffs and their acquisitions. When major budgetary restrictions are imposed on libraries, the divisions likely to suffer most are those devoted to the special collections, unless some specific provision has been made for their support. If the University of Alabama at Birmingham were confronted with unusual money problems, it is not to be expected that the Lister Hill Library would give a very high priority to the continuing needs of the Southern Surgical archives. It seemed prudent to the committee, therefore, to investigate the possibility of establishing within the university a permanent endowment fund, the income from which would be expended only for the preservation, maintenance, and utilization of the archival collection.

A plan to achieve this objective was developed as follows. Joseph M. Donald, a highly respected Birmingham surgeon and an active and devoted member of the Southern Surgical Association, was elected to its Presidency in December 1960, but died only 2 months later, on February 13, 1961, before he could serve his term. Joe Donald had made many enduring contributions to medicine and surgery, especially in his own State, and had a wealth of friends and admirers. A proposal was made to Dr. Diethelm that consideration be given to the establishment at UAB of a Joseph M. Donald Memorial Endowment Fund, the sole purpose of which would be to ensure in perpetuity the maintenance and utilization of the Southern Surgical Association historical collection.

Dr. Diethelm responded to this proposal by pledging that the UAB Department of Surgery would contribute $5,000.00 a year to the fund for a minimum of 3 years. The Council of the Southern Surgical Association approved the project and made an initial annual pledge of $1,000.00 to it. On June 17, 1987, the instrument of trust defining the purpose and conditions of the agreement was submitted by President McCallum to the Board of Trustees of the University. The approval of the Board, which was granted on that date, was the final step in establishing the Lister Hill Library as the official archival repository of the Southern Surgical Association.

An initial goal of $50,000.00 was announced in the document. In the 6 months between the announcement and the anniversary meeting of the Southern Surgical Association, this first plateau was reached in donations and pledges. Much of the credit for this gratifying response should be given to Joseph M. Donald, Jr., member of the Association since 1971, and to his wife and family, who have worked diligently to publicize the fund and to encourage contributions to it. Other Birmingham members of the Association have also participated in this effort. The second plateau of the goal for this endowment, but not the last one, will be $100,000.00.

The Southern Surgical Association owes an enduring debt of gratitude to Dr. Diethelm and President McCallum of the UAB and to the Birmingham members of the Association for their cooperation and influence in helping to establish a permanent home for the organizational archive in a location so well suited to this purpose.

The 100th Anniversary Meeting and the Century Ahead

In appreciation of the historic significance of the 100th anniversary meeting, arrangements were made on this occasion, for the first time, for professional videotaping of the opening ceremonies, the presidential address, the Monday morning and Wednesday morning symposia, and portions of the social events. Taping was done under the direction of Mr. Leo T. McGovern, Chief Executive Officer of Ciné-Med Inc., of Woodbury, Connecticut. One complete copy of the videotapes will become a part of the archival collection.

Special features of the opening ceremonies that will become important parts of the videotape collection include a prayer of invocation by Association member, the Reverend Raymond C. Ramage, M.D., and a videotaped message of greeting from the President of the United States, Ronald Reagan, and the First Lady. Before her marriage, Miss Nancy Davis had attended the 1948 meeting of the Association with her parents, Dr. and Mrs. Loyal Davis of Chicago. Dr. Davis had been an active member of the Association from 1933 until his death in 1982.

An additional special feature was the presentation to the Homestead Hotel by the Association of a bronze plaque commemorating the celebration of the 100th anniversary meeting, the 28th meeting of the Association to be held at the Homestead. The plaque was accepted formally by Mr. Daniel H. H. Ingalls, Jr., President of the hotel. It will be mounted on the front veranda in proximity to three commemorative plaques that are already there. Replicas of the plaque, each mounted on a 5 × 7-inch mahogany base, were presented to each member in attendance as a souvenir of the meeting, and will also become a part of the historical collection, along with the design drawings and rubbings of the plaque.

Throughout the anniversary meeting, an elaborate historical exhibit was on view in the South Terrace of the Homestead Hotel. Most of the items comprising the archival collection were displayed, along with special exhibit panels prepared by designated members from each of the Southern states. In 1988, the historical collection will be transferred to its new home in the Lister Hill Library at the University of Alabama in Birmingham.

During the centenary meeting a decision was made by the Council and approved by the membership of the Association to establish the office of Archivist, placing this responsibility on the treasurer, who is also the editor of the annual volume of *Transactions.* This wise decision affirms that as the Association embarks on its second century, its members have recognized the important place that its deliberations occupy in the corpus of surgical history in America, and ensures that the documentation of its proceedings and preservation of its archives will never be overlooked or neglected.

Important Risk Factors of Allograft Survival in Cadaveric Renal Transplantation

A Study of 426 Patients

ARNOLD G. DIETHELM, M.D., EUGENE H. BLACKSTONE, M.D., DAVID C. NAFTEL, PHD., SHARON L. HUDSON, M.B.A.,
WILLIAM H. BARBER, M.D., MARK H. DEIERHOI, M.D., BRUCE O. BARGER, PH.D.,
JOHN J. CURTIS, M.D., and ROBERT G. LUKE, M.D.

Multiple risk factors contribute to the allograft survival of patients who have cadaveric renal transplantation. A retrospective review of 19 such factors in 426 patients identified race, DR match, B + DR match, number of transplants, and preservation time to have a significant influence. The parametric analysis confirmed the effect to be primarily in the early phase, *i.e.*, first 6 months. All patients received cyclosporine with other methods of immunosuppression resulting in an overall 1-year graft survival rate of 66%. The overall 1-year graft survival rate in the white race was 73% and in the black race was 57% (p = 0.002). Allograft survival and DR match showed white recipients with a 1 DR match to have 75% survival at 1 year compared with 57% in the black patient (p = 0.009). If HLA B + DR match was considered, the white recipient allograft survival increased to 76%, 84%, and 88% for 1, 2, and 3 match kidneys by parametric analysis. Patients receiving first grafts had better graft survival (68%) than those undergoing retransplantation (58%) (p = 0.05). Organ preservation less than 12 hours influenced allograft survival with a 78% 1-year survival rate compared with 63% for kidneys with 12–18 hours of preservation. Despite the benefits of B + DR typing, short preservation time, and first transplants to the white recipient, the allograft survival in the black recipient remained uninfluenced by these parameters.

THE IMPROVEMENT IN the results of cadaveric renal transplantation since the advent of the cyclosporine era has been well supported by a number of multicenter and single center reports. The European multicenter trial[1,2] and the Canadian trial[3] reported 1-year allograft survival rates of 72% and 80%, respectively. Opelz[4] reported a 1-year survival rate of 76%, and recently Cicciarelli et al.[5] reviewed data from 3500 transplant patients receiving cadaveric kidneys showing a 75% allograft survival rate at 1 year. Kahan and colleagues[6] reported a 1-year survival rate of 245 cadaveric renal allografts to range from 77% to 85% depending on the method of cyclosporine administration. Despite these encouraging reports, the overall 1-year allograft survival rate in our experience with cyclosporine in various combinations with other drugs was 66% compared with our previous survival rate of 57% in patients receiving azathioprine and prednisone.

From the Departments of Surgery and Medicine (Nephrology), The University of Alabama School of Medicine, University Station, Birmingham, Alabama

The current study examines the important factors pertaining to allograft survival with special emphasis on the histocompatibility match, race, first and second transplants, duration of preservation, percent reactive antibody, and the presence of diabetes. This single center review has two important features in that all operations were performed by five surgeons and 95% of all kidneys were procured by one organ procurement center with preservation by cold storage using Eurocollins solution. The large number of black patients in this study (41%) allowed a unique opportunity to study the racial effect on graft survival.

Clinical Material and Methods

From December 1983 until January 1, 1986, 437 consecutive patients underwent cadaveric renal transplantation at the University of Alabama Medical Center. This study includes 426 of those patients excluding 11 children younger than 10 years. The immunosuppressive therapy in all patients included cyclosporine, prednisone, and other additional agents such as azathioprine, OKT3 monoclonal antibody, and rabbit antithymocyte globulin (RATG). The RATG was prepared in the Department of Surgery Transplantation Research

24	48 (47)	58 (78)	52 (39)	58 (38)	65 (1)

* p = NS.

Laboratory using 1 × 10^8 human thymocytes injected intravenously into rabbits on day 0, 14, and bleeding on day 21. A crude globulin was then prepared and 4 ml of RATG was administered intravenously for 4–7 days.

The three groups of patients include Group I, which comprised patients who received cyclosporine and prednisone (N = 80). The initial dosage after transplantation was 12-17 mg/kg/day of cyclosporine and 200 mg qd of prednisone. The cyclosporine was tapered to 7–10 mg/kg and the prednisone decreased to 30 mg qd at 30 days. Group II comprised patients who received cyclosporine, RATG, and prednisone (N = 84). The initial dosage of cyclosporine was 5 mg/kg/day, 4 ml/day of RATG for 4–7 days, and 100 mg/day of prednisone. The RATG was discontinued between the 4th and 7th posttransplant day at which time the cyclosporine was increased to 10–14 mg/kg/day and prednisone gradually decreased to 30 mg/day at 30 days after transplantation. Group III comprised patients who received cyclosporine, prednisone, and azathioprine (N = 262). The initial dosage was 5 mg/kg/day of cyclosporine, 2 mg/kg/day of prednisone, and 100 mg/day of azathioprine (see Table 1). The cyclosporine dosage was adjusted according to serum or blood levels and serum creatinine level. Measurements of trough levels included both serum and whole blood using radioimmunoassay (RIA, Sandoz Pharmaceuticals, East Hanover, NJ). The therapeutic range for serum cyclosporine was 100–250 ng/ml and for whole blood was 250–500 ng/ml. The prednisone dosage immediately after operation was gradually reduced to 30 mg/day at 1 month. In most patients the prednisone dosage at 6 months was 15 mg/day or less, and at 1 year was between 10 and 12.5 mg/day. In no patient was prednisone completely withdrawn. The azathioprine dosage of 100–125 mg/day remained constant except for reduction when the white blood count was less than 4,000/mm^3.

TABLE 2. *Renal Disease*

Diabetic	74 (17%)
Glomerulonephritis	93 (22%)
Vascular	91 (21%)
Interstitial	34 (8%)
Hereditary	54 (13%)
Collagen	8 (2%)
Acquired	5 (1%)
Other/Unknown	67 (16%)

The diagnosis of rejection was established by the clinical signs of graft enlargement, fever, and renal tenderness combined with the laboratory evidence of an increase in serum creatinine and blood urea nitrogen levels with evidence of rejection by renal scintigraphy including a decrease in the effective renal plasma flow. Allograft rejection was treated by an increase in oral steroids to 5 mg/kg/day with gradual reduction to 1.5 mg/kg/day 7 days later and to a level of 30 mg/day 10–14 days after the onset of rejection. One gram of intravenous methylprednisone was given daily for the first 3 days of the antirejection treatment. If rejection recurred it was treated a second time with three intravenous pulses of methylprednisone (1 g each) with or without an increase in oral steroids. No patients were treated more than twice for rejection.

OKT3 monoclonal antibody was used for the treatment of acute rejection. This was used instead of corticosteroids in some patients as the primary treatment of acute rejection and also in the management of those patients who failed to respond to steroid therapy as a means of rescue therapy. OKT3 treatment included a dosage of 5 mg/day intravenously for 10–14 days. During OKT3 administration, cyclosporine was reduced to 5 mg/kg or less and azathioprine decreased to 25 mg/day. Prednisone administration continued at 30 mg/day.

All kidneys, procured from heart beating cadavers, were preserved by cold storage using Eurocollins solution and removed from patients pronounced brain dead from the ages of 2–67 years. More than 95% of the kidneys were procured and preserved by the Alabama Regional Organ and Tissue Center and less than 5% were transported to this center from other programs. The age of the recipients ranged from 10 to 66 years with a mean age of 38 years (SD: 11 years). Two hundred and seventy-five patients (65%) were male and 151 patients (35%) were female. Two hundred and fifty-one (59%) were white and 175 were black (41%). The primary disease of the recipient patient is demonstrated in Table 2. The age distribution is depicted in Table 3. All operations were performed by five faculty surgeons of the Department of Surgery with the pre- and postoperative management by the transplant nephrologists and surgeons of the transplant service. All patients after hospital discharge were followed up in the renal transplant clinic in conjuction with the referring nephrologist. None of the 426 patients were lost to follow-up. The minimum follow-up for functioning allografts was 3 months, the maximum was 38 months with a mean graft time of function of 12.8 months (SD: 10.5 months).

The control group included the 100 patients receiving cadaveric kidneys before December 1983, preserved by Eurocollins solution. These patients received azathioprine and prednisone as immunosuppressive therapy and were analyzed for allograft survival 1 year after transplantation. The initial dosage of azathioprine was 100–150 mg qd with long-term maintenance at 100–125 mg qd. The initial prednisone dosage of 5 mg/kg/day was reduced to 30 mg/day at 1 month. Rejection was treated with three pulses of intravenous methylprednisone over 3 days frequently combined with an increase in oral prednisone.

In Groups I and II the cyclosporine dosage was given orally each morning in almost all patients and adjustments were made to maintain serum trough levels at 24 hours between 50 and 200 ng/ml. In Group III the same dosage schedule was maintained with whole blood levels between 250 and 500 ng/ml. Intravenous cyclosporine was rarely used except where oral intake was not possible. In such circumstances the intravenous dosage was one third of the oral dosage.

Histocompatibility matching with HLA typing was performed in all patients receiving cyclosporine. DR matching was completed in all but 22 patients. Those patients receiving azathioprine and prednisone in the control series had complete HLA typing but incomplete DR typing. Blank donor/recipient antigens were not counted as a match when calculating the number of matched HLA − A, B or DR antigens. Percent reactive antibody (PRA) levels were calculated from serum lymphocyte cytotoxicity assays against a 42-member sera-defined frozen sera panel. The final crossmatch between the patient and donor consisted of three separate assays, which included an Amos modified wash assay, a three wash procedure, and extended incubation crossmatch. Mixed lymphocytes were used in all assays. A B lymphocyte crossmatch was performed if the extended incubation indicated possible B cell antibodies.

After all data were verified, actuarial analysis of survival was accomplished by the Kaplan-Meier method,[7] with the Gehan-Wilcoxon[8] technique providing the p value for stratified curve comparison. A hazard function (the instantaneous risk in patients not yet experiencing graft loss) for loss as a time related event was determined by the parametric model of Blackstone, Naftel, and Turner.[9] The model identified an early (0–6 months) and constant phase (6 months +) and determined the incremental risk factors for graft loss for each phase. The constant phase begins at time zero. Its effect becomes relatively important after the early phase diminishes at about 6 months. Variables were considered important only if their p value was less than 0.06. All confidence limits were expressed as 70%. Graft loss was considered to be at the time of nephrectomy, return to dialysis or death if the graft was functioning. There were no exclusions for technical or nonimmunological failures.

TABLE 3. *Age in Years*

10–19	26 (6%)
20–29	72 (17%)
30–39	127 (30%)
40–49	148 (35%)
50–59	46 (11%)
60+	7 (1%)

Nineteen potential risk factors were examined in the parametric model including age, sex, race, total number of transplants, A match, B match, A + B match, DR match, B + DR match, peak PRA, current PRA, sensitized PRA if peak or current is greater than 10%, past positive but current negative (PPCN) PRA, previous transplant antigen mismatch, type of renal disease, donor race, donor sex, donor age, and total preservation time of the allograft. In addition, these risk factors were analyzed for possible interactions. An accurate history of previous blood transfusions was not available and therefore not included in the analysis. However, the policy of deliberate blood transfusions before transplantation as a means to induce a transfusion effect was discontinued before December 1983.

Results

Allograft Survival

The overall graft survival of all patients receiving various immunosuppressive protocols including cyclosporine was compared with the control group of patients receiving azathioprine and prednisone and revealed the 12-month graft survival rate of the control group to be 57% compared with 66% of the cyclosporine group (p = 0.08) (see Table 1). Three subgroups comprised 426 patients in the cyclosporine group. Group I (N = 80) included cyclosporine and prednisone. Group II (N = 84) included cyclosporine, prednisone, and RATG. Group III (N = 262) included cyclosporine, prednisone, and azathioprine. The 12-month graft survival rates of the three subgroups were 60%, 71%, and 67%, respectively (p = NS). The overall graft survival rate of patients receiving cyclosporine was 66% at 1 year, shown in Fig-

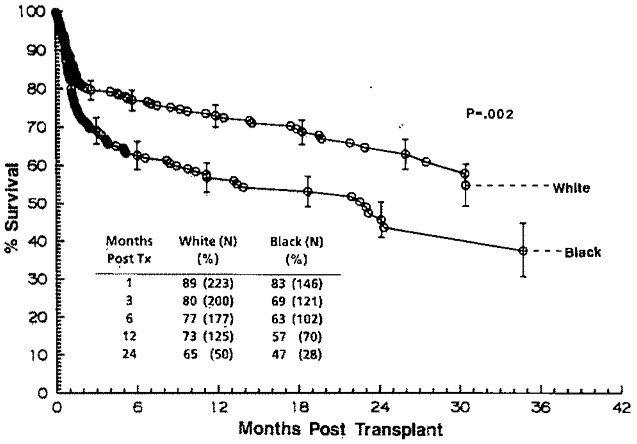
ure 1, decreased to 58% at 2 years (Kaplan-Meier). This survival curve compared closely with the projected survival by the parametric analysis (Fig. 1). The parametric analysis presented in Figure 2 emphasized the early high instantaneous hazard to allograft survival in the early phase (*i.e.*, the first 6 post-transplant months). This was followed by a remarkably low graft loss during the constant phase (the next 32 months).

The important risks determined by multivariate analysis of nineteen factors revealed five to be important (see Table 4). These were the recipient race, number of transplants performed, DR match, B + DR match, and organ preservation time. These risk factors had a significant and relevant effect on allograft survival.

The comparison of allograft survival in recipients of the black race (N = 175) versus those of the white race (N = 251) receiving cyclosporine, compared in Figure 3, showed the white recipient to have a 73% 1-year allograft survival rate versus the 57% survival rate of the black recipient (Kaplan-Meier) (p = 0.002). The parametric analysis in Figure 4 showed both races to have a high risk for allograft loss in the early phase. However, black patients have a risk of graft loss greater than white



Months Post Tx	White (N) (%)	Black (N) (%)
1	89 (223)	83 (146)
3	80 (200)	69 (121)
6	77 (177)	63 (102)
12	73 (125)	57 (70)
24	65 (50)	47 (28)

FIG. 3. Comparison of allograft survival between black and white recipients demonstrates improved allograft survival in white recipients (Kaplan-Meier).

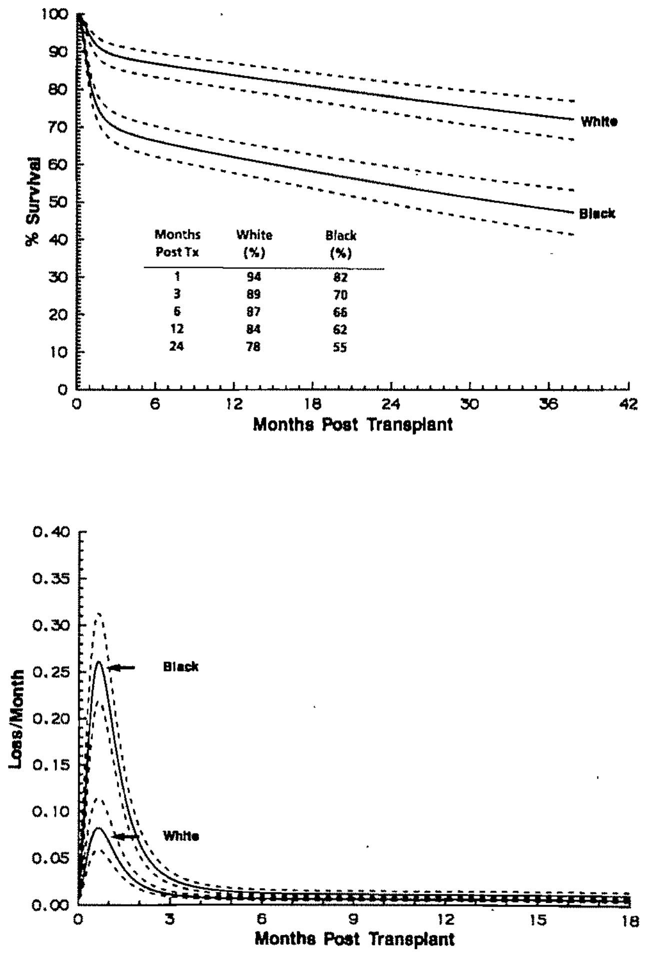


FIG. 4. The lower figure shows renal allograft loss in both races to occur in the early phase in the post-transplant course with the risk of allograft loss greater in blacks. The constant phase from 6 to 18 months shows blacks to continue to have a greater allograft loss. The upper figure compares renal allograft survival in the two races. For both figures, the equation was solved for: total number of tx = 1, for whites B + DR = 2, peak PRA = 0, ischemic preservation time = 12 hours (parametric).

recipients in both the early and constant phase. The racial origin of the donor kidney had no significant effect on allograft survival. (White donor to white recipient [N = 232] *vs.* black donor to white recipients [N = 19] or white donor to black recipient [N = 148] *vs.* black donor to black recipient [N = 27].)

Allograft Survival and DR Match

Allograft survival in all patients with 0, 1, and 2 DR matches are compared in Table 5. At 1 year, patients with a zero DR match had a 63% graft survival rate (N = 225), a one DR match had a 68% graft survival rate (N = 165), and a two DR match had an 84% graft survival rate (N = 14). Separation of the patients by race and DR match showed the white recipients to have a 75% survival rate at 1 year compared with a 57% survival rate in the black recipient patients receiving a one DR match graft (p > 0.009) (Fig. 5) (Kaplan-Meier).

TABLE 5. *Allograft Survival and DR Match*

Months After Operation	0 DR % N	1 DR % N	2 DR % N
0	100 (225)	100 (165)	100 (14)
3	71 (160)	78 (128)	93 (13)
6	67 (136)	74 (112)	93 (13)
12	63 (91)	68 (82)	84 (7)
24	51 (36)	64 (29)	84 (1)

0 DR vs. 1 DR p = 0.09
0 DR vs. 2 DR p = 0.04
1 DR vs. 2 DR p = 0.12

Allograft Survival and HLA B + DR Match

When HLA B match and DR match were combined (B + DR), important differences were noted in overall allograft survival between the 0, 1, 2, and 3 matched kidneys. The 0 match kidney had a 58% 1-year survival rate compared with 70%, 73%, and 82% survival rates for 1, 2, and 3 B + DR matched grafts (p = 0.03, 0.009 and 0.06, respectively) (see Table 6). The parametric analysis depicted in Figure 6 showed the risk of early graft loss confirming the beneficial effects of B + DR typing in white recipients similar to that noted in the Kaplan-Meier analysis of Figure 5. Black patients exhibited the same allograft survival regardless of the B + DR matching.

Allograft Survival, B + DR Match and Racial Consideration

If racial influence was considered with the B + DR match, an important difference was noted in the para-

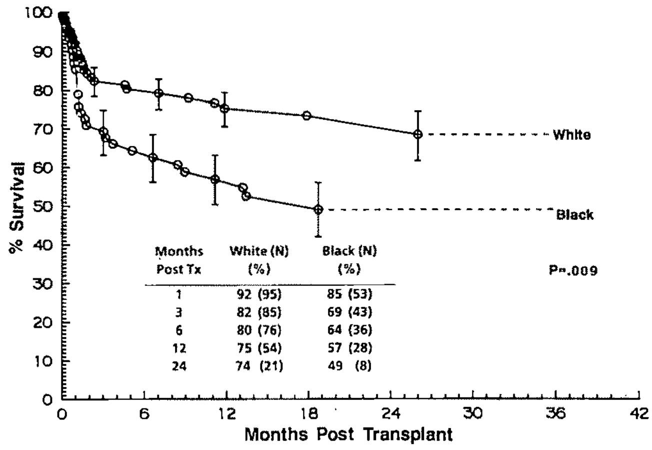

FIG. 5. Allograft survival in black and white patients with a 1 DR match shows the white patients to have a 75% 1-year graft function compared with 57% in the black recipient (p = 0.009) (Kaplan-Meier).

TABLE 6. *Allograft Survival and B + DR Match*

Months After Operation	0 B + DR	1 B + DR	2 B + DR	3 B + DR
0	100 (160)	100 (166)	100 (63)	100 (14)
3	67 (107)	78 (129)	82 (52)	93 (13)
6	63 (88)	73 (113)	82 (47)	93 (13)
12	58 (54)	70 (85)	73 (34)	82 (7)
24	52 (25)	56 (27)	69 (12)	82 (2)

0 B + DR vs. 1 B + DR p = 0.03
0 B + DR vs. 2 B + DR p = 0.009
0 B + DR vs. 3 + 4 B + DR p = 0.06
1 B + DR vs. 2 B + DR p = 0.28
1 B + DR vs. 3 + 4 B + DR p = 0.26
2 B + DR vs. 3 + 4 B + DR p = 0.60

metric analysis of overall allograft survival between white and black patients (p = 0.003) (Fig. 7). There was no difference in the 3-month allograft loss between black recipients and white recipients with a 0 B + DR match. However, a significant difference was observed in white recipients of a 1 and 2 B + DR match (p = 0.02, p = 0.01, respectively). The allograft hazard loss is depicted by the parametric analysis in Figure 6. Black recipients were at greater risk for allograft loss not only in the early phase (first 6 months after transplantation) but continued throughout the constant phase (32-month follow-up period) (p = 0.05). Figure 6 showed the hazard of allograft loss to exist in the early phase in both races, but the persistent loss was greater in the constant phase of black patients. The individuals at lowest risk in the early phase were those white patients receiving allografts with well-matched B + DR kidneys.

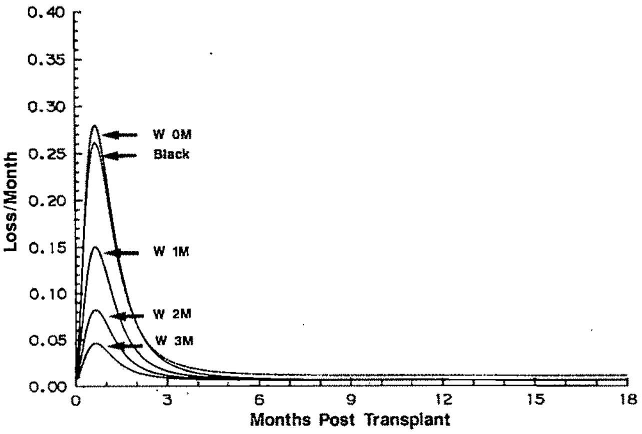

FIG. 6. The hazard of allograft loss in the early and late phases by B + DR match and race shown above, emphasizes the greatest risk of loss to be in the early phase (first 6 months) with little difference in the constant phase (6–18 months). The equation was solved for: total number of tx = 1, total preservation time = 12 hours, peak PRA = 0 (parametric).

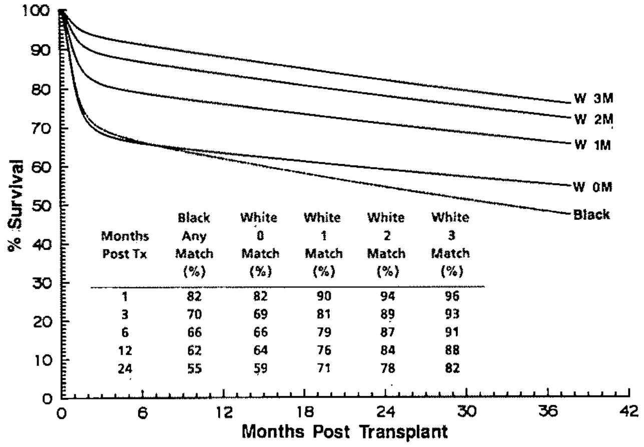


Months Post Tx	Black Any Match (%)	White 0 Match (%)	White 1 Match (%)	White 2 Match (%)	White 3 Match (%)
1	82	82	90	94	96
3	70	69	81	89	93
6	66	66	79	87	91
12	62	64	76	84	88
24	55	59	71	78	82

FIG. 7. The effect of combining B + DR match by race, demonstrated above, shows the white patient with the best matched kidneys to have improved allograft survival to the 0 match white recipient or any black recipient regardless of match. The equation was solved for: total number of tx = 1, ischemic preservation time = 12 hours, peak PRA = 0 (parametric).

Allograft Survival in Primary and Retransplantation with Racial and B + DR Consideration

Three hundred and seventy-one patients received first allografts with a 68% 1-year graft survival rate compared with a 58% 1-year graft survival rate of 55 patients undergoing retransplantation (p = 0.05). If the racial influence is taken into consideration in regards to first and second kidney transplants, the white recipient of a first transplant regardless of match (N = 213) had a 76% 1-year graft survival rate compared with a 59% 1-year graft survival rate in a white patient receiving a second or third kidney (N = 38) (p = 0.02). However, in the black recipient with a first transplant (N = 158), there was no significant difference in the allograft survival rate in the first year (57%) compared with the black recipient of subsequent transplants (59%) (N = 17). White patients receiving first transplants (N = 125) had an allograft survival rate of 82% at 1 year in both 1 and 2 B + DR matched groups compared with a 65% survival rate in the 0 B + DR match (N = 66) (p = 0.02 and 0.006, respectively).

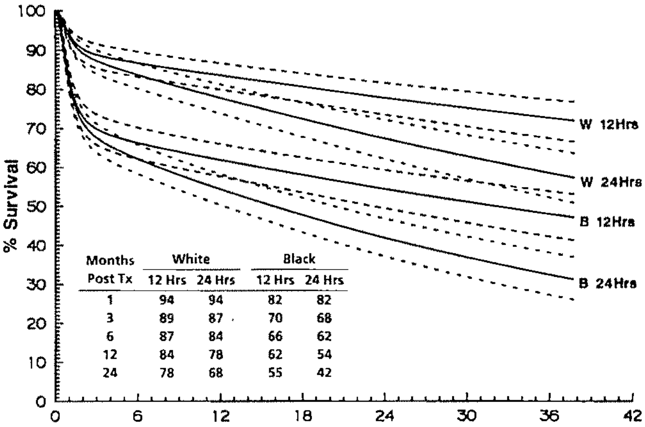
Allograft Survival and Duration of Preservation

Recipients of kidneys (both blacks and whites) preserved by Eurocollins cold storage for less than 12 hours

TABLE 7. *Risk Factors Kaplan-Meier*

Cyclosporine improves graft survival	(p = 0.08)
Primary transplants have better survival	(p = 0.05)
Survival better in white race	(p = 0.002)
B + DR important in white race	(p = 0.02)
Preservation time 12 hours or less	(p = 0.04)

(N = 52) had a 78% 1-year graft survival rate compared with 63% for kidneys preserved 12–18 hours (N = 176) (p = 0.04). Figure 8 predicted the effects of 12 and 24 hours of preservation time on graft survival by parametric analysis emphasizing the improved allograft survival in those patients receiving kidneys preserved for 12 hours or less. Again the racial influence was noted with the black recipients having less favorable survival. Figure 9 showed the allograft loss to be predominantly in the early phase (first 6 months) in both races. Although the allograft survival in the two races was different, the influence of the ischemic interval became increasingly important in the constant phase (p = 0.015). The overall incidence of renal dysfunction after transplantation requiring dialysis in the cyclosporine-treated recipients was 31%. Permanent nonfunction of kidneys after transplantation was 4%.



Months Post Tx	White 12 Hrs	White 24 Hrs	Black 12 Hrs	Black 24 Hrs
1	94	94	82	82
3	89	87	70	68
6	87	84	66	62
12	84	78	62	54
24	78	68	55	42

FIG. 8. A comparison of the preservation interval and allograft survival in blacks and whites is depicted above showing 12 or 24 hours of preservation time in white recipients has a better prognosis for long-term kidney function than black recipients. The equation was solved for: total number of tx = 1, B + DR match = 2, peak PRA = 0 (parametric).

Allograft Survival and the Effect of Percent Reactive Antibody

In the absence of percent reactive antibody, a primary transplant (N = 321) had better graft survival than a retransplant (N = 23) (p = 0.002). This relationship remains consistent if the antibody titer was greater than zero, with patients receiving first kidneys having a 70% 1-year graft survival rate compared with a 56% survival rate (N = 32) if they had one or more previous transplants (p = 0.05).

Allograft Survival and Primary Disease

There was no relationship between the primary renal disease and allograft survival. Because of the increasing number of patients with diabetes, this group was examined. Seventy-four patients with diabetes had a 77% 1-year graft survival rate compared with a 64% graft survival rate in the nondiabetic patient (p = NS). However, when racial influence was considered there was improvement for white nondiabetic recipients (N = 194) as compared with the black recipient patient group (N = 158) (71% *vs.* 56%, respectively) (p = 0.01). When the diabetic black (N = 17) or white (N = 57) patients were compared, there was no significant difference between the two groups. (Note: the N for the black diabetic patient was only 5 at 1 year follow-up compared with 31 in the white diabetic patient).

Mortality

Thirty-five of the 426 patients died within 0–38 months after transplantation. Patients who died with functioning grafts or who died within 3 months of graft failure while on dialysis were included as a mortality. Twenty deaths occurred within the first 3 post-transplant months and 6 occurred between the fourth and twelfth post-transplant month for a 1-year mortality rate of 6%. There were nine deaths after the first year for an overall mortality rate of 8%. Eighteen deaths occurred in white recipients and 17 occurred in black recipients. Twenty-three deaths were in male patients and 12 were in female patients. Twenty-one patients died with functioning kidneys and 14 patients died with nonfunctioning kidneys. Fifteen deaths occurred in patients with diabetes, seven of whom had Type I diabetes. The most common cause of death was infection (10 patients), cardiac (5 patients), CVA (4 patients), gastrointestinal bleeding (4 patients), liver failure (3 patients), pancreatitis (3 patients), carcinoma (1 patient), sickle cell disease

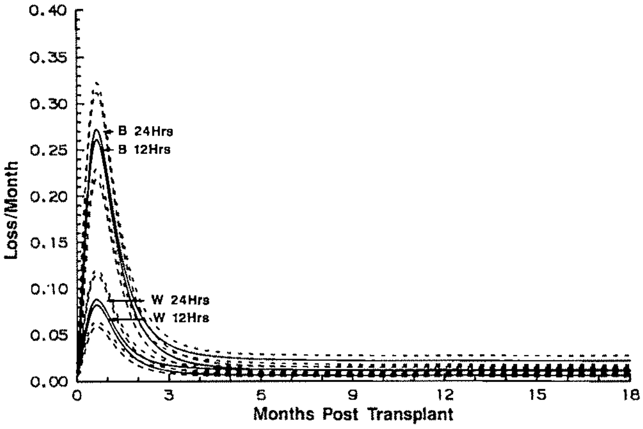


FIG. 9. A comparison of the preservation interval and allograft loss in blacks and whites shows both races to have the greatest risk for graft loss to be in the early phase. The black recipient not only has a greater risk of allograft loss in the early phase, but this continues in the constant phase. The equation was solved for: total number of tx = 1, B + DR match = 2, peak PRA = 0 (parametric).

(1 patient), suicide (1 patient), aortic thrombosis (1 patient), and unknown causes (2 patients).

Discussion

Multiple factors relating to patient death, technical considerations pertaining to nonimmunological causes for allograft loss, and the immunologic events leading to rejection of the kidney play important roles in the success or failure of long-term survival of the transplanted organ (Table 7). The Kaplan-Meier nonparametric analysis (Fig. 1A) demonstrates graft loss in this series of 426 patients to occur most rapidly in the first 3 months after transplant and then to assume a slowly declining graft survival during the next 32 months. The use of a parametric system allows the opportunity to construct a model of time-related distribution of events with specific risk factors for the early, constant, or late phase (Fig. 1B). Thus, the hazard function, *i.e.*, risk of graft loss—for whatever cause—is a time-related event that is influenced by multiple factors. The parametric analysis in Figure 2 shows the graft loss to be greatest in the early phase (6 months) with minimal loss in the constant phase (from 6 to 38 months). If, however, the patients were followed for 20 years, a late phase of graft loss would occur as a result of chronic rejection, which would then progress to renal failure. Blackstone et al.[9] reported a parametric system that allowed the modeling of time-related distribution of those events pertaining to the risk factors of death and other time-related events (graft loss) based on the decomposition of time varying risk factors into a small number of phases. Certain events are specific for each phase (*i.e.*, acute rejection—early phase and chronic rejection for the constant or late phase). Therefore, the hazard or risk function, survivorship function, and probability estimates with confidence limits (70%) are shown using the parametric model (Figs. 1B and 2). This model allows one to examine the relation between risk factors involving graft loss and time-related events, which allows the physician or surgeon involved in patient care the opportunity to develop useful inferences and project the probability of graft survival. This concept is of particular importance in allowing a given transplant program to examine the so called "center effect" as it pertains to the results of allograft survival and allows one to dissect the relevant and significant factors.

A comparison of the parametric model with the Kaplan-Meier graft shown in Figures 1A and 1B confirmed the two curves to be similar. The parametric model of Figure 2 emphasizes the hazard of allograft loss to be greatest in the early phase (first 6 months) followed by a constant phase.

The importance of HLA A and B typing in selecting recipients for cadaveric kidneys has long been a subject of dispute regarding its value in improving allograft survival when recipient patients are treated with azathioprine and prednisone. In 1981, McDonald et al. published a prospective multicenter study of 942 cadaver first allografts which showed HLA A and B typing to be important factors in both early and late allograft survival.[10] Subsequently, data from a similar prospective study[11] of 3811 cadaveric allografts evaluated the impact of HLA A and B typing and also showed allograft to be better in recipients of matched kidneys at 6 months and 4 years after transplantation. The importance of DR typing also has been documented to be of benefit in prolonging graft survival, especially in patients with 2 DR matches.[4,12] Opelz emphasized the beneficial effects of DR typing with cyclosporine as compared with the precyclosporine era.

The effect of HLA A and B matching combined with DR matching on kidney allograft survival in patients treated with or without cyclosporine has also been a matter of controversy. In 1985, Opelz[4] reported for the Collaborative Transplant Study on 2198 recipients receiving first cadaver kidneys to have a 76% 1-year graft survival rate with cyclosporine. This survival rate improved when HLA B + DR matching was combined, and if the recipients had 0 HLA B + DR mismatches, the allograft survival rate increased to 86%. Thus, combining cyclosporine and a kidney with 0, 1, or 2 HLA B + DR mismatches resulted in better allograft survival. These results were similar to those reported by Cicciarelli et al.[5] Both studies support the improved allograft survival noted in this series where recipients of B + 1 or 2 DR matched kidneys had a 73% and 82% survival rate, respectively (see Table 6). Therefore, optimum results appear to occur with the combination of a well-matched HLA B + DR matched kidney and the use of cyclosporine. It is important to emphasize the importance of the combined effect of HLA B + DR matching as opposed to HLA A and B or HLA DR alone. The obvious disadvantages of selecting patients according to tissue typing alone pertain to the large pool of recipient patients needed and the inherent problems of organ sharing and preservation. If, however, all of such factors could be controlled, then the effect of matching with current immunosuppressive drugs becomes important in obtaining optimal results in transplantation.

The effect of race on early and late allograft survival was not apparent in the precyclosporine data analysis from this center when both races had similar results at 1 year.[13] The early reports[14,15] suggesting that blacks had a less favorable allograft survival were reported at a time that DR typing was incomplete. In this report, white patients at 24 months had an allograft survival rate of 65% compared with the 47% rate in the black patients ($p = 0.002$) (see Fig. 3). This discrepancy increased when the cadaveric kidneys were matched with 1 DR grafts ($p = 0.009$), in which case the white recipients had a 7?%

1-year graft survival rate and a 2-year survival rate of 74% compared with 57% and 49% in the black recipients (see Fig. 5). The parametric analysis further elaborates on the effect in Figure 7 showing two and three match kidneys in white recipients to have an 84% and 38% 1-year graft survival rate, respectively (see Fig. 7). Opelz et al. in 1977[14] reported for the first time the apparent negative influence of the black race on allograft survival. This observation raised the important question of whether or not race-specific histocompatibility antigens exist, which might account for the less favorable allograft survival in black patients. The current report supports the observation that black patients have a less favorable graft survival. Black patients and white patients with a 0 match kidney have similar graft survival. However, when kidneys are matched for B + DR in both races, the white recipient has an improved graft survival. Therefore, the positive benefit of tissue typing in white recipients was not apparent in black recipients. The hazards of allograft loss due to acute rejection are especially visible in both races in the early phase (see Fig. 4) and the hazard of graft loss remains greater in the constant phase for the black recipient (see Fig. 4). This suggests that if racial antigenic differences are present, their effects in precipitating graft rejection are a greater risk in the early phase. If the allograft is not subjected to early loss in the black recipient, then the hazards of graft loss in the constant phase remain greater than for the white recipient. The reasons for failure of B + DR matching to improve allograft survival in the black race remain unclear. However, because the effect is most obvious in the early phase, noncompliance or socioeconomic factors are an unlikely cause. Unfortunately, the improved results reported by others of allograft survival in blacks treated with cyclosporine were not confirmed by this report.[16]

There is general agreement that primary or first renal transplants have a better prognosis than second or subsequent allografts.[17] This is particulary important in that the cyclosporine benefit to first graft recipients is not apparent in those patients receiving second or third kidney transplants. This observation was also supported by this study where the overall primary kidney transplant survival rate was 68% compared with a retransplant survival rate of 58% (p = 00.05). This comparison was accentuated in the white patient where the allograft survival rate after primary renal transplantation is increased to 76% (p = 0.02). The black recipient did not show improved allograft survival with the first kidney and maintained a 59% graft survival rate with retransplantation. This is in contrast to the white recipient of a first kidney with a one or two B + DR match where an 82% 1-year graft survival rate occurred. Unfortunately, the black recipient did not share the advantage of a primary kidney with a B + DR match. These results suggest that particular efforts must be directed to the regraft patient in regards to the selection of the donor kidney, to the previous antigens mismatched, duration of preservation, the degree of sensitization, and past positive, current negative cytotoxic antibodies.

There was no obvious effect of the primary renal disease on allograft survival. The hazards of diabetes surprisingly did not appear to be a factor in allograft survival in either the early or constant phase. However, the racial influence was persistent and the white diabetic recipient continued to show improved allograft survival compared to the black patient with diabetes. The importance of pre-existing percent reactive antibody in regards to allograft survival is unclear when the final crossmatch is negative. Some reports have suggested that patients with a high reactive antibody titer have less favorable survival.[18] The results from this study indicate that those individuals with peak antibody titers greater than zero could have better graft survival than those receiving previous transplants. Thus, preoperative sensitization did not seem to have an adverse impact on long-term graft survival if the preoperative crossmatch was negative. It is accepted, however, that early postoperative renal dysfunction may be due to immunologic factors such as subclinically detectable antibody titers, which may be responsible for accelerated type of rejections.[19] This study did not examine this question in greater detail than the allograft survival in relation to antibody titer.

DISCUSSION

DR. JOHN C. MCDONALD (Shreveport, Louisiana): This is a careful and important presentation from the University of Alabama cadaver renal transplantation. It makes several important points that are quite significant, and I commend Dr. Diethelm and his associates for this scholarly work.

Because of limited time, my comments are directed to one issue, which is the importance of tissue matching.

Under Dr. Diethelm's leadership, the University of Alabama's renal transplant program has become the second or third busiest such program in the nation. They perform about 150 grafts per year, which places them somewhat behind the University of California at San Francisco and about even with the University of Minnesota and the University of Pittsburgh, and certainly makes them the highest volume center in the South.

I have observed that all high volume centers have certain common characteristics. They have an enormous patient waiting list. They have a highly effective organ procurement program. They are generally committed to the concept that short preservation times are more influential in the outcome than tissue matching.

These characteristics lead them to perform many transplants that are poorly matched and very few that are well matched. Thus, when they analyze data, they generally see little influence of matching because they have what is really an insignificant number of well matched grafts.

I was quite surprised to see a significant influence of matching in this series, since there are only 14 reasonably well matched patients in the series of 403. It is clearly not unexpected that no relationship between matching and outcome was observed in the 175 black recipients, since there could have been only a handful of reasonably matched patients in this group.

Therefore, while it is perfectly correct to say that a black patient receiving a totally mismatched graft has a smaller chance of success than a Caucasian patient receiving such a graft, and similarly, that a one antigen matched graft is more likely to fail in a black patient than in a Caucasian patient, it is not possible to make a statement regarding the importance of matching in the black group from the data provided.

I would appreciate hearing from Dr. Diethelm's discussion of this issue and would pose two further questions:

Why did he not consider the A locus in his analysis, since most students of the field attribute a similar influence to the A, B, and D-R loci, and finally, has his finding of a favorable effect of matching in this highly mismatched group of patients led him to modify his clinical protocols regarding matching?

DR. ROBERT E. RICHIE (Nashville, Tennessee): I would like to congratulate the authors for bringing to us a superb analysis of the numerous variables which are involved in the success or failure of the renal allograft.

During the last two decades we have seen the one-year cadaver allograft survival improve from 45% to the present level of 85 to 90%. In my opinion, the strength of this paper lies in the complexity with which these many variables were examined.

Historically, small clusters of variables have been analyzed and may not, in fact, have given us the scope that we needed.

Another major contribution of this paper is the vast experience with transplantation in the black population. At our institution we have seen our 1-year functional graft survival improve from 68% in 1984, (at a time when only a few patients received cyclosporine, namely, those patients who could afford it), to 89% this past year when every patient received cyclosporine.

During the same time, the one-year patient mortality dropped from 5.2% in 1984 to 1.3% in 1986.

I am envious of Dr. Diethelm. He reports that greater than 90% of the cadaver kidneys transplanted are locally procured. In our program, 50% of the cadaver transplants are procured from other centers.

Local procurement has the usual advantage of decreased preservation time and better quality assurance. Dr. Diethelm did not mention acute tubular necrosis in his study. I would like to have him comment on the incidence of this and the implications relative to the time when cyclosporine was started.

The other point I would like to have him comment on is: Does he feel that the use of cyclosporine overcomes the so-called transfusion effect, since his manuscript states they no longer deliberately transfuse patients prior to transplantation?

DR. JOHN D. WHELCHEL (Atlanta, Georgia): I, too, would like to take this opportunity to compliment Dr. Diethelm and his colleagues on the excellent piece of work in this paper.

For years, we in the South have been looking at the results coming out of the Northwest that we couldn't reduplicate, and we always wondered why. Maybe we thought we were a little inferior. But I think Dr. Diethelm's work today gives us a good idea of some of the factors that may relate to the discrepancy we see coming from the Northwest and Midwest compared to things that we have been able to accomplish in the South.

I would like to ask Dr. Diethelm to comment on the fact that in most of the situations in transplant programs, we see that the results of living-related donor transplants in the black and white population is very similar, if not identical. Why then do we see this discrepancy in the cadaveric list and the cadaveric recipient?

I personally think it has a lot more to do with typing, but I would like Dr. Diethelm's own experience and his thoughts concerning this problem.

DR. THOMAS PETERS (Memphis, Tennessee): (Slide) Dr. Diethelm, your nicely presented data are of great interest and relate to important aspects of organ procurement and use across the country today.

The Southeastern Organ Procurement Foundation (SEOPF) data base has recently been examined regarding the same questions that you raise.

In a series of 3798 cadaveric kidney transplants from 52 SEOPF institutions, similar risk factors to the 27 studied at the University of Alabama were reviewed. Interestingly, 1411 kidneys came from multiorgan donors, while 2387 were from kidney-only donors. We also used univariate and multivariate techniques to determine early and late risks to allograft function.

We found, first, that multiorgan donation did not influence outcome for the kidney allograft recipient. In agreement with data in your abstract, we found that risk to graft was significant with the patient receiving a second or subsequent transplant. Also, peak panel reactive antibody greater than 60%, poor match at the HLA-AB and DR loci, as well as delayed graft function adversely influenced outcome. In these points, SEOPF data agrees with that from Birmingham. We also found that recipient race (white) was significantly favorable to outcome and that recipient age did not relate to outcome.

Of particular note, sharing *per se*, or shipment of kidneys had no effect on graft outcome, early or late.

My question, then, relates to the data regarding risks to graft loss in your study, confirmed by multicenter SEOPF data: What can the transplant surgical community do to limit these risks? It seems that organ-sharing based upon matching, especially for the multiply transplanted or sensitized recipient, would be helpful. Do you think that organ-sharing based upon immunologic criteria should, therefore, be expanded?

DR. A. G. DIETHELM (Closing Discussion): I would like to thank Dr. McDonald, Dr. Richie, Dr. Whelchel and Dr. Peters for their comments.

Dr. McDonald raised the important question that we had very few well matched patients of the black race, and it might be difficult to draw a conclusion from these few numbers. That is true, and it is also part of the dilemma. It is very difficult to obtain a good match in the black recipient. I will come back to that in a minute.

Concerning the question of the A locus: We did look at that question, but we found that the B plus DR-locus gave us the best benefit. This is not a unique observation with us. Dr. Terasaki's group has published that same observation some two years ago.

As regards the question of whether or not it will change our patient selection: It has, and I think that there are two observations that I would like to mention that are important at the present time. One is that we were clearly limited with cold storage hypothermic preservation, and we had a 28% dialysis requirement with an average cold storage time of 17 hours.

We switched to the Belzer perfusate and used pump perfusion, and now we have an average of a 30-hour ischemic preservation time with a 2% dialysis requirement for ATN. This particular change has made an important difference and will be important in the future in the selection of patients according to typing.

In our institution, it would not be possible to achieve better results by improved typing with the current limitations of the cold storage Eurocollins solution.

Dr. Belzer has a new solution that will be started in the multicenter trial and might be even more beneficial than the current techniques.

Dr. Richie asked about the incidence of ATN. I just mentioned that 28% of patients with an average preservation time of cold storage for 17 hours with Eurocollins solution did have important ATN.

We have tried a number of protocols with cyclosporine in this study. The best protocol was to start with either 5 mgs per kg per day of cyclosporine or less. We combine this with some form of antithymocyte globulin or OKT3 monoclonal antibody and do not increase the cyclosporine until the serum creatinine is 3 mgs or less.

The question of cyclosporine and blood transfusions poses some difficulties. It has been known for a number of years that patients receiving multiple transfusions have better cadaveric graft survival. The combined effect of cyclosporine and blood transfusion in our experience is minimal. I think one would have to look at Opelz's data from Europe, and there may be a positive effect with transfusions when combined with cyclosporine.

Dr. Whelchel asked the question of what can be done to better look at the antigenic profile of black patients.

First of all, we do need to have better techniques so that we can type for all antigens. At the present time we often have one, two or three antigens correctly typed in the black race, so, obviously, accurate tissue typing is not possible. This will require not only increased effort and time, but new techniques.

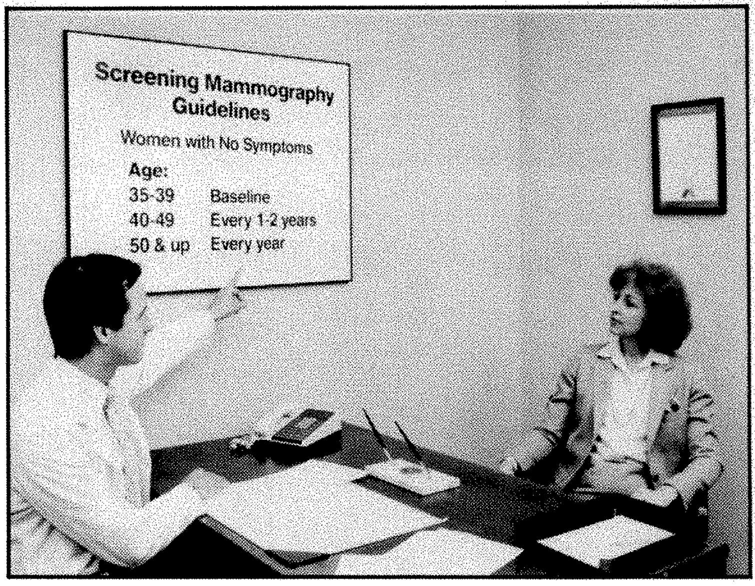
Dr. Peters asked what could be done to improve organ sharing and whether I believe that organ sharing should be carried out on an immunologic basis regarding the best match available.

I do believe that the data we have seen today and the information that has been published by Dr. John McDonald from SEOPF as well as information from Dr. Paul Terasaki in California all suggest that better matched patients may do better in the long run regarding graft survival. This is assuming that certain variables remain constant, and the most important variables that pertain to graft survival are those that occur in the first three months.

The best and most effective immunosuppressive therapy must be utilized. Yet there will still be certain patients, particularly those who are black, who proceed to reject their kidneys, despite maximal available immunosuppressive therapy. So in response to Dr. Peters, I will say that I am certainly not opposed to organ sharing as long as the important variable of organ ischemia is acceptable. We have to limit the duration of preservation to that time which is appropriate with organ viability and prompt function.

Last comment: For a number of years there has been a great deal of discussion about the center effect in transplantation. This is probably the same in all of surgery. Some hospitals, some surgeons and some transplant centers have better results, whereas others have less good results. This study, however, was the first opportunity we have had to use the parametric model to investigate the important variables that contribute to the results in our center. I am particularly grateful to Dr. Eugene Blackstone and his colleagues for helping us with that model.

What will you tell her about screening mammography?



Many of your patients will hear about screening mammography through a program launched by the American Cancer Society and the American College of Radiology, and they may come to you with questions. What will you tell them?

We hope you'll encourage them to have a screening mammogram, because that, along with your regular breast examinations and their monthly self examinations, offers the best chance of early detection of breast cancer, a disease which will strike one woman in 10.

If you have questions about breast cancer detection for asymptomatic women, please contact us.

TRANS-PLANT International

Official Journal of the European Society for Organ Transplantation

Editor-in-Chief: **Gauka Koostra, M.D.;** Department of Surgery, University Hospital, The Netherlands

The aim of this new journal is to serve as a forum for the exchange of scientific information in the form of original and high quality papers in the field of transplantation. Clinical and experimental studies, as well as editorials, letters to the editor, and occasionally, reviews on the biology, physiology and immunology of transplantation of tissues and organs, are published. Both full-length articles and short papers are presented in the journal. Papers submitted to the journal are subject to peer review.

(518) 674-3109

Made of #18 French biocompatable silicone for minimum trauma without sacrificing efficiency of performance.

* Send for reprints documenting results from independent clinical centers.

INCOMPARABLE MOSS®TUBES ....

(but compare with other feeding-decompression tubes anyway.)

1. Decompression Site

Gastric suction alone cannot work! The stomach's longitudinal folds mimic parallel segments of intestine. Aspiration orifices may empty a single "Magenstrasse" (figure A). Most swallowed air avoids suction, and is propelled through the pylorus via adjacent channels. A clinical study of other N-G and G-tubes measured 32-42% inefficiency. *A toll booth in the center of a wide highway cannot collect from traffic in the outer lanes.*
Removal of air is most effective at constricted (single-file) sites. Measured efficiency increases 12-fold by adding aspiration within the adjacent esophagus and/or duodenum. And flowing duodenal digestive juices "self-cleanse" the tube of occluding mucus.

2. Feeding site

Gastric feeding risks distention and aspiration. **Jejunal** delivery bypasses 1-3 feet of proximal intestine, acting as a barrier to retrograde decompression. Aspiration of feedings is less likely, but remains a risk. Minimal initial infusion (starvation) is manditory initially.

The **Moss®G-Tube's duodenal** delivery site is the most effective. With proximal duodenal aspiration (patented), the initial distal feeding rate is unlimited. Clinical x-rays visualized removal of all excess feeding, with none reaching the stomach. (Fig. B) The full length of intestinal absorption is available immediately. Earliest "enteral hyperalimentation" is safely instituted within the recovery room. Positive nutritional balances are achieved, leading to enhanced sepsis resistance, accelerated wound healing and shorter L.O.S.

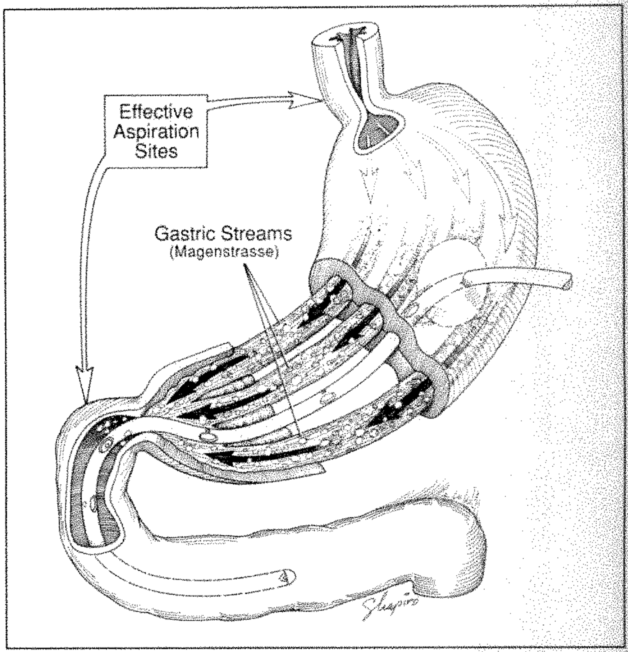
3. Aspiration Orifices

Uniformly sized orifices (**all others**) "suck in" mucosa to occlude the openings and stop decompression. Mucosal release then requires a null period (intermittant suction). Prograde air or retrograde feedings can be propelled accross and beyond the stomach, causing distention or aspiration.

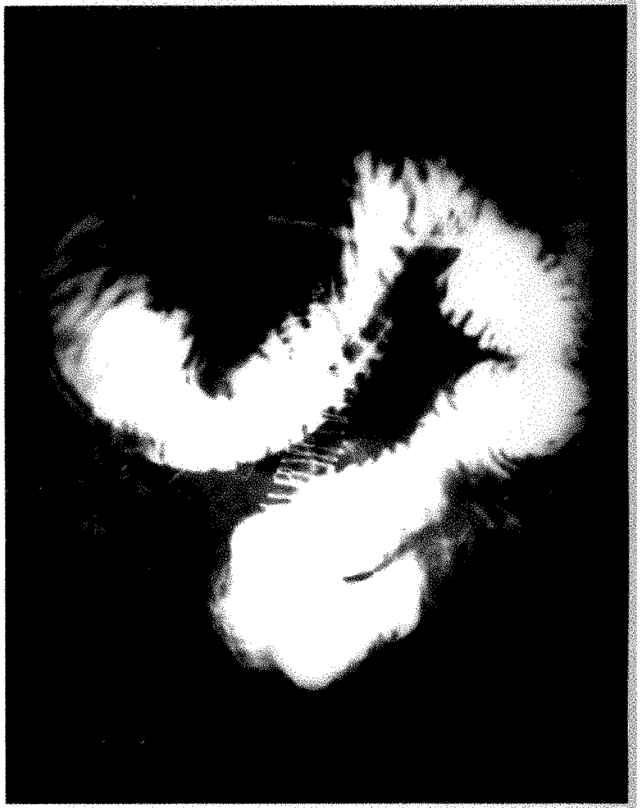
By pairing each large orifice with a patented, smaller "suction buster"®opening (**Moss®G-tube**), continuous aspiration is maintained despite inadvertantly elevated suction.

4. Biomaterials

The **Moss®G-Tube** is **all silicone**, the accepted "gold standard" for optimum long term stability, tissue tolerance and biocompatibility.

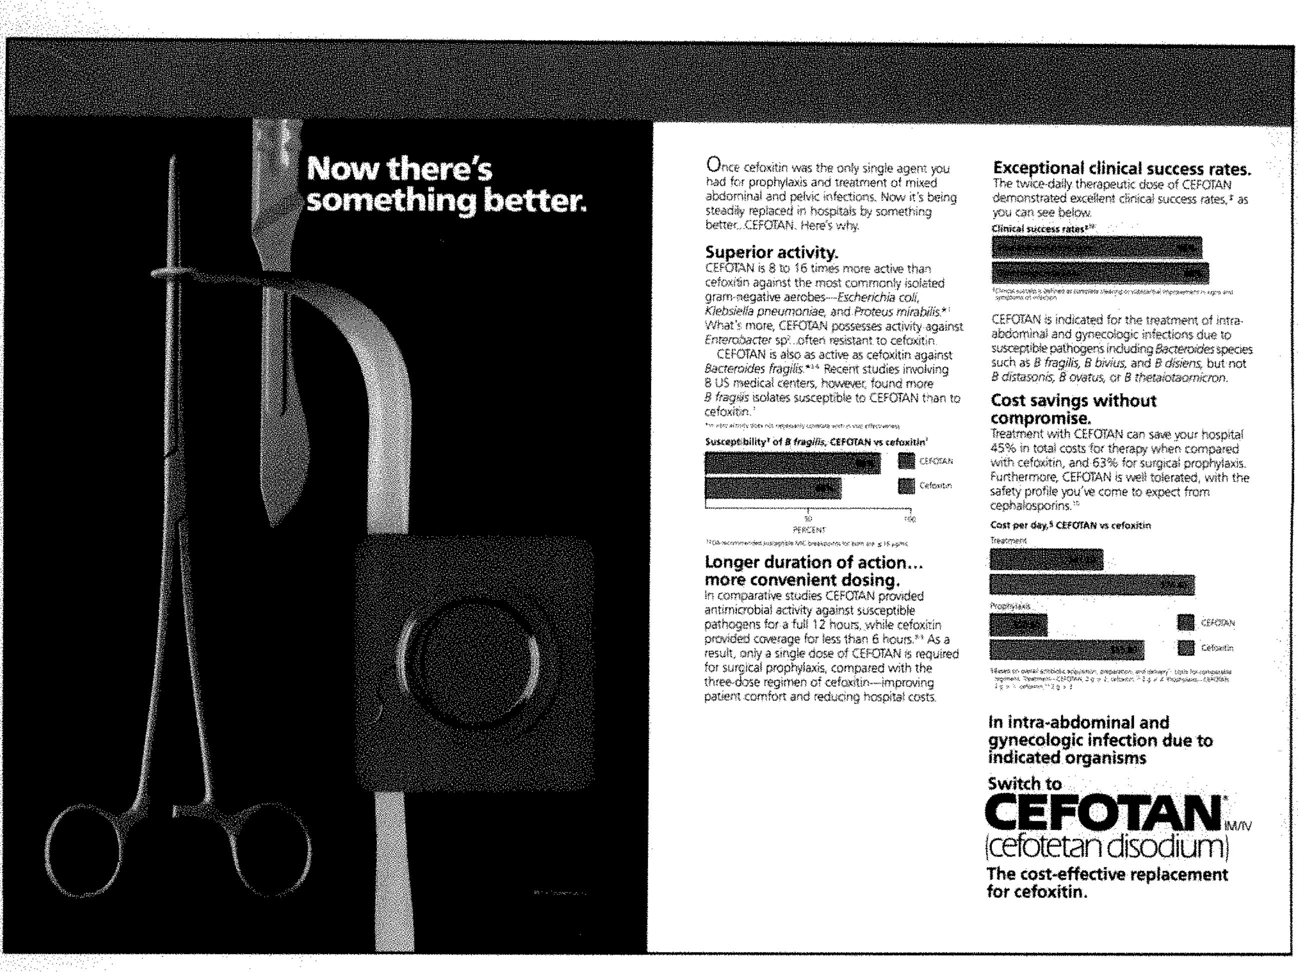


A. The functioning stomach subdivides into discrete"Magenstrasse". Any tube can only evacuate the single gastric stream within which it lies.



B. Study @ 5 minutes. Note effective removal of all excess barium flowing retrograde, none visualized to reach the stomach.

We said.[1]



Now there's something better.

Once cefoxitin was the only single agent you had for prophylaxis and treatment of mixed abdominal and pelvic infections. Now it's being steadily replaced in hospitals by something better...CEFOTAN. Here's why.

Superior activity.
CEFOTAN is 8 to 16 times more active than cefoxitin against the most commonly isolated gram-negative aerobes—*Escherichia coli, Klebsiella pneumoniae,* and *Proteus mirabilis.**[1] What's more, CEFOTAN possesses activity against *Enterobacter* sp[2]...often resistant to cefoxitin.

CEFOTAN is also as active as cefoxitin against *Bacteroides fragilis.**[3,4] Recent studies involving 8 US medical centers, however, found more *B fragilis* isolates susceptible to CEFOTAN than to cefoxitin.[5]

Susceptibility† of *B fragilis,* CEFOTAN vs cefoxitin[5]

Longer duration of action... more convenient dosing.
In comparative studies CEFOTAN provided antimicrobial activity against susceptible pathogens for a full 12 hours, while cefoxitin provided coverage for less than 6 hours.[2,3] As a result, only a single dose of CEFOTAN is required for surgical prophylaxis, compared with the three-dose regimen of cefoxitin—improving patient comfort and reducing hospital costs.

Exceptional clinical success rates.
The twice-daily therapeutic dose of CEFOTAN demonstrated excellent clinical success rates,‡ as you can see below.

Clinical success rates‡

CEFOTAN is indicated for the treatment of intra-abdominal and gynecologic infections due to susceptible pathogens including *Bacteroides* species such as *B fragilis, B bivius,* and *B disiens,* but not *B distasonis, B ovatus,* or *B thetaiotaomicron.*

Cost savings without compromise.
Treatment with CEFOTAN can save your hospital 45% in total costs for therapy when compared with cefoxitin, and 63% for surgical prophylaxis. Furthermore, CEFOTAN is well tolerated, with the safety profile you've come to expect from cephalosporins.

Cost per day,§ CEFOTAN vs cefoxitin

In intra-abdominal and gynecologic infection due to indicated organisms

Switch to
CEFOTAN® IM/IV
(cefotetan disodium)
The cost-effective replacement for cefoxitin.

*CEFOTAN is indicated for the treatment of intra-abdominal and gynecologic infections due to susceptible pathogens including *Bacteroides* species such as *B fragilis*, *B bivius*, and *B disiens*, but not *B distasonis*, *B ovatus*, or *B thetaiotaomicron*.

We all agree.

CEFOTAN® IM/IV (cefotetan disodium).

Does so much for so much less than cefoxitin

Please see next page for brief summary of prescribing information.

In intra-abdominal and gynecologic infection due to indicated organisms

CEFOTAN® IM/IV (cefotetan disodium)

Does so much for so much less than cefoxitin

For Intravenous or Intramuscular Use
BRIEF SUMMARY

INDICATIONS AND USAGE

TREATMENT: CEFOTAN® (cefotetan disodium) is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary tract infections caused by *E coli*, *Klebsiella* species (including *K pneumoniae*), *Proteus mirabilis* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris*, *Providencia rettgeri*, and *Morganella morganii*).

Lower respiratory tract infections caused by *Streptococcus pneumoniae* (formerly *D pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K pneumoniae*), and *E coli*.

Skin and skin structure infections caused by *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis*,* *Streptococcus pyogenes* and *Streptococcus* species (excluding enterococci), and *E coli*.

Gynecologic infections caused by *Staphylococcus aureus*† (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis*,* *Streptococcus* species (excluding enterococci), *E coli*, *Proteus mirabilis*, *Neisseria gonorrhoeae*, *Bacteroides* species (excluding *B distasonis*, *B ovatus*, *B thetaiotaomicron*), *Fusobacterium* species,† and gram-positive anaerobic cocci (including *Peptococcus* and *Peptostreptococcus* species†).

Intra-abdominal infections caused by *E coli*, *Klebsiella* species (including *K pneumoniae*†), *Streptococcus* species (excluding enterococci), and *Bacteroides* species (excluding *B distasonis*, *B ovatus*, *B thetaiotaomicron*).

Bone and joint infections caused by *Staphylococcus aureus*.†

***NOTE:** Some strains of *Staphylococcus epidermidis* are resistant to cefotetan.

† Efficacy for this organism in this organ system was studied in fewer than ten infections.

PROPHYLAXIS: The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (eg, cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

Before therapy with CEFOTAN is instituted, careful inquiry should be made to determine whether the patient has had previous hypersensitivity reactions to cefotetan disodium, cephalosporins, penicillins, or other drugs. This product should be given cautiously to penicillin-sensitive patients. Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs. If an allergic reaction to CEFOTAN occurs, discontinue the drug. Serious acute hypersensitivity reactions may require epinephrine and other emergency measures.

Pseudomembranous colitis has been reported with the use of cephalosporins (and other broad-spectrum antibiotics); therefore, it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use.

Treatment with broad-spectrum antibiotics may alter normal flora of the colon and may permit overgrowth of clostridia. Studies indicate a toxin produced by *Clostridium difficile* is one primary cause of antibiotic-associated colitis. Cholestyramine and colestipol resins have been shown to bind the toxin in vitro.

Mild cases of colitis may respond to drug discontinuance alone. Moderate to severe cases should be managed with fluid, electrolyte, and protein supplementation as indicated. When the colitis is not relieved by drug discontinuance, or when it is severe, oral vancomycin is the treatment of choice for antibiotic-associated pseudomembranous colitis produced by *C difficile*. Other causes should also be considered.

PRECAUTIONS

GENERAL: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity. Those at risk include patients with renal or hepatic impairment, or poor nutritional state. Prothrombin times should be monitored in patients at risk and exogenous Vitamin K administered as indicated.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

INFORMATION FOR PATIENTS: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

DRUG INTERACTIONS: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycoside antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

DRUG/LABORATORY TEST INTERACTIONS: A false positive reaction for glucose in urine may occur with Benedict's or Fehling's solution.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels of Jaffe reaction and produce false increases in the levels of creatinine reported.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

CEFOTAN® (cefotetan disodium)

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approx 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approx 2-4 times the usual human dose), only 1 of 10 treated animals was affected, and the degree of degeneration was mild. Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

USAGE IN PREGNANCY: Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

USAGE IN NURSING MOTHERS: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies the following adverse effects were considered related to CEFOTAN therapy.

Gastrointestinal symptoms occurred in 1.5 percent of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700).

Hematologic laboratory abnormalities occurred in 1.4 percent of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300).

Hepatic enzyme elevations occurred in 1.2 percent of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2 percent of patients and included rash (1 in 150) and itching (1 in 700).

Local effects were reported in less than one percent of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

DOSAGE AND ADMINISTRATION

TREATMENT: The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6* grams	3 g every 12 hours IV

*Maximum daily dosage should not exceed 6 grams.

PROPHYLAXIS: To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION: When renal function is impaired, a reduced dosage schedule must be employed. The following dosage guidelines may be used.

DOSAGE GUIDELINES FOR PATIENTS WITH IMPAIRED RENAL FUNCTION

Creatinine Clearance mL/min	Dose	Frequency
>30	Usual Recommended Dose*	Every 12 hours
10-30	Usual Recommended Dose*	Every 24 hours
<10	Usual Recommended Dose*	Every 48 hours

*Dose determined by the type and severity of infection, and susceptibility of the causative organism.

Cefotetan is dialyzable and it is recommended that for patients undergoing intermittent hemodialysis, one-quarter of the usual recommended dose be given every 24 hours on days between dialysis and one-half the usual recommended dose on the day of dialysis.

HOW SUPPLIED

CEFOTAN is a dry, white to pale yellow powder supplied in vials containing cefotetan disodium equivalent to 1 g and 2 g cefotetan activity for intravenous and intramuscular administration. The 1 g dose is available in 10 mL and 100 mL vials, and the 2 g dose is available in 20 mL and 100 mL vials. The vials should not be stored at temperatures above 22°C and should be protected from light.

1 g in 10 mL vial (NDC 0038-0376-10); 2 g in 20 mL vial (NDC 0038-0377-20); 1 g in 100 mL vial (NDC 0038-0376-11); 2 g in 100 mL vial (NDC 0038-0377-21)

Endotoxemia and Bacteremia During Hemorrhagic Shock

The Link Between Trauma and Sepsis?

BENJAMIN F. RUSH, JR., M.D., ALAN J. SORI, M.D., THOMAS F. MURPHY, M.S., SHARON SMITH, PH.D.,
JOHN J. FLANAGAN, JR., M.D., and GEORGE W. MACHIEDO, M.D.

Previous investigations of a treated model of hemorrhagic shock in the rat indicated the frequent occurrence of bacteremia that appeared to derive from the gut. This paper determines the incidence of bacteremia and endotoxemia during the acute shock period and compares this with similar observations in humans in varying degrees of shock. Studies in 26 rats indicated that bacteremia and endotoxemia was present in 50% and 87%, respectively, by the end of 2 hours at a mean arterial pressure of 30 mmHg. Observations in 50 patients admitted to the trauma unit showed that positive bacterial blood cultures were present in 56% when the admission systolic blood pressure was 80 mmHg or less ($p < 0.01$ compared with either of the other groups). Endotoxemia was noticed in two such patients. Direct access of bacteria and endotoxin to the blood stream may occur during hemorrhagic or traumatic shock and is the probable cause of subsequent sepsis in traumatized patients when no other source is apparent.

From the Department of Surgery, UMD–New Jersey Medical School and the Laboratory Service–V.A. Medical Center, East Orange, New Jersey

OVER THE PAST DECADE and a half, our laboratory, such as many others, has been engaged in the search to identify the specific injury or injuries that cause death after hemorrhagic shock. In the course of this work we became convinced that information derived from conventional shock models of the period was flawed compared with clinical experience because the models represented untreated shock, whereas all clinical experience dealt with treated shock. We developed a model in the rat in which additional Ringer's lactate solution was administered after shock to bring the blood pressure back towards normal levels. The animals also received continuous post-shock maintenance of electrolyte, fluid, and caloric balance. This model tolerates remarkable periods of shock at 30 mmHg mean arterial pressure (MAP) until decompensation has required 80% of the original bled out volume be returned to maintain the selected pressure of 30 mmHg MAP. After this vigorous regimen, almost all animals can be initially resuscitated by return of the remaining blood and the fluid therapy noted above. Nevertheless, a relentless mortality then ensues with all or almost all animals dying by the end of the third post-shock day. Although some organ damage occurs in the model, we were unable to find evidence for initial lethal injuries to any organs, and cellular damage seemed to reverse toward normal in the first 24 hours.[1]

Further experiments with this model showed that a bacteremia developed in many animals during or after shock and that by the third day after shock, almost all of the rats had bacteremia.[2] In addition, survival in this model past the third day could be achieved by treating the animals with antibiotics.[3] Most of the bacteria found in the blood of rats after shock were enteric organisms, suggesting that they came from the rats' gastrointestinal tract. By feeding rats 14C of labeled *Escherichia coli*, we were able to show that the radiolabeled *E. coli* did escape from the gastrointestinal tract during shock and appeared in the blood stream.[4]

All of the work cited above has been presented elsewhere and has been well received, but the most frequent question has been, "how does all of this correlate with what happens in the shocked human?" The following studies were designed to determine what happens to bacterial and endotoxin levels in our animal model during the acute shock period and to compare this with similar observations made in shocked patients presenting to the trauma unit at University Hospital of the University of Medicine and Dentistry of New Jersey.

Materials and Methods

Animals

Male Sprague-Dawley rats with an average weight of 350–450 g were used in all experiments. A total of 26 rats were subjected to a hemorrhagic shock model pre-

TABLE 1. *Blood Culture and Endotoxin Results in Shocked Rats**

Time (min)	N	≥0.1 Endo Units	Gram-positive Organisms	Gram-negative Organisms
0	6	0/6	0/6	0/6
30	6	2/6 (33.3%)	2/6	0/6
60	6	4/6 (66.7%)	1/4	1/4
120	8	7/8 (87.5%)	1/4	1/4

Endotoxin levels greater than or equal to 0.1 EU in the blood of sham shocked or shocked rats at different time periods. Blood cultures were also obtained in some of the rats.

viously described.[1] To ensure a sterile and endotoxin free "shock environment," cannula tubing was flushed with pyrogen-free water before gas sterilization and sterile nonpyrogenic syringes and stopcocks were used.

Blood was collected for blood cultures and endotoxin assay *via* sterile cardiac puncture at 0 time (6 animals), 30 minutes (6 animals), 60 minutes (6 animals), and 120 minutes (8 animals). Blood for endotoxin assay was placed in heparinized (20–30 U of beef lung heparin/ml) nonpyrogenic syringes, which were placed immediately on ice.

Blood cultures were processed by the hospital laboratories at the East Orange Veterans Administration Medical Center by routine laboratory methods. Endotoxin assays were performed using the Quantitative Chromogenic Limulus Amebocyte Lysate assay (QCL-1000 by Whittaker, M.A. Bioproducts; Cat. #50-645U).

Patients

Blood specimens were collected within 3 hours of admission for culture from patients admitted to the Trauma Service. The specimens were obtained simultaneously with other blood drawn by a separate aseptic venous or arterial puncture site. Patients with perforation of any hollow viscus were excluded. Blood cultures were processed by the microbiology laboratories of University Hospital. The patients were divided into three groups: (1) those with an initial blood pressure <80 mmHg; (2) initial blood pressure >80–<110 mmHg; and (3) a control group with blood pressure >110 mmHg and injury not requiring admission to the intensive care unit (ICU) or admitted to ICU only to rule out cardiac contusion but without multisystem injury.

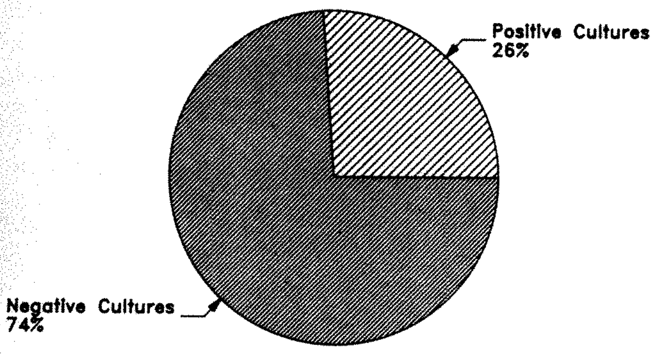

FIG. 1. Incidence of positive cultures in all patients sampled regardless of blood pressure.

Endotoxin Determinations

All glassware was depyrogenated by dry heat incubation at 200 C for a minimum of 24 hours. All nonheat-resistant materials were rendered pyrogen-free by rinsing with pyrogen-free water and subsequently sterilizing with ethylene oxide. Water used for reconstitution and as a diluent was sterile and nonpyrogenic. Blood was aseptically drawn and immediately placed on ice. The blood was centrifuged at 3000 g for 10 minutes at 4 C. Plasma was diluted 1:10 in pyrogen-free water and heated for 10 minutes at 75 C. Quantitative chromogenic assay kits were used for endotoxin determinations. Fifty microliters of the test sample was incubated with an equal volume of Limulus lysate for 30 minutes at 37 C. One hundred microliters of substrate was added and incubated for 3 minutes at 37 C. The reaction was then stopped with 200 μl of 50% acetic acid. Absorbance was read at 405 nm with a Beckman DU-6 spectrophotometer (Beckman Instruments, Inc., Irvine, CA). Standard absorbance curves using *E. coli* 0111: B4 endotoxin prepared by the phenol-water method were performed daily. Each standard and sample specimen was determined in duplicate and corrected for its own blank. Blanks were obtained by adding acetic acid before the substrate. The test detected 0.01 ng of standard endotoxin/ml plasma equal to 0.1 endotoxin units (EU)/ml. Plasma with that value or greater were considered positive.

Statistical Analysis

Statistical significance between groups was determined using the chi-square test.

Results

None of the six sham-shocked rats had significant blood levels of endotoxin or positive bacterial cultures. On the other hand, endotoxin levels of 0.1 EU or higher were observed in 33% of six animals after only 30 minutes of shock and in 88% of the animals after 2 hours of shock. Positive bacterial cultures for gram-positive or gram-negative bacteria or both were found in 50% of rats sampled at 1 and 2 hours of shock (Table 1).

Blood cultures were obtained from 50 patients admitted to our trauma unit; of these 26% were positive (Fig. 1). Twenty-five of these patients were admitted with systolic blood pressures of 110 mmHg or higher and only

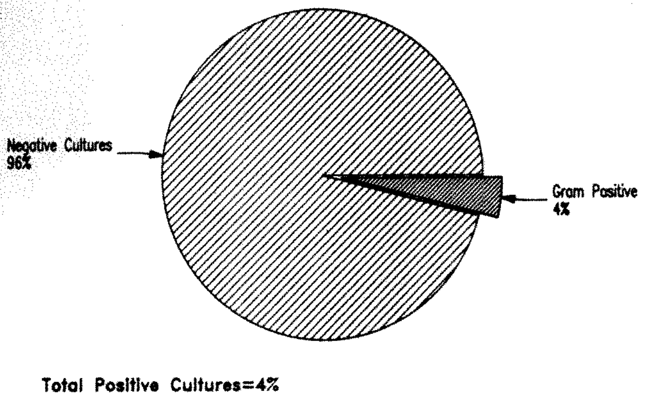

FIG. 2. Incidence of positive blood cultures in patients admitted to the trauma center with blood pressures greater than or equal to 110 mmHg.

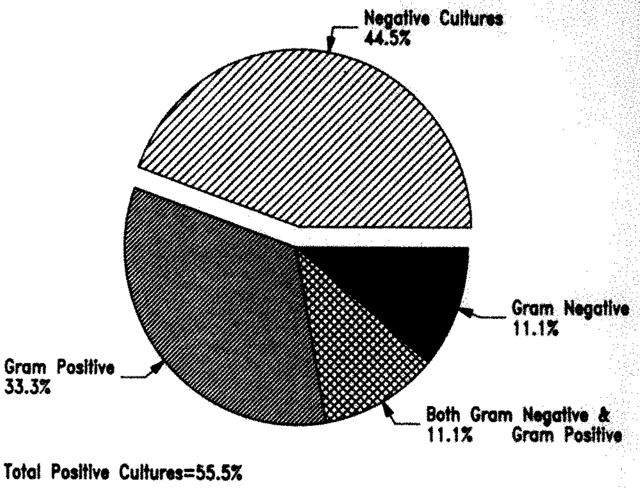

FIG. 4. Incidence of positive blood cultures in patients admitted to the trauma center with blood pressures of 80 mmHg or less.

one patient had a positive blood culture (Fig. 2). This was a gram-positive organism but was not a contaminant as indicated by the fact that the blood cultures were positive for the same organism on two additional days. Despite their higher blood pressures, many of these patients had serious injuries. Three patients (12%) eventually died. The patient with a positive blood culture survived.

Seven patients had systolic blood pressures of greater than 80 mmHg but less than 110 mmHg; of these, two patients had positive blood cultures and both patients survived (Fig. 3). One patient in this group (14%) eventually died.

Eighteen patients were admitted with systolic blood pressures of 80 mmHg or less. In this group there were 10 patients with positive blood cultures (56%). This was a seriously injured group. Average admission blood pressure for the group was 45 mmHg, and all but two patients eventually died. Four deaths occurred in the emergency room, four in the operating room, five in the first 24 hours, two in the first week, and one in the second week. Of the 10 positive blood cultures, six contained gram-positive organisms, two gram-negative organisms, and two contained both (Fig. 4). This was the only group of patients who had blood cultures positive for gram-negative organisms. Figure 5 illustrates the relationship between blood pressure on admission and the presence of positive cultures.

The difference between the lowest blood pressure group and the other two groups in terms of the number of positive cultures was highly significant ($p < 0.01$). Blood samples for endotoxin levels were obtained in 10 patients. In six patients, blood pressure was over 80 mmHg on admission, and none had a clinically significant level of endotoxin in their blood although some were "high normal." Of the four patients with blood

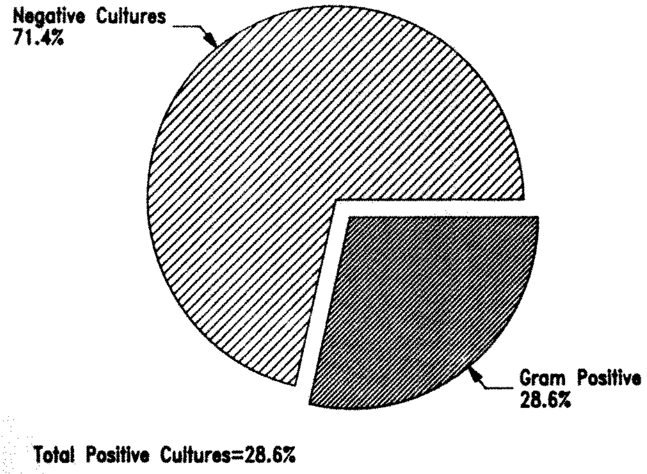

FIG. 3. Incidence of positive blood cultures on patients admitted to the trauma center with blood pressure greater than 80 mmHg but less than 110 mmHg.

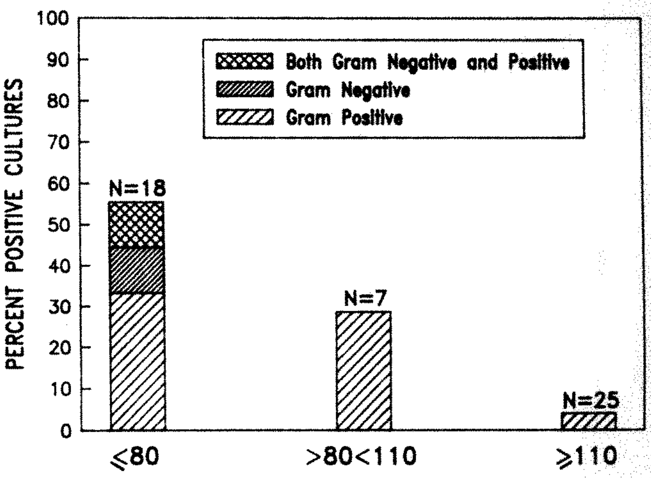

FIG. 5. Correlation of blood pressure with the incidence of positive blood cultures.

pressures of 80 mmHg or less, two had significant endotoxin levels.

Discussion

For centuries physicians have looked at the gut with great suspicion as the source for a multitude of illnesses. Purging was one of the few options available in the therapy of our medical forebears and was often used.[5] In more modern times, several lines of evidence have focused attention on the role of the gut in patients after hemorrhagic shock. Fine[6] produced a series of papers suggesting that the absorption of endotoxin from the gut in the patient in hemorrhagic shock combined with a crippling of the reticuloendothelial system in the liver led to irreversibility of the shock state. An insightful group of papers from Louisville[7,8] have suggested that the organ failure seen after trauma and shock are primarily related to ensuing infection. Deitch and coworkers have demonstrated in a number of elegant experiments in rats and mice that burns and trauma among other conditions lead to the translocation of bacteria from the gut to the mesenteric lymph nodes and sometimes other abdominal organs.[9]

From both our experimental and clinical data, we suggest that one of the important initiating events in the syndrome that follows hemorrhagic shock is the direct absorption of bacteria and endotoxin into the blood of the traumatized, hypotensive patient. We know that cell membranes become hyperpermeable in severe hemorrhagic shock.[10] It should not be surprising that sheets of tissue made up of such shocked cells also become hyperpermeable not only in the gut mucosa but also in capillaries and perhaps lining membranes elsewhere. The frequent finding of gram-positive as well as gram-negative organisms in our traumatized patients may be due to direct injury to the skin or to hyperpermeability of skin structures or of membranes of the upper aerodigestive tract.

We assume that this early bacteremia combined with the well-known damage that occurs to the immune system in the shocked, traumatized patient[11,12] sets the stage for the sepsis and multiorgan failure so often seen in our intensive care units. Like the burned patient and the patient with severe acute pancreatitis, the patient with severe trauma and hemorrhagic shock is subjected to a two-phase process. The first phase is a massive fluid shift and initial extracellular fluid depletion. This may be accompanied by membrane hyperpermeability with bacteremia, which leads to the second phase, which is the septic state. Clinicians have learned to treat the first phase effectively with appropriate replacement of blood and electrolyte fluid. We are still struggling, however, to solve the riddle of appropriate treatment or prevention of the second phase.[13] It is the second phase with its accompanying multiple organ failure that now constitutes what we used to call irreversible shock.[14]

DISCUSSION

DR. EDWIN A. DEITCH (Shreveport, Louisiana): I would like to start off by congratulating and thanking Dr. Rush for not only a nice presentation but for the privilege of reviewing his manuscript.

Dr. Rush has been looking at this field for a number of years, and the data he showed you is very impressive. We, too, have been interested in failure of the gut mucosal barrier, and over the last five years we have used a number of different experimental models to determine under what conditions the gut barrier to bacteria is lost.

We have coined the term "bacterial translocation" to describe this phenomenon, and last year at this meeting, we presented data showing that protein malnutrition and endotoxemia led to failure of the gut mucosal barrier, sepsis, and death in rodents.

We also have been interested in the hemorrhagic shock model. I would like to show you some histology that characterizes the mechanism by which the barrier is lost.

(Slide) Our shock model is not as severe as the one used by Dr. Rush. In our model, rats are subjected to 30 minutes of shock (30 mmHg). In the shocked animal, one can see that there is subepithelial blebbing and edema formation as the intestine is injured.

This slide shows a section of intestine where the mucosal barrier is lost and bacteria are invading the lamina propria.

In attempting to determine the mechanisms responsible for gut failure, we have found that when bacteria translocation occurs, generally one or more of three primary mechanisms are occurring. First is bacterial overgrowth in the intestines, resulting from disruption of the ecology of the gut microflora. This phenomenon is not the explanation for why bacterial translocation occurs after shock.

Secondly, host immune defenses are important in maintenance of physiologic bacterial barrier.

From our studies, it appears that ischemia with physical disruption of the mucosal barrier is the mechanism by which bacterial translocation occurs.

Our concept is that the first line of defense of the gut is either portal blood or lymphatics. If bacteria escape in the portal blood, then liver culture will be positive. If they escape through the lymphatics, then the mesenteric lymph nodes become positive. Positive blood cultures, I think, are only a late sign of gut failure, and I would like to ask Dr. Rush to address the question of whether he thinks a positive blood culture is a *sine qua non* of gut failure.

We found in our shock model that if we pretreated the animal with allopurinol, which blocks xanthine oxidase activation and subsequently oxidant generation, shock-induced bacterial translocation is reduced.

Similarly, if we feed the animals a tungsten diet to inactivate xanthine oxidase, we prevent translocation, and if we scavenge hydroxyl radicals with DMSO, we can prevent translocation.

So we believe that shock-induced bacterial translocation is a reperfusion injury. Additionally, treatment with allopurinol, as well as the tungsten diet also prevents the shock-induced mucosal injuries.

I would like to ask the authors three questions. First, where did the bacteria come from? With gram positive bacteria it is likely that skin, as well as the gut, may be the source.

Have you any information on whether these bacteria are Enterococcus or Staphylococcus, since both Staphylococcus and Enterococcus can originate from the gut. Could bacteria have originated from I-V lines placed in the emergency room?

Secondly, is a positive blood culture too insensitive a test? That is, one needs to have a preterminal patient in which everything has failed, including the liver, the RES system, and so on, before the blood cultures become positive.

And the last question is: What do you speculate the mechanism is by which this is occurring, and do you have any evidence or any plans for further studies to try to reverse this gut failure?

DR. RAYMOND FLETCHER (Nashville, Tennessee): I, too, rise to compliment Dr. Rush on the studies he has done over the years in this particular area, and I have one general comment and a couple of questions.

Dr. Rush, you are aware that the rat mesenteric circulation is very sensitive to vasoactive substances, and I wonder if you have done this in other models, or whether there is a better model to make it more like the human model.

Secondly, in your patients you presented data that demonstrated that there was a very high positive blood culture rate in patients with blood pressures less than 80 mmHg.

Is there a relationship between the time that these patients were in shock and the degree of positivity of their blood cultures, and what percentage of your patients that have survived with positive blood cultures went on to develop systemic sepsis?

DR. FRANK G. MOODY (Houston, Texas): As Dr. Rush has pointed out, his patients had very severe hemorrhagic shock. Most of them died. In addition, his experimental model was also a severe shock model.

At the University of Texas, Houston, and the Hermann Hospital, we have been interested in the other group, the multiple organ failure group, and, to put it in perspective, we see about 2000 injured patients a year. About 1200 make it to the surgical intensive care unit for various periods of time, and about 50 get multiple organ failure.

What is interesting about this group is that most of them had an episode of hemorrhagic shock from which they had been successfully resuscitated, and they have also had their wounds repaired.

By about the seventh day, they begin to appear septic, although in about only half of them are we able to get positive blood cultures at that point in time.

We have taken this to the laboratory in several different ways, and I only mention two. One is to "wire" opossums in order to study their myoelectric potentials and to look at what the gut is doing in terms of propulsion. And it is interesting that just with moderate shock (and by that I mean 60 millimeters of mercury for 60 minutes in an opossum, from which they all recover), it has a profound effect on slowing the peak activity of the myoelectric potentials, and this is what is associated with propulsion down the gut.

So I wouldn't dismiss the concept that bacterial overgrowth may possibly play a role.

Dr. Deitch would be very quick to point out to you that he has not studied small bowel enteric flora, and yet he shows us pictures of the small bowel as being the route of entry of the bacteria.

A second part of the study carried out by Dr. Miller at our institution has involved looking at the small bowel epithelium in translocation. He and his colleagues have found that even moderate shock is associated with epithelial changes at 7 days in rats sustained by parenteral alimentation. There is also a translocation to the lymph nodes and occasionally into the spleen of enteric organisms, but it is not very profound.

I, therefore, would ask Dr. Rush if he has been curious enough to study some survivors, to tell us what their endotoxin levels were and whether, in fact, he has been able to get positive blood cultures similar to what he has obtained in the patients in the emergency center.

DR. R. NEAL GARRISON (Louisville, Kentucky): I wish to congratulate Dr. Rush and his co-authors on a simple but elegant study of endotoxemia and bacteremia during and following hemorrhagic shock both in the clinical and laboratory setting.

This paper clearly links the experimental findings of these authors and the work of Dr. Deitch with the clinical observations of the occurrence of infection and organ system failure that we in Louisville have been studying for several years.

I have two questions for the authors. First, from where were the clinical blood cultures drawn—the venous or the arterial side of the circulation? If the bacteremia is truly of gut origin, then one would expect a higher percentage of positive arterial cultures compared to venous blood samples that have passed through not only the hepatic portal reticuloendothelial system filter, but also the systemic circulatory system of wandering macrophages.

Secondly, along similar lines that Dr. Deitch has previously asked, would the authors care to speculate on the mechanism and timing of the bacteremias? We, as well as others, have shown that under severe stress gastrointestinal flow is greatly diminished. Does the bacteremia occur during this low flow state or with subsequent reperfusion? This latter question would have implications for preventative therapy, such as oxygen-free radical therapy during resuscitation.

DR. HARVEY J. SUGERMAN (Richmond, Virginia): I would just like to give some confirmatory data with regard to Dr. Rush's hypothesis that what is probably going on is major permeability injury. Using a computerized gamma camera to evaluate increased pulmonary permeability, we have found that critically ill, septic ICU patients with a positive study had double the ventilatory time and triple the ICU and hospital stay than patients without a permeability injury. Do you have evidence for increased permeability in other organs, such as in the lung, in these patients?

DR. WATTS R. WEBB (New Orleans, Louisiana): Dr. Rush's study gives us an understanding of some observations we made nearly 25 years ago. We had observed the gross and microscopic changes that occurred in the small and large bowel with hemorrhagic shock. We subjected a group of dogs to total exenteration of the small and large bowel and found that these animals tolerated hemorrhagic hypotension much better than the relatively normal animals. I think now we have some further explanation for this.

DR. BENJAMIN F. RUSH (Closing discussion): I will certainly do my very best to keep all of these questions straight.

Dr. Deitch was curious as to what our information was—as to whether in our human patients blood cultures only were positive or whether other tissues were cultured. To date, all we have available are blood cultures. Of the results from patients, the cultures were entirely from the venous side, either from catheters or from special sites that our research Fellows selected and prepared appropriately.

We were reassured by the fact that our unshocked patients showed negative cultures uniformly, and we assumed that that meant that the incidence of contamination was low or nonexistent, which I guess is a response to the question that I think that Dr. Deitch also asked: How about contamination from I-V lines or other sites?

All patients in this study, whether shocked or unshocked, were injured patients and, there were three deaths in the group of patients who came with blood pressures above 110. There was one death in the group of seven patients who came in with blood pressures between 80 and 110. In most instances, these patients had only single organ injuries or other events. For instance, in the unshocked patients, there was one patient who subsequently died of a pulmonary embolus and one who died of a brain injury.

As for the question as to further studies: I think there is no question that we are going to continue to look at where these bacteria come from and what are the most important sites to be considered, either in terms of prophylaxis or appropriate intervention.

Dr. Moody brought up the question of the great severity of the shock in our patients. There is no question that the group that was admitted with blood pressures of 80 or below was very severely shocked. As I may have mentioned, the mean pressure for the entire group was 45 millimeters of mercury, and it doesn't take much imagination to show that in order to get that rather low mean, some of those patients arrived with a blood pressure of zero and others were fairly low.

Nonetheless, you will notice that there were also some with positive cultures in the group who arrived with pressures above 80, between 80 and 110; so while severity seems to be correlated with the frequency of positive cultures, it is possible to have positive cultures at somewhat higher levels of blood pressure in injured patients.

I might add one other feature. That is, you will notice that while our shocked model is very severe, the data I presented here was for positive blood cultures obtained at measures of 30 mm of mercury for the first 30, 60, and 120 minutes of shock. Obviously, we are already beginning to find positive cultures after as little as 30 minutes of shock in that group.

Finally, have we studied survivors in our patients. In the most severely shocked patients we had only two survivors, so we haven't much to follow with them. We are currently attempting to get sequential studies in those patients with negative and positive blood cultures to determine if, in fact, clinically important sepsis shows up at a later date and how that can be correlated with what we find in the blood of patients on admission.

Dr. Garrison asked about the blood cultures and the source, and I think I have responded to that.

What about the mechanism and the timing of the bacteremia? I believe that will be shown only through future studies. We can speculate, as we already have in this paper, on where the contamination comes from and have suggested membrane hyperpermeability. We suspect that the bacteria don't come from the gut alone, but since we live in a world where bacteria resides in our skin and most of our other organs that connect with the outside world, depending a little bit on the type and dimension of the injury and the depression of the immune system, we speculate that you may well derive bacteria from any such site, that is, skin, lungs, oral cavity, and upper airways, as well as the gut.

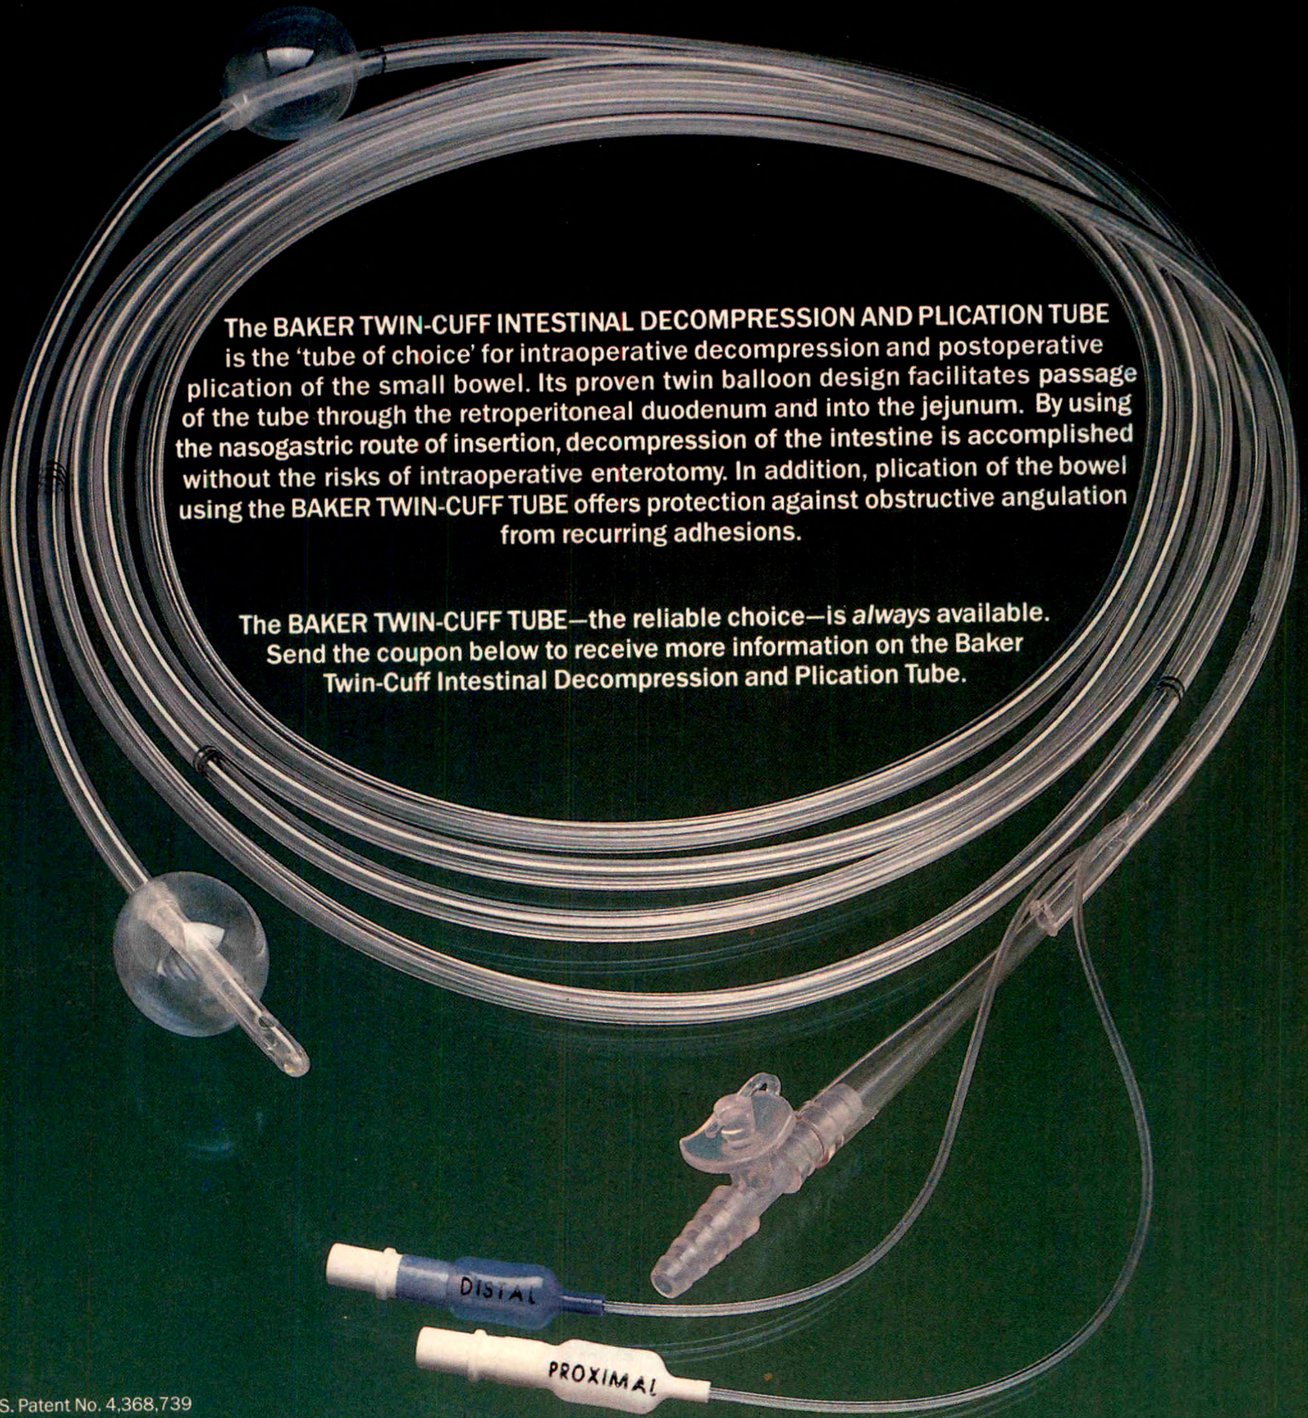
Dr. Fletcher wanted to know about the time it took to deliver these patients and how that correlated with bacteremia. Unfortunately, we haven't done that correlation. I think that is an interesting one. We do have the data and we will be going back to look at that.

The time to sepsis after injury in our patients? Again we have that data, but are still accumulating enough follow-ups for significant observations.

Finally, Dr. Sugerman wants to know about the evidence of increased permeability in other organs. We haven't studied that yet, Dr. Sugerman. We suspect that it happens at a number of sites. In our rat data, it is interesting to note there is a two-phase process following resuscitation. The number of rats with bacteremia decreases transiently and then increases again subsequently, so there seems to be a sort of double phase as you resuscitate the animal; some go on to recovery and some go on to get worse. The initial bacteremia is almost entirely gram-positive while the late bacteremia is gram-negative or mixed.

And finally, Dr. Watts Webb, I did notice your paper. I think the explanation for your result is as you suggest.

BAKER TWIN-CUFF INTESTINAL DECOMPRESSION AND PLICATION TUBE



The BAKER TWIN-CUFF INTESTINAL DECOMPRESSION AND PLICATION TUBE is the 'tube of choice' for intraoperative decompression and postoperative plication of the small bowel. Its proven twin balloon design facilitates passage of the tube through the retroperitoneal duodenum and into the jejunum. By using the nasogastric route of insertion, decompression of the intestine is accomplished without the risks of intraoperative enterotomy. In addition, plication of the bowel using the BAKER TWIN-CUFF TUBE offers protection against obstructive angulation from recurring adhesions.

The BAKER TWIN-CUFF TUBE—the reliable choice—is *always* available. Send the coupon below to receive more information on the Baker Twin-Cuff Intestinal Decompression and Plication Tube.

U.S. Patent No. 4,368,739

Once the tip of the tube has been advanced to the second portion of the duodenum, the proximal balloon, which is still in the stomach, can be grasped and pushed through the pylorus. As the proximal balloon approaches the second portion of the duodenum the distal balloon can be grasped at the ligament of Treitz and the tip of the tube advanced into the jejunum.

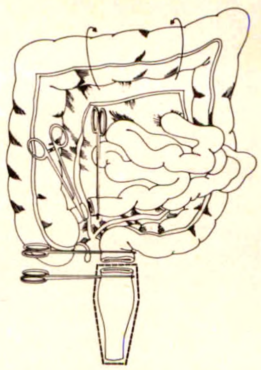
NEW Second Edition!

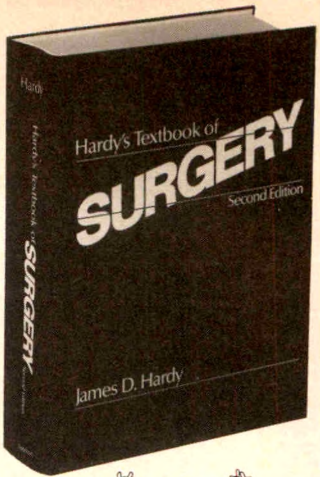
Crisp, comprehensive readable—all you need in compact, practical form!

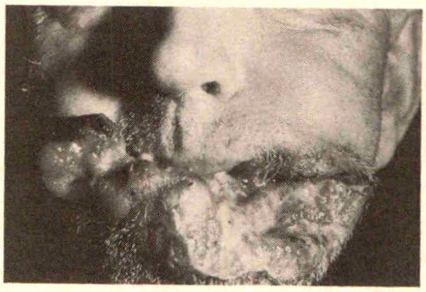
Hardy's Textbook of SURGERY

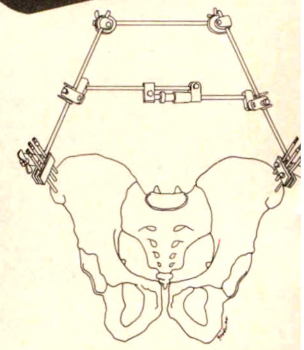
SECOND EDITION

Edited by **JAMES D. HARDY, M.D.**
with 119 Contributors









Concise, comprehensive, practical—and up to 40% shorter!

The notable features of the first edition of this remarkable text were its comprehensiveness and its concise treatment of the subject. These features have been retained and strengthened in the second edition—once again 30% to 40% shorter than other textbooks of surgery while scrupulously covering the basic principles of surgical diagnosis and treatment. Crisp. Pithy. Above all, highly *practical* as a day-to-day reference.

Tightly organized—you can review information rapidly

The book captures the principles of surgery in tightly written, rigorously organized chapters. Part One covers basic and support considerations, those aspects of the field that are applicable to any surgical procedure, such as patient response to surgery, shock and cardiac arrest, respiratory support, wound healing, infections, preoperative preparation, and anesthesia. Part Two is organized by specific organs and organ systems, and systematically describes surgical principles and procedures. Basic science discussions are confined to applied physiology and anatomy in specific clinical situations.

New in the Second Edition

- *all material reviewed, and much extensively rewritten*
- *several new contributors strengthen coverage in areas where major developments are taking place*
- *many new illustrations of operative technique*
- *completely new index*
- *completely new chapter on Response to Surgery*
- *new material and especially significant revisions in the chapters on Nutrition in Surgical Patients; Trauma; Anesthesia; The Breast; The Mesenteric Small Bowel; The Lung; Gynecologic Surgery; and the Appendix*
- *new sections on GI hormones and the gallbladder-biliary tract*
- *entirely rewritten chapter on Orthopaedic Surgery*

High Praise for the First Edition

“. . . concise, current, clinically relevant, and, moreover, readable . . . commendably, Hardy and the contributing authors are cognizant of what general surgery entails today . . . just may become the gold standard.”

—*Mayo Clinic Proceedings*

“. . . an important addition to current general surgery textbooks . . . comprehensive . . . easy to read and review.”

—*New England Journal of Medicine*

“. . . I commend the author for accomplishing his stated goals of providing a standard textbook of surgery that includes concise coverage of basic subjects of general surgery with appropriate supportive science and emphasis on what is clinically relevant. I heartily recommend this book.”

—*Annals of Surgery*

About 1,440 Pages. 559 Illustrations. 170 Tables.
2nd Edition, 1988. Hardcover $55.00.
Flexible Binding $39.95.

NO-RISK GUARANTEE!

Take advantage of our 30-day, no-risk guarantee, and examine this superb new edition at leisure. Evaluate its usefulness in your practice. Order your copy today.

The Atriocaval Shunt

Facts and Fiction

JON M. BURCH, M.D., DAVID V. FELICIANO, M.D., and KENNETH L. MATTOX, M.D.

During the past 11 years, 31 patients with major juxtahepatic venous injuries were treated with the atriocaval shunt. Penetrating injuries occurred in 27 patients (87%), and injuries from blunt trauma occurred in four patients. Shock was present on admission in 28 patients (90%). Resuscitative thoracotomy for cardiovascular collapse was required in 13 patients (42%). Juxtahepatic venous injuries included the vena cava in 23 patients (74%) and the hepatic veins alone in five patients (16%). One patient had an isolated portal venous injury, and two patients died before their vascular injuries could be delineated. Technical problems related to the shunt occurred in seven patients. Most were related to delays in placement or problems encountered in obtaining vascular control of the suprarenal vena cava. Major hepatic resection was performed in 11 patients (35%). Twenty-five patients died of their injuries. No patient survived who required resuscitative thoracotomy, hepatic resection, or when technical problems with the shunt occurred. Six patients (19%) survived and were discharged from the hospital. All sustained gunshot wounds to the retrohepatic vena cava. Four of the six survivors had serious postoperative complications, but none were related to the shunt. Major juxtahepatic venous injuries are highly lethal. The atriocaval shunt will permit the salvage of some patients where other methods are not possible. Avoidance of delay and alternative shunting techniques that eliminate difficult maneuvers may improve survival in the future.

From the Cora and Webb Mading Department of Surgery,
Baylor College of Medicine, and The Ben Taub
General Hospital, Houston, Texas

THERE ARE FEW TECHNICAL MANEUVERS in surgery as dramatic or desperate as the use of the atriocaval shunt in the management of patients with injuries to the major juxtahepatic veins. Invariably, the patient is on the brink of exsanguination and the surgeon is unlikely to attain hemostasis using conventional techniques. These injuries are fortunately rare, but when they are encountered, the surgeon must have a plan for controlling the hemorrhage and repairing the vascular injuries. The usual approach has been with the use of the atriocaval shunt.[1-5] Some surgeons, however, have expressed concern about difficulties or high mortality rates associated with the use of the shunt.[6-9] The atriocaval shunt has been used at this institution to treat many injuries involving the suprahepatic vena cava, retrohepatic vena cava, and hepatic veins which have been encountered. The purpose of this review is to analyze the procedures performed during the past 11 years emphasizing the indications, results, techniques, and pitfalls with the atriocaval shunt in the management of these lethal injuries.

Clinical Material and Methods

From January 1, 1977 through November 20, 1987, 31 injured patients were treated at Ben Taub General Hospital in Houston, Texas, with the atriocaval shunt. All patients in this series are listed and numbered individually for reference. Table 1 lists all nonsurvivors who required resuscitative thoracotomy, Table 2 lists all nonsurvivors who did not require resuscitative thoracotomy, and Table 3 lists all survivors.

All patients were males with an average age of 30 years (range: 14–64 years). Penetrating injuries occurred in 27 patients (87%), and included 21 with gunshot wounds and six with stab wounds. Blunt trauma was responsible for the injuries of four patients, including two motorcycle accidents, one automobile accident, and one fall.

Prehospital care was administered by the paramedics and emergency medical technicians of the Houston Fire Department. During the study period, average prehospital time was reduced from 40 minutes in 1977 to 25 minutes in 1987. On arrival to the emergency center,

room.[10] Eleven patients (35%) underwent resuscitative thoracotomy in the emergency center. In addition, two patients had cardiovascular collapse in the operating room before the induction of anesthesia and required resuscitative thoracotomy. Overall, 13 of 31 patients (42%) required resuscitative thoracotomy.

The length of time from admission to the time the patient arrived in the operating room was determined for 28 patients. There were 21 patients (68%) operated on within 30 minutes of arrival in the emergency center, and eight patients operated on between 45 and 540 minutes after admission. Two patients had rebleeding after repair of injuries without the atriocaval shunt and had shunts placed to control the hemorrhage during reoperation. Both patients had missed injuries, and their times from admission to operation were not determined. For one patient, this time could not be determined with precision.

The diagnosis of injuries requiring an atriocaval shunt was made at the time of operation in all cases. Often, injuries involving the juxtahepatic vasculature were suspected on the basis of the location of missiles in and around the lower thoracic and upper lumbar spines on chest x-rays. At the time of abdominal exploration, profuse venous hemorrhage from behind the right lobe of the liver, into the lesser sac, or posterior to the porta hepatis suggested injury to the retrohepatic vena cava. Hemorrhage near the diaphragm suggested injury to either the suprahepatic vena cava, retrohepatic vena cava, or hepatic veins. Patients with severe parenchymal liver injuries, in whom a Pringle manuever failed to control hemorrhage, were suspected of having injuries to the retrohepatic vena cava or hepatic veins. Unusual presentations occurred in four patients: three had hemorrhage into the right hemithorax and one had a pericardial tamponade.

The incisions used were dependent on the patient's initial condition. Nine patients requiring resuscitative thoracotomy had bilateral anterolateral thoracotomies before midline abdominal incisions. Of the four remaining patients treated with resuscitative thoracotomy, two had left anterolateral thoractomies extended into left thoracoabdominal incisions and two had median sternotomies connected to midline laparotomies. Three patients underwent initial right anterolateral thoracotomies. When the hemorrhage was noted to come through a defect in the diaphragm, midline incisions were performed. On recognition of the nature of the injury, two patients had conversions to bilateral anterolateral thoracotomies and one had an extension into a right thoracoabdominal incision. The remaining 13

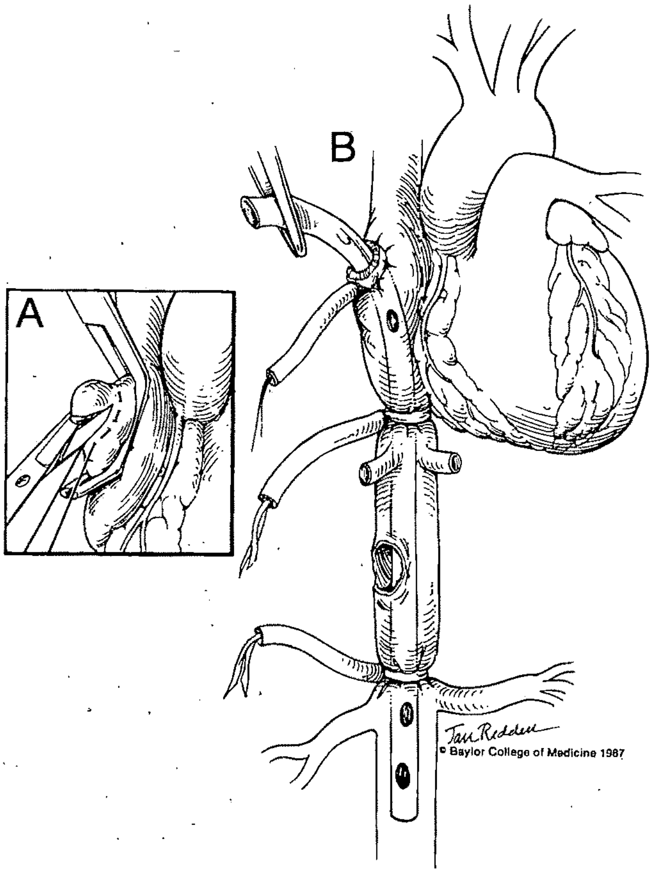
patients had midline abdominal incisions followed by extension with a median sternotomy.

Injuries for which the shunt was placed are listed in Table 4. Twenty-three patients (74%) had injuries to the inferior vena cava, whereas the hepatic veins were involved in 13 patients (42%). One patient, no. 22, had an intrahepatic portal vein injury that was not controlled with the initial Pringle maneuver as evidenced by persistent hemorrhage from beneath the porta hepatis. Two patients with devastating injuries exsanguinated as the shunt was being placed and did not have the extent of their juxtahepatic vascular injuries delineated.



FIGS. 1A and B. *A*. Properly positioned atriocaval shunt fashioned from a chest tube. *B*. Atrial purse string suture and incision in atrial appendage.

Associated injuries are listed in Table 5. All patients in the series had hepatic injuries. In 13 patients (42%), the injury to the hepatic parenchyma was judged to be severe, *i.e.*, life-threatening in its own right. One patient had a severe pulmonary hilar injury requiring pneumonectomy. Another patient had an aortic injury at the level of the diaphragm severe enough to require prosthetic graft replacement. Two patients had severe intracranial injuries.

Aortic clamping was used to maintain perfusion to the coronary and cerebral circulation in 25 patients (81%). All 13 patients with resuscitative thoracotomy had the thoracic aorta clamped. Ten of the 12 nonsurvivors (83%) without resuscitative thoracotomy, and two of the six survivors (33%) had the aorta clamped at the diaphragm.

The device most often used for vascular isolation was a 36 French chest tube. The shunt was usually inserted through the right atrial appendage and secured at the intrapericardial vena cava and suprarenal vena cava with Rumel tourniquets (umbilical tape snares) (Fig. 1). In seven patients, the size of the shunt was not stated, and in one patient, a 28 French chest tube was used. An additional hole, approximately the size of the internal diameter of the chest tube, was cut 20 c from the closest of the drainage holes. In three patients the shunt was placed through a venotomy in the infrarenal vena cava and secured in the same fashion as those inserted through the atrium. In the most recent patient, difficulties encountered in surrounding the suprarenal vena cava resulted in the use of a 9-mm internal diameter plastic endotracheal tube with omission of the lower tourniquet (Fig. 2).

The shunt was successfully placed in 27 of 31 patients (87%). Four patients were exsanguinated as a result of their injuries while the shunt was being secured. Despite the successful placement of the shunt in 27 patients, only 15 patients (48%) lived long enough to have their injuries repaired.

Eleven patients had hepatic resections performed. There were nine anatomic lobectomies (one for exposure of a retrohepatic vena caval injury only) and one left lateral segmentectomy. In patient no. 14, the entire liver was avulsed from the vena cava and hepatic pedicle. After placement of the atriocaval shunt, the liver was lifted from the abdomen for bench repair of vascular injuries; however, the patient died before reimplantation could be performed. In the patient with the isolated portal vein injury (Table 2), the lobectomy was performed at a reoperation for hepatic necrosis and not during the previous procedure for hemorrhage when the shunt was used.

Results

Twenty-five patients (81%) died of their injuries. Of the 25 nonsurvivors, 21 (84%) exsanguinated in the operating room. Four patients who ultimately died left the operating room alive. Two had persistent hemorrhage after repair of their vascular injuries. Patient no. 16 continued to bleed while in the intensive care unit and died of shock and exsanguination. Patient no. 23 initially had successful control of hemorrhage but developed recurrent bleeding a few hours after the original operation. This patient was taken back to the operating room at which time the bleeding was noted to originate from severe bilobar hepatic injuries. He subsequently died in the operating room. Patient no. 25 died of refractory shock 12 hours after surgery despite successful repairs. This patient was 64 years old and had injuries to both the suprahepatic vena cava and the posterior aspect of the intrapericardial vena cava. Patient no. 22 died of multisystem failure and sepsis on the sixth postoperative day.

Unlike previous series,[11] the number of associated injuries, *per se*, did not adversely influence mortality rate. The average number of associated injuries for survivors in this study was 3.3, and the average number of associated injuries for nonsurvivors was 2.5. In contradistinction to the number of associated injuries, the severity of individual associated injuries did affect outcome. All patients with severe hepatic parenchymal injuries and those treated with hepatic resection died. In one of these cases, the patient did not have a severe hepatic injury, but the resection was performed to expose a stab wound in the retrohepatic vena cava. Two patients had severe intracranial injuries that were not likely to be compatible with survival. The patient with the suprarenal aortic injury also did not survive.

The mechanism of injury did influence survival, although not as anticipated. All patients sustaining stab wounds and blunt trauma died. The reason for the deaths in those patients with stab wounds is most likely related to their condition on arrival to the hospital. In three patients, resuscitative thoracotomy was required. The remaining three were in shock on arrival, and two were treated by hepatic resection. It is possible that the added blood loss associated with hepatic resection may have affected the outcome of these latter cases.

The patient's condition on admission to the emergency center correlated with survival. All patient's requiring resuscitative thoracotomy died. Furthermore, all patients who died were in shock on admission. Twenty-three of the 25 patients (92%) who required aortic clamping died. Technical problems with the use of the shunt occurred in seven patients (Table 6). The majority were related to delays in decision making or difficulties encountered in placement of the lower Rumel tourniquet. All seven of these patients died.

gunshot wound that injured the retrohepatic vena cava. No survivors required either resuscitative thoracotomy or hepatic resection. Of the three survivors who were in shock on admission, two were operated on within 15 minutes of their arrival. The three patients who were not in shock on admission survived.

Four of the six survivors had serious postoperative complications (Table 7). Three patients had intra-abdominal abscesses that required surgical drainage. In one patient, a colocutaneous fistula developed several weeks after drainage of an intra-abdominal abscess. This patient ultimately required treatment with proximal fecal diversion. One patient, no. 29, in whom an intrahepatic abscess developed, had an anterior defect in the retrohepatic vena cava tamponaded by approximating the hepatic parenchyma over the vascular injury. This was done after a successful suture repair of a posterior hole in the retrohepatic vena cava to avoid extensive hepatic dissection. The intrahepatic abscess was treated satisfactorily by percutaneous drainage. Three patients had respiratory failure and required prolonged endotracheal intubation and ventilation. Two patients had postoperative hemorrhage and required prompt reoperation. One patient had a partial small bowel obstruction that was treated conservatively. Only a single survivor had an uncomplicated recovery. The length of hospital stay for survivors ranged from 11 to 198 days with an alarming average of 71 days. No survivors had long-term sequelae as a result of the shunt.

Discussion

The first clinical use of the atriocaval shunt was by Shrock et al. in 1968.[1] From dissections of human cadavers, they made the observation that there were no venous tributaries other than the hepatic veins, right adrenal vein, and inferior phrenic veins that entered the inferior vena cava above the level of the renal veins. With this vital information, they devised a technique for maintaining venous return from the renal veins and the infrarenal vena cava to the right atrium, and producing a relatively bloodless field with the addition of a Pringle maneuver. They reported the use of this technique in a child who sustained blunt trauma to the liver with injury to the hepatic vein. Although the child did not survive, the report stimulated great interest in other major trauma centers. Bricker and co-workers, from this institution, reported the first patient to survive a repair of injuries to the hepatic vein and retrohepatic vena cava with the use of the atriocaval shunt in 1970.[12] One year later, Bricker et al. reported a second survivor whose extensive injury to the retrohepatic vena cava was also treated with the atriocaval shunt.[2] Other successful cases were reported by Brown et al.,[13] Yellin et al.,[3] Fullen et al.,[4] and Turpin et al.[5] These early successes added enthusiam for the use of the shunt; however, as Walt pointed out by in 1978, not everyone had been able to achieve the results reported by others.[6] Kudsk et al. reported a decade of experience with this technique at San Francisco General Hospital in 1982.[11] The shunt was placed in 18 injured patients, and there were four long-term survivors. One additional patient lived for 45 days. Despite this cautiously optimistic report, pessimism still remained. In 1986, Pachter et al. reported six consecutive patients with juxtahepatic venous injuries managed without the shunt, and five of the six survived.[9] He clearly demonstrated that the use of the atriocaval shunt was not a prerequisite for the successful management of all patients with these injuries.

Until recently, reports of patients surviving blunt trauma requiring the atriocaval shunt have been rare.[14] In 1987, Rovito published a remarkable series in which four of nine patients sustaining blunt trauma to the liver or juxtahepatic veins survived after treatment with the atriocaval shunt.[15] It was this report, to a large extent, that stimulated an interest in reviewing our own techniques and results.

Evaluation of the Current Series

There is no question that the mortality rate for injuries to the retrohepatic vena cava, suprahepatic vena cava, and hepatic veins, despite the aggressive use of the atriocaval shunt, remains exceptionally high. In view of Pachter's superb results in managing these injuries without the shunt, one is forced to ask the question as to whether the atriocaval shunt was responsible for the high mortality rate in the current series. Several observations make that conclusion unlikely. The fact that 42% of the patients in this series required resuscitative thoracotomy suggests that prehospital or preoperative blood loss and shock are major contributing factors. Survival rates for patients sustaining either blunt or penetrating abdominal trauma requiring resuscitative thoracotomy at this institution have usually been in the range of 3%.[10] If these patients are excluded from survival statistics, then six of 18 patients (33%) would have survived. Nevertheless, the mortality rate still remains high even when resuscitative thoracotomy is not required.

In the past, prehospital delay has been cited as being in part responsible for the significant mortality associated with injuries to the vena cava.[16] It was believed that these delays resulted in a large percentage of patients presenting to the hospital in shock. During the current study, the average prehospital delay dropped from 40 minutes to 25 minutes; at the same time the percentage of patients with vena caval injuries presenting in shock rose from 44% to 55%. This implies that more patients with severe hemorrhage and shock are reaching the hospital alive than before, an obvious characteristic of this series. This conclusion is further supported by operative observations from the three groups of patients in Tables 1, 2, and 3. The most critically ill, those requiring resuscitative thoracotomy, had on the average a lower pH, lower core temperatures, shorter operations, and less blood administered than did those who died but did not require resuscitative thoracotomy, or the survivors (Table 8). The same statement also can be made in comparing the latter two groups. This strongly suggests that nonsurvivors died so precipitously from pre-existing shock and hemorrhage that they did not live long enough to be given as much blood during the operation as did the survivors. A technique for gaining hemostasis would be most unlikely to produce this result.

Another factor that may bias these results is the fact that not all juxtahepatic vascular injuries treated at this institution have required the use of a shunt. During the study period, 15 additional patients were treated for injuries to the retrohepatic vena cava without an atriocaval shunt. Seven of the 15 patients survived. The overall survival rate for all patients sustaining retrohepatic vena caval injuries during the study period was 37%. Similar data are not available for patients with hepatic venous injuries because many of these patients are treated with more conservative techniques such as parenchymal suture.[17] The use of the shunt at this institution is reserved for patients with more severe injuries who cannot be treated using simpler techniques. Finally, there were no instances in this series where the application of the atriocaval shunt was believed to be directly or in part responsible for any deaths. Therefore, in the opinion of the authors, it was the extent of the patient's injuries, the rate of their hemorrhage, and the severity of their shock that resulted in a high mortality rate rather than the use of the atriocaval shunt.

Decision Making

Recognizing the need to use the atriocaval shunt is not always easy. This can lead to disastrous delays as massive blood loss continues. The following operative findings imply that the shunt may be needed. With secure occlusion of the hepatic pedicle (Pringle manuever), profuse venous hemorrhage: (1) from the posterior aspect of the right lobe of the liver, usually through the caudate lobe; (2) into the lesser sac in the absence of a portal venous injury; (3) at the diaphragm anteriorly; (4) from deep within the hepatic parenchyma; or (5) from beneath the porta hepatis indicates that injury to the retrohepatic vena cava, suprahepatic vena cava, or the hepatic veins exists. Unusual presentations may also occur, including hemorrhage into the right hemithorax and pericardial tamponade.

TABLE 8. *Intraoperative Averages of Physiologic Parameters, Length of Operation, and Red Blood Cell Replacement in 31 Patients According to Preoperative Status and Outcome*

Preoperative Status and Outcome	Lowest pH	Lowest Temperature (C)	Length of Operation (hours)	RBC Units Given
Resuscitative thoracotomy and died (N = 13)	7.03	31.2	1.2	18.4
Without resuscitative thoracotomy and died (N = 12)	7.11	31.6	1.9	27
Survived (N = 6)	7.23	32.6	4.9	30

The surgeon should attempt to palpate the region of the injury to determine the size of the defect. Excessive time should not be spent in this endeavor as significant blood loss may continue. If the lesion is palpable and small, it may be prudent to continue dissection to expose the defect and repair it without a shunt. If the defect is large (greater than 1.0–2.0 cm in diameter) the use of the atriocaval shunt is highly desirable unless clamp control can be easily achieved.

The importance of the Pringle maneuver cannot be overemphasized. Not only does this technique control blood loss, it also plays a pivotal role in decision making. Obviously, if the hemorrhage is controlled with a Pringle maneuver, a shunt is not necessary.

Even with the best intentions, pernicious delay may occur. This can result from difficultly in making a diagnosis or from inexperience and a reluctance to expand the scope of the operation. This is understandable since injuries requiring the atriocaval shunt are rare. During the study period, 268 vena caval injuries were treated, and only 9% required the use of the shunt. Furthermore, during the same period, 1782 hepatic injuries were treated, and the shunt was required in only 1.8% of these cases. The decision to place the shunt, with the subsequent finding that it may not have been necessary, should not be harshly criticized.

FIGS. 3A–C. *A.* Preferred thoracic incision for patients not requiring resuscitative thoracotomy. *B.* Proper position for lower tourniquet is around suprarenal vena cava in abdomen. *C.* Proper position for upper tourniquet is around intrapericardial inferior vena cava.

Maintaining hemostasis, before and during placement of the shunt, is crucial to survival. In most cases, particularly those associated with severe hepatic injuries, posterior compression of the liver with laparotomy pads in addition to a Pringle manuever will be satisfactory.

Adequate exposure is also mandatory. In patients who have not required emergency thoracotomy, extension of the midline abdominal incision into a complete median sternotomy affords ideal exposure. Radial division of the diaphragm to the adventitia of the inferior vena cava is often necessary. Great care must be taken when completing this incision because the tough diaphragmatic fascia at the vena caval hiatus yields suddenly to expose the delicate inferior vena cava beneath. For patients with initial anterolateral thoracotomy, division of the lower portion of the sternum will also facilitate exposure although closure may be awkward. Achieving adequate exposure and maintaining hemostasis are not always compatible. This is especially true when attempting to surround the suprarenal vena cava for placement of a Rumel tourniquet. Posterior compression of the liver increases the difficulty of exposing the suprarenal vena cava. This dilemma has led to minor injuries of the suprarenal vena cava that required repair in two patients in the current series.

Once the decision has been made to use the atriocaval shunt, many options regarding size, style, and route of insertion are available. The ideal size of the shunt has yet to be determined. It should be large enough to permit adequate venous flow under low pressure conditions and yet not so large as to be cumbersome. Thirty-six French chest tubes were often used in this series, although smaller ones have been successfully used. The advantages of chest tubes are their availability and flexibility. They can be inserted from either the atrial or vena caval approach and are available at all times and in all hospitals. The main disadvantage of the chest tube is the need to control the suprarenal vena cava with a Rumel tourniquet. Cannulation through the right atrial appendage is preferable since this is a readily accessible and easily controlled route with the aid of the curved Glover or Satinsky clamp (Fig. 1 inset). Cannulation of the infrarenal vena cava may be desirable for surgeons uncomfortable with atrial cannulation or in patients with an existing anterolateral thoracotomy because the external end of the shunt may rub annoyingly against the exposed upper costal margin.

Their are two styles of shunts: straight tubes and those with inflatable balloons at one end or both. Specially constructed balloon tipped shunts have been used experimentally[18,19] and clinically.[8,20,21] These catheters, depending on design, may be inserted from either only the atrial or infrarenal approach. Two balloon shunts were designed for insertion *via* the femoral vein.[20,21] This approach offers the advantage of not requiring an incision in a large venous structure, but suffers from the drawback of requiring an additional incision and dissection. A potential shortcoming of special devices that are seldomly used is that they may be difficult to find expeditiously in a large operating room suite. The use of an endotracheal tube, first described by Yellin et al.,[3] and used so successfully by Rovito,[15] is an attractive alternative. It is instantly available from the anesthesiologist and comes sterilely packaged.

Technique

The atriocaval shunt increases the complexity of the operation, and critical maneuvers must occur simultaneously. It is essential that a single individual direct these operations. A median sternotomy is the perferred thoracic incision (Fig. 3A). The control of hemorrhage with posterior compression of the liver and a Pringle maneuver is vital and must be performed as soon as the diagnosis is suspected. This will enable the anesthesiologist to correct existing volume deficits and metabolic derrangements before proceeding. It may be desirable at this point to remove previously applied aortic clamps or at least move them to below the level of the renal arteries.

The next step is to prepare the shunt. For chest tubes, a hole is cut 20 cm from the nearest drainage hole. If an endotracheal tube is used, the distance should be somewhat less, 17–18 cm from the nearest hole past the balloon. Care must be taken not to damage the inflation lumen of the balloon.

The end of the shunt that will be outside of the heart or vena cava is securely clamped. Although many have made the recommendation to use this end as an intravenous infusion site, adaptors may be difficult to find and the technique adds unnecessary complexity. Also, complications such as air embolism may occur. Control of the suprarenal vena cava with a Rumel tourniquet should be obtained (Fig. 3B). This treacherous step is omitted if a transatrial endotracheal tube is used. Next, a Rumel tourniquet is placed around the intrapericardial inferior vena cava (Fig. 3C). A partially occluding clamp is then applied on either the right atrial appendage or infrarenal vena cava and a purse string suture is placed. After making an incision encompassed by the purse string, the clamp is removed and the tube is inserted and directed toward the liver. When passing the tube from above, care must be taken not to insert the shunt into the hepatic or renal veins. The surgeon controlling the operation should palpate the retrohepatic vena cava and guide the tube into the correct location. The purse string should then be secured with a Rumel tourniquet and all tourniquets secured or balloons inflated. The position of the shunt should be evaluated by palpation above and below both Rumel tourniquets to ensure that all the holes in the shunt are outside of the area of vascular isolation.

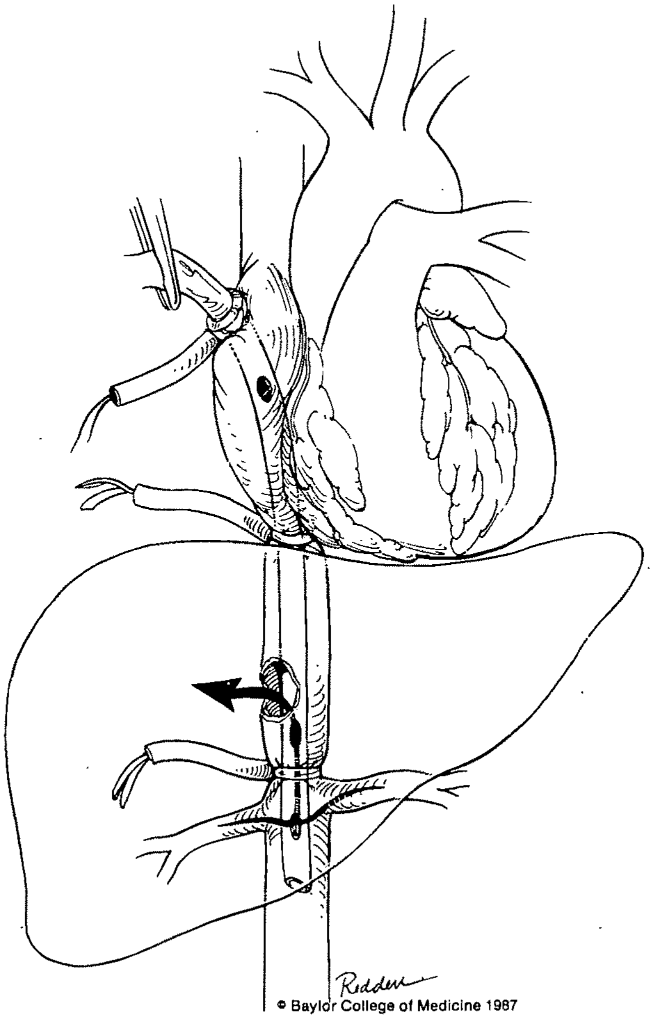

FIG. 4. If chest tube is positioned so that not all holes are below the lower tourniquet, persistent hemorrhage from the venous injury will occur.

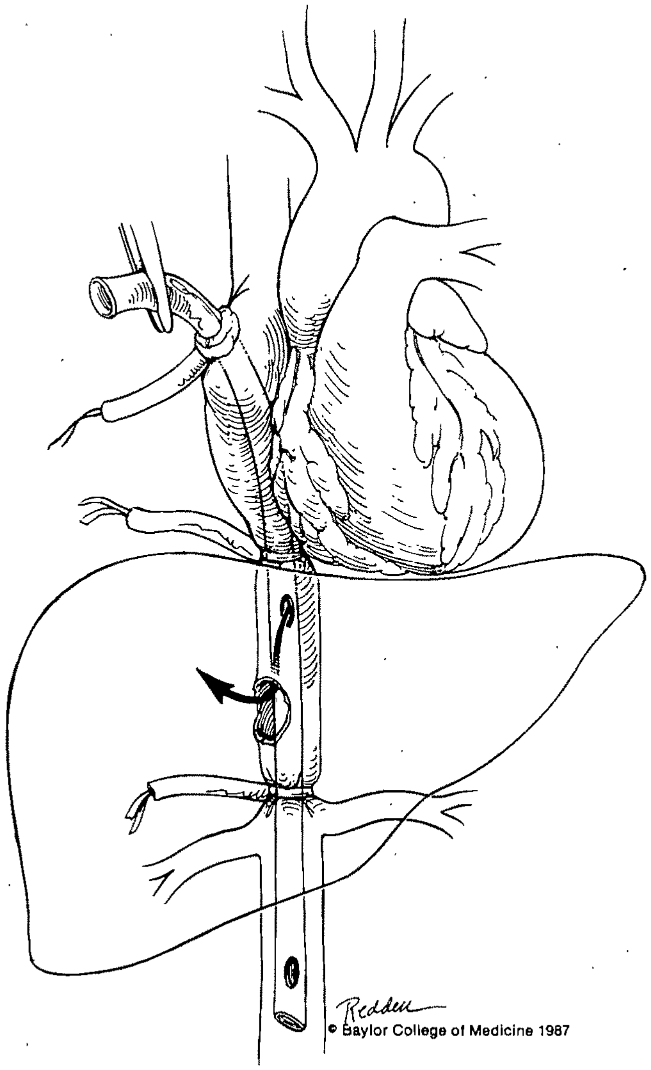

FIG. 5. If atrial drainage hole is positioned below the intrapericardial tourniquet, hemorrhage will continue and venous drainage from the lower body will not reach the heart.

Due to the fact that the hepatic veins and isolated segment of the vena cava may drain residual blood, and that the right adrenal vein, inferior phrenic veins, and perhaps aberrant tributaries may be within the area of vascular isolation, some bleeding usually persists from the vascular injury. The amount of blood loss that occurs, although potentially significant, is trivial com-

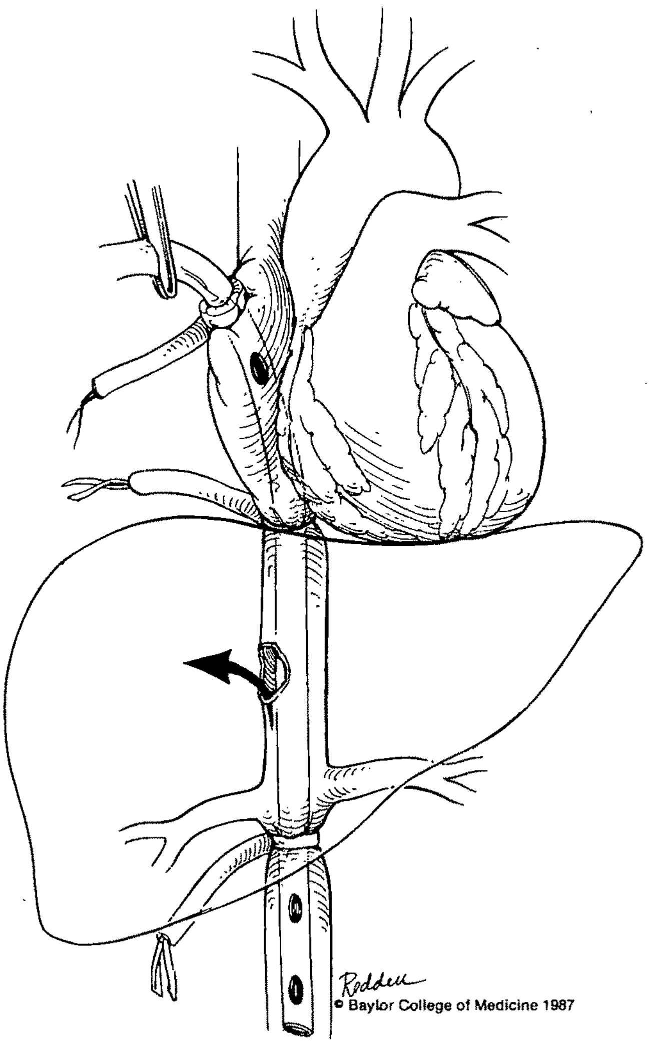

FIG. 6. If lower tourniquet is positioned below the renal veins, vascular isolation does not exist.

pared with the torrential hemorrhage seen from uncontrolled injuries of the large veins.

Technical Pitfalls

Despite the apparent simplicity of the technique, many problems with the use of the shunt can be encountered. If the initial hole in the chest tube is too close to the drainage holes, one of the fenestrations of the chest tube or the atrial drainage hole will be between the Rumel tourniquets, resulting in persistent massive hemorrhage from the site of the injury (Figs. 4 and 5). The only solution to this problem is to withdraw the shunt and correctly prepare another one. If the lower Rumel tourniquet is placed below the renal veins, vascular isolation will not exist (Fig. 6). Injury to the suprarenal vena cava may occur during attempts to surround it when exposure of the area is difficult. Excessive traction on the suprarenal vena cava may cause tearing of the lumbar veins at the origins of the renal veins. During insertion, the shunt may engage a laceration of the retrohepatic vena cava or suprahepatic vena cava causing additional damage (Fig. 7). If the vascular isolation achieved is perfect, a rare circumstance indeed, it is possible that a considerable amount of air may enter the hepatic veins and isolated vena caval segment. When this occurs, the lower Rumel tourniquet or Pringle maneuver should be released before completing the vascular suture line to ensure evacuation of the air.

The Pringle maneuver may be inadequately applied or become dislodged during required manipulations, and significant bleeding will persist. Another potential reason for failure of the Pringle maneuver is the existence of accessory or aberrant left hepatic arteries in about 25% of patients. These may not be included in the usual manuever. If inadequate hemostasis is encountered despite a well-positioned shunt and a secure Pringle maneuver, this possibility should be considered.

Alternatives and Controversies

The significant mortality rate associated with juxtahepatic vascular injuries treated with the atriocaval

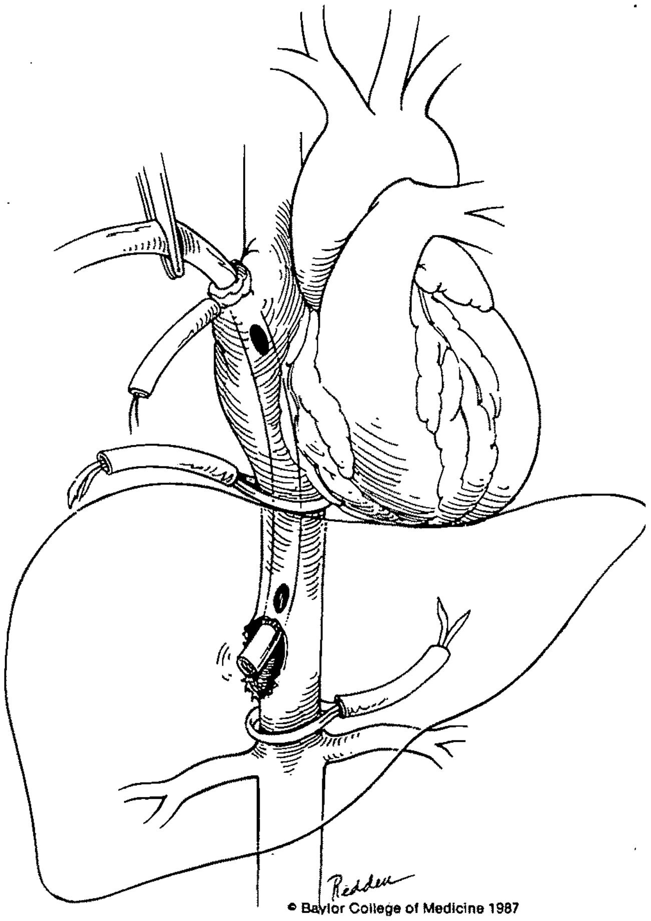

FIG. 7. During insertion, the surgeon should direct the shunt into the proper position and prevent the shunt from extending the venous injury.

shunt has provided a stimulus to find alternative techniques. One option is to use the hepatic parenchyma with intact capsule to tamponade the low pressure venous bleeding. This was successfully used in one patient in this series who would have otherwise required division of the liver to the level of the vena cava. This is not a unique recommendation, and others have used this method with success.[22] This technique is ideally suited for wounds where there is little destruction of the hepatic parenchyma. Great care must be taken in placing the sutures accurately and tying them gently. Another option is to achieve vascular isolation with occluding clamps on the vena cava above and below the liver after applying a Pringle maneuver and a clamp on the aorta. This concept was initially described by Heaney et al. and used by them in elective cases of hepatic resection.[23] The same approach has also been used for the treatment of trauma to the juxtahepatic vasculature in children.[24] In a similar fashion, occlusive balloon catheters have been used both experimentally,[25,26] and clinically.[2,26] Unfortunately, it has been our experience, as well as that of others,[3] that severely injured patients with significant hemorrhage and shock do not tolerate occlusive vascular isolation well.

Another alternative, appropriate for small injuries of the suprahepatic vena cava or retrohepatic vena cava that can be controlled with a finger, is to sew beneath the finger with a needle large enough to make the pass with one motion, and then apply gentle traction to the suture to aid in hemostasis. The remainder of the suture line is then completed while accepting the blood loss. Minor injuries of the retrohepatic vena cava exiting through or posterior to the caudate lobe may be controlled by dividing the left or right triangular ligament and rotating the lobe to the midline. Lobar rotation will aid in exposure of the injury as well as partially or completely occluding the retrohepatic vena cava. Patients may not tolerate this maneuver well, but if the injury is small, it may be the most expeditious way to control hemorrhage and repair the injury. In unusual circumstances, injuries may be exposed enough to grasp with a thumb forceps and secure with a partially occluding clamp.

A unique and bold approach is that of Pachter and co-workers.[9] After expressing disappointment of having only two of four survivors with the shunt, they developed a direct transhepatic approach. The essentials of this technique include: (1) the maintenance of posterior compression of the liver for hemostasis while correcting volume deficits; (2) the use of a Pringle maneuver for as long as is required to repair the injury; and (3) division of as much liver as is necessary, using finger fracture, to expose the injury and gain direct control. In a remarkable series of 10 patients with juxtahepatic vascular injuries, the first four were managed with a shunt and two survived. The next six consecutive patients were managed without a shunt and five of the six survived. The authors agree heartily with Pachter's emphasis on restoring lost volume, maintaining hemostasis, and an adequate duration of the Pringle manuever; however, this achievement may be a greater tribute to the skill of the surgeons involved than testimonial to the technique.

Conclusions

Extensive injuries to the juxtahepatic veins remain lethal injuries. The high mortality rate is due to profuse hemorrhage and severe shock produced by these injuries before the time vascular control can be attempted. The atriocaval shunt is not a perfect solution to the problem and difficulties with its use may occur; however, when the decision to use the shunt is made rapidly and hemostasis is maintained with vigilance, patients with otherwise irreparable injuries may survive. Hepatic resection should be assiduously avoided, and is not necessary only for exposure of the injury. Alternative shunting techniques, *e.g.*, use of a transatrial endotracheal tube, may help to overcome technical problems and improve survival in the future.

DISCUSSION

DR. J. DAVID RICHARDSON (Louisville, Kentucky): This paper represents another excellent contribution and presentation from the Houston group on the management of a difficult topic in trauma, and I certainly would recommend the manuscript by Drs. Feliciano, Burch, and Mattox to your attention. They have done an excellent job of outlining some of the real pitfalls that these patients present.

At issue is whether or not the atriocaval shunt is really necessary for juxtahepatic caval injuries or whether these injuries really could be repaired with similar results without the use of a shunt. With the use of an atriocaval shunt, we have treated 24 patients with retrohepatic or juxtahepatic caval injuries at the University of Louisville. Unlike the Houston group, 16 of our cases were due to blunt trauma, and only six were due to penetrating trauma.

Seven of these 24 patients were able to leave the operating suite alive. Three subsequently died of sepsis, coagulopathy or various other problems, and there were four long-term survivors. These results are not altogether dissimilar from those presented from Houston. Two of the four survivors had blunt trauma unlike the Houston group's series and two of our patients had penetrating injuries. In two of these cases in which I personally participated, the caval injuries were fairly small, and quite honestly, they could possibly have been repaired by direct suture technique or conventional techniques without the use of a shunt. However, I agree with the point the authors made, that is, once these injuries are recognized, you need to commit fairly promptly to either using the shunt or not, and we did choose that technique with success.

We have come to believe that prompt placement of the shunt, as has been indicated by the authors, before the development of coagulopathy is the key to its successful use, and, therefore, we try to move forward with prompt shunt placement as soon as we recognize the severely bleeding venous injury in the retrohepatic position that does not promptly respond to a Pringle maneuver.

Technically, we have found the endotracheal tube to be useful in that it obviates the need to encircle the inferior vena cava with its attendant technical complications. I think it is maybe a little bit tougher to cut that more proximal hole, but at least you don't have to deal with the distal cava in quite the same manner.

In our residency program, we have made liberal use of the fresh dissection lab which we developed in conjunction with the department of anatomy, and I think, quite simply, if you are going to try to teach residents to do that, you really can't do it with a bleeding, dying patient, and that the forethought of having gone through this a couple of times in the dissection lab is certainly one that I would commend to those of you who are involved in resident education or who might be an occasional operator in this area yourself.

In summary, we believe that the atriocaval shunt does have a place in these most difficult injuries, but that the very nature of the injuries themselves will always make the survival ability of these patients lower than would ordinarily be satisfactory. We will continue to use the shunt in these selected patients, however.

DR. LEON PACHTER (New York, New York): I would like to congratulate the Baylor group on their superb contribution to the management of juxta hepatic venous injuries employing an atriocaval shunt.

A recent review of 66 cases treated at major trauma centers in which atriocaval shunts were used revealed that only 15 patients survived for a mortality of 77%.

The authors were able to salvage 6 of 18 patients for a mortality of 67%, when patients with resuscitative thoracotomy were excluded. The lethal nature of this injury is quite evident.

Why has the mortality with atriocaval shunting been so high? First and foremost is the devastating nature of the injury itself, but in most series, failure of the atriocaval shunt was probably related to three key factors. First, delay in early recognition of the injury. Second, delay in shunt-insertion until all other methods have been exhausted to control hemorrhage. At this point, a coagulopathy exists and no matter what the surgeon does, the patient will most probably die. To insert a shunt at this time only will result in a bad name for the procedure. Three, lack of experienced personnel for expeditious shunt insertion. If these three factors are avoided as they were by the authors, then the devastating nature of the injury itself must be implicated as the eventual cause of death.

Given this fact, what then is the optimal method of managing these injuries? Atriocaval shunting no doubt will be the method of choice, but alternatives do exist.

We managed six consecutive patients at Bellevue Hospital without a shunt, employing the technique of prolonged portal triad occlusion up to 60 minutes and rapid finger fracture of normal hepatic parenchyma to get down to the site of vascular injury for primary repair. Five patients survived.

Clearly, there exists a group of patients that can be managed without a shunt.

In their manuscript, the authors themselves report 15 patients with retrohepatic caval injuries who were managed without a shunt. Seven of the 15 survived for a salvage rate of nearly 50%. The survival in this group of patients without a shunt is clearly somewhat better than the 67% reported in patients in whom a shunt was used.

I would appreciate the authors' commenting on the two groups and elucidating for us the criteria for either using an atriocaval shunt or not.

As no one institution has enough patients for statistically significant data, a larger series will be needed to set up guidelines as to which patients require a shunt and which patient can be managed without it.

I enjoyed the manuscript, and I am sure that it will be a landmark paper in the field of hepatic trauma.

DR. JOHN OCHSNER (New Orleans, Louisiana): Dr. Feliciano has shown us that this is really a devastating lesion, having an 81% mortality.

When I was a boy some 30 years ago in Houston, we researched our inferior vena cava injuries, and we had 48 inferior vena cava injuries. There were four patients with retrohepatic vena cava injuries. All four patients died, but two of them were not bleeding actively at the time of exploratory surgery, and it wasn't until we entered the hematoma that we got into the bleeding problem.

We suggested at that time that these areas be packed in an attempt to let this clot and to maintain an intact retroperitoneal space. In order to test this hypothesis, we went to the lab.

(Slide) We took a Himelstein valvulotome, inserted it through the common femoral vein of a dog, brought it up into the retroperitoneal space at the level above the renal veins, and this cut out an elliptical piece of vein and adjacent tissue. The instrument cuts out a section in the posterior aspect, leaving the peritoneum intact. (Slide) You can see the hemorrhage begin.

(Slide) Shortly thereafter, you see this massive hemorrhage. We did six dogs in this group. All of them survived. Then we sacrificed them a week later.

(Slide) And this is what you see: most of the blood has been absorbed. We opened the retroperitoneal space. (Slide) And one can see this elliptical incision of the vena cava that allowed the hemorrhage and yet allowed the clotting with the intact retroperitoneal space.

We then took another series of dogs to test whether we could make an incision into the inferior vena cava and then just make the retroperitoneal space intact. We did this by putting some buttress stitches as one sees here, taking a knife, a 15 blade, and incising the retroperitoneum and inferior vena cava. These buttress stitches are not into the cava but just into the peritoneum, and yet the retroperitoneum space controls the bleeding. Next, the dog is a sacrifice (Slide) a week later, showing a relatively small incision compared to the one in which a piece of tissue is taken with the valvulotone.

So we have pretty well proved that if one has an intact retroperitoneal space, with the low pressure in the hepatic veins and inferior vena cava at this level, one need not worry about the continued bleeding.

Now, since there was no evidence of duodenal injuries which would have required opening the retroperitoneal space I would like to ask the authors whether although there was a significant amount of concomitant injuries, could their patient have possibly been treated by allowing the retroperitoneal space to be maintained as an intact space?

Today with the advent of biological glue where we are able to control probably many of lacerations in the liver, I wonder if, in retrospect, Dr. Feliciano thought any of his patients could have been treated by a more conservative method of controlling the hemorrhage with tamponade.

DR. JOHN D. ASHMORE, JR. (Greenville, South Carolina): (Slide) That is a venacavogram made 6 weeks after a 23-year-old came in after turning his dune buggy over while racing.

As we opened the abdomen, it was obvious we had a serious hepatic injury, so without touching it, we went to a right thoraco-abdominal. He had avulsion of the retrohepatic cava, so we occluded above and below with clamps, and also used aortic occlusion at the diaphragm.

By the time we got through, we ended up putting in a 20 mm Dacron graft. It is about 4 cm long.

He, of course, had a rocky post-op course, but was discharged after about 4 weeks, and I had occasion to do a follow-up on him this summer.

He was admitted with a fractured pelvis. He was racing his speedboat and the throttle stuck. He said he had done 130 miles an hour, but down-home people tend to exaggerate. He, at least, fractured his pelvis when he did bail out of the boat.

I present this because there is still some question about Dacron grafts in the vena cava, and I did this cavogram in 6 weeks because in a series of dogs, just about all the grafts had some thrombi, and complete occlusion at 6 months. I was questioning whether or not he should be on chronic anti-coagulation. We did not anti-coagulate him, and as I say, he is still around 9 years later.

DR. ALFRED GERVIN (Richmond, Virginia): May I first congratulate Dr. Feliciano on his very nice presentation and thank him for providing me in advance with a copy of the 35-page manuscript.

The injury that the authors address, perforation of the retrohepatic portion of the IVC, is truly a dreaded situation in trauma, often leading to the demise of the patient and to the graying of the hair of even the most experienced trauma surgeon.

All surgeons have had some experience with this particular traumatic process, and I am delighted that we have before us today a rather extensive experience for review.

In this series from, the Ben Taub Hospital, there were 31 patients. Of all 31 patients, 11 were in full code arrest at the time of presentation to the emergency department and underwent the emergency department thoracotomy. All died.

Of the remaining 18 patients, six survived. If we closely scrutinize these survivors, several characteristics are evident. Number one, all had penetrating trauma.

At our institution we are one for twelve with caval shunting for patients with blunt trauma.

Number two, over one-half of your survivors were not in shock when they arrived in your emergency department. Therefore, these patients were in fairly good medical condition.

Number three, more than 70% of your patients had injuries only of the cava and not of the hepatic veins—perhaps a much less difficult injury to handle.

And four, no patient in your series with concomitant hepatic injury survived.

These data, therefore, motivate three questions.

Based on your experience (number one) should shunting even be attempted in patients who have undergone emergency room thoracotomy? Your mortality was 100%.

Number two, should shunting even be attempted in patients with concomitant major hepatic injury? Again, your mortality was 100%.

Number three, for these patients might not extensive abdominal packing provide a better chance for survival?

DR. ARTHUR J. DONOVAN (Los Angeles, California): Dr. Feliciano and his associates have importantly focused on the major unresolved problem and cause of mortality in hepatic trauma: hepatic vein and juxtahepatic venous injury. A number of years ago, we reported eight cases of such injury treated with a variety of techniques of vascular isolation: atrial shunt, infrarenal shunt, and multiple vascular occlusions as described by Heaney (*i.e.*, occlusion of the vena cava above and below the liver, a Pringle maneuver, and occlusion of the supraceliac aorta with a clamp or compression device). Four of the eight patients survived. Based on this clinical experience and the results of subsequent canine experiments, we concluded that multiple occlusive clamps were the preferable technique. We continue to believe that if vascular isolation is necessary, multiple occlusive clamps are the simpler technique and create a field that is dry enough for vascular repair. Aortic occlusion above the celiac axis is essential to prevent infradiaphragmatic flow when the suprahepatic cava is occluded.

Among 234 cases of hepatic trauma treated in the past 2 years, vascular isolation by multiple occlusive clamps was employed in four cases. This rate of vascular isolation is generally comparable to that reported by Dr. Feliciano. There were two survivors, one of whom underwent major hepatic resection. Despite resurgence of interest in packing, we are not convinced that it is effective in cases of the most severe hepatic vein and juxtahepatic venous injury. In closing, I would ask Dr. Feliciano to comment on whether he has utilized the technique of multiple occlusive clamps and on his experience with packing for major venous injuries. I fear that the nature of major hepatic vein and juxtahepatic venous injury is such that with currently available techniques, a continued high mortality will be experienced.

DR. JON M. BURCH (Closing discussion): Dr. Richardson, we have used the endotracheal tube in only a single case in this series. However, it does eliminate having to gain vascular control of the suprarenal vena cava, which, according to our experience, was a major source of technical difficulty. Avoiding this step may help improve results in the future.

We have also taken our residents to the dog lab and rehearsed the use of the shunt with them. I think that is an excellent suggestion for those of us with these facilities.

Dr. Pachter asked about the seven survivors with retrohepatic vena cava injuries who were mentioned in the study but in whom shunts were not used. In general, these patients had smaller injuries which usually could be occluded with a finger, were not as sick on admission, and did not require resuscitative thoracotomy with the frequency that those in our shunt series did. I am quite certain these are the reasons that those patients survived. It is also possible that the shunt might have benefited some of the patients in whom it was not used.

I agree completely with Dr. Ochsner's comments. Nonexpanding retrohepatic hematomas with an intact retroperitoneum ought to be considered similar to hematomas caused by blunt trauma to the kidney or pelvic bones, all of which are best left alone.

The senior author of this paper has venocavograms of two patients with penetrating injuries that show retrohepatic venous defects. One of these patients was not operated on and the other closed promptly after finding a small retrohepatic hematoma. Both patients survived.

Dr. Ashmore, we have not had to use a graft in the last 270 patients with vena caval injuries, but it is reassuring to see that patients can do well over a long period of time if such a graft is required.

Dr. Gervin, based on our experience, it is difficult to justify the use of a shunt in the circumstances you mentioned. However, this is a small series, and these injuries are always going to be rare. We have always operated under the supposition that unless we try to save such desperately ill patients, we will never succeed. Furthermore, for the individual patient who survives such an exotic injury, the survival rate is 100%. Therefore, we will persist in trying to use these techniques, including EC thoracotomy.

Packing is not an alternative to suture repair of large venous injuries. Our results, when that has been attempted, have been poor. These injuries must be repaired. Packing may be useful as an adjunct in patients who have coagulopathy, and was used successfully in one of the patients that Dr. Feliciano mentioned.

Dr. Donovan, I still marvel at the paper that you and Dr. Yellin wrote in 1971. We have tried the caval clamping technique which you have described. Our patients have not tolerated this procedure well. We have had the experience of trying this initially, with the patient experiencing cardiac arrhythmias and profound hypotension and having an unsuccessful outcome. Certainly there are patients who will tolerate this procedure, but we just don't know how to pick them, and that has been a source of great frustration.

DOHME

Only one H_2 antagonist controls pH for up to 12 hours on a single dose

PEPCID® I.V. (Famotidine, MSD) is indicated in some hospitalized patients with pathological hypersecretory conditions or intractable ulcers or as an alternative to the oral dosage forms for short-term use in patients who are unable to take oral medication.

The recommended dosage is 20 mg q12h. Dosing intervals may need to be prolonged or dosage reduced in patients with severe renal insufficiency (creatinine clearance <10 mL/min) to adjust for the longer elimination half-life of famotidine. PEPCID I.V. is contraindicated in patients who are hypersensitive to any component of this medication. The adverse reactions reported for PEPCID Tablets may also occur with PEPCID I.V. In addition, transient irritation at the injection site has been observed with PEPCID I.V.

A double-blind, placebo-controlled study[1] involving eight volunteer hypersecretor subjects. The pH of gastric aspirates was measured hourly for 12 hours following single intravenous doses. PEPCID I.V. maintained the mean gastric pH above 4.0 at all time points throughout the 12-hour period with one 20-mg I.V. dose.

TABLETS
Pepcid®
(Famotidine|MSD)
20 mg and 40 mg

ORAL SUSPENSION
Pepcid®
(Famotidine for Oral Suspension|MSD)
40 mg per 5 mL

INJECTION
Pepcid® IV
(Famotidine|MSD)
20 mg per 2 mL

Contraindications: Hypersensitivity to any component.

Precautions: ***General:*** Symptomatic response to therapy does not preclude the presence of gastric malignancy.

Patients with Severe Renal Insufficiency: Longer intervals between doses or lower doses may be needed in patients with severe renal insufficiency (creatinine clearance <10 mL/min) to adjust for the longer elimination half-life of famotidine (see Clinical Pharmacology and Dosage and Administration sections of Prescribing Information).

Information for Patients: The oral suspension should be shaken vigorously for 5-10 seconds prior to each use, and unused constituted oral suspension should be discarded after 30 days.

Drug Interactions: No drug interactions have been identified. Compounds tested in man include warfarin, theophylline, phenytoin, diazepam, aminopyrine, and antipyrine.

Carcinogenesis, Mutagenesis, Impairment of Fertility: In rats and mice given oral doses up to approximately 2500 times the recommended human dose for active duodenal ulcer, there was no evidence of carcinogenic potential, no evidence of a mutagenic effect, and fertility and reproductive performance were not affected.

Pregnancy: *Pregnancy Category B*—There are no adequate or well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Nursing Mothers: It is not known whether famotidine is secreted into human milk; however, it is secreted into the milk of lactating rats. A decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children have not been established.

Use in Elderly Patients: No dosage adjustment is required based on age but may be necessary in severe renal impairment (see Clinical Pharmacology section of Prescribing Information).

Adverse Reactions: The adverse reactions listed below have been reported during domestic and international clinical trials in approximately 2500 patients. In the placebo-controlled clinical trials, the incidence of adverse experiences with PEPCID Tablets, 40 mg at bedtime, was similar to that with placebo.

Incidence Greater than 1%: The following adverse reactions have been reported to occur in more than 1% of patients on therapy with PEPCID in controlled clinical trials and may be causally related to the drug: headache (4.7%), dizziness (1.3%), constipation (1.2%), and diarrhea (1.7%).

Causal Relationship Unknown: The following other adverse reactions have been reported in clinical trials. While a causal relationship could not be established for these infrequently reported events, causality cannot be excluded. *Body as a Whole*—Fever, asthenia, fatigue. *Cardiovascular*—Palpitations. *Gastrointestinal*—Nausea, vomiting, abdominal discomfort, anorexia, dry mouth, liver enzyme abnormalities. *Hematologic*—Thrombocytopenia. *Hypersensitivity*—Orbital edema, conjunctival injection. *Musculoskeletal*—Musculoskeletal pain, arthralgia. *Nervous System/Psychiatric*—Paresthesias; grand mal seizures (single report); psychic disturbances including depression, anxiety, decreased libido, hallucinations (single report); insomnia; somnolence. *Respiratory*—Bronchospasm. *Skin*—Alopecia, acne, pruritus, rash, dry skin, flushing. *Special Senses*—Tinnitus, taste disorder.

The adverse reactions reported for PEPCID Tablets may also occur with PEPCID Oral Suspension or PEPCID I.V.; in addition, transient irritation at the injection site has been observed with PEPCID I.V.

Management of Overdosage: There is no experience to date with deliberate overdosage. Up to 640 mg/day have been given to patients with pathological hypersecretory conditions with no serious adverse effects. In the event of overdosage, treatment should be symptomatic and supportive. Unabsorbed material should be removed from the gastrointestinal tract, the patient should be monitored, and supportive therapy should be employed.

Dosage and Administration: ***Duodenal Ulcer:*** The recommended adult oral dosage for active duodenal ulcer is 40 mg h.s.; most patients heal within 4 weeks, and it is rarely necessary to use the full dosage for longer than 6 to 8 weeks. A regimen of 20 mg b.i.d. is also effective. For maintenance therapy, the recommended oral dosage is 20 mg h.s.

Pathological Hypersecretory Conditions (e.g., Zollinger-Ellison Syndrome, Multiple Endocrine Adenomas): The dosage varies with the individual patient; the recommended adult oral starting dosage is 20 mg q6h, but some patients may require a higher starting dosage. Dosages should be adjusted to individual patient needs and continued as long as clinically indicated; up to 160 mg q6h have been administered to some patients with severe Zollinger-Ellison syndrome.

Oral Suspension: The Oral Suspension may be substituted for Tablets for those patients who cannot swallow tablets.

Directions for Preparing PEPCID Oral Suspension: Prepare suspension at time of dispensing. Slowly add 46 mL Purified Water. Shake vigorously for 5-10 seconds immediately after adding the water and immediately before use.

Stability of PEPCID Oral Suspension: Unused constituted oral suspension should be discarded after 30 days.

Intravenous Administration: In some hospitalized patients with pathological hypersecretory conditions or intractable ulcers, or in patients who are unable to take oral medication, the recommended intravenous dosage is 20 mg q12h. For preparation of solutions for injection or infusion and for compatible diluents, please see Prescribing Information. Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit.

Concomitant Use of Antacids: Antacids may be given concomitantly if needed.

Dosage Adjustment for Patients with Severe Renal Insufficiency: In patients with severe renal insufficiency (creatinine clearance less than 10 mL/min), the elimination half-life of famotidine may exceed 20 hours, reaching approximately 24 hours in anuric patients. Although no relationship of adverse effects to high plasma levels has been established, to avoid excess accumulation of the drug, the dosage may be reduced to 20 mg h.s. or the dosing interval may be prolonged to 36 to 48 hours as indicated by the patient's clinical response.

How Supplied: Tablets, containing 20 mg or 40 mg famotidine, with hydroxypropyl cellulose, hydroxypropyl methylcellulose, iron oxides, magnesium stearate, microcrystalline cellulose, starch, talc, and titanium dioxide as inactive ingredients, in bottles of 30 and unit-dose packages of 100; Oral Suspension, containing per 5 mL after constitution with 46 mL Purified Water, 40 mg famotidine, with citric acid, flavors, microcrystalline cellulose and carboxymethylcellulose sodium, sucrose, and xanthan gum as inactive ingredients, and sodium benzoate 0.1%, sodium methylparaben 0.1%, and sodium propylparaben 0.02% added as preservatives, in bottles of 400 mg famotidine for constitution; Solution for intravenous injection, containing 10 mg famotidine per mL, with L-aspartic acid 4 mg, mannitol 20 mg, and water for injection q.s. 1 mL as inactive ingredients, and benzyl alcohol 0.9% added as preservative to the multidose vial, as 10x2-mL single-dose vials and as 4-mL vials.

Charity Hospital Experience with Long-term Survival and Prognostic Factors in Patients with Breast Cancer with Localized or Regional Disease

CARL M. SUTHERLAND, M.D.* and FRANCES J. MATHER, PH.D.†

Long-term survival, the prognostic effects of race, age, tumor size, number of positive nodes, and presence of grave signs (fixation, peau d'orange/edema, dimpling/retraction, satellite nodules, and ulceration) in this distribution of estrogen receptors (ERs) and progesterone receptors (PRs) were studied in 2480 patients (1815 blacks, 665 whites) diagnosed with localized or regional breast cancer at Charity Hospital of Louisiana at New Orleans (CHNO) from 1948 to 1985 and followed up in the CHNO Tumor Registry. Breast cancer-specific survival rates were 57%, 45%, 41%, 39%, 38%, and 35% at 5, 10, 15, 20, 25, and 30 years, respectively. Size of tumor, clinical status of nodes, and degree of fixation were important prognostic clinical factors; and number of nodes was an important pathologic factor with no additional value of the "grave signs." Size and fixation were related. Independent of size, clinical and pathologic status and fixation were related. ER was related to age and PR was related to number of nodes. The excess mortality from breast cancer at later intervals from diagnoses was small compared with mortality from other causes. Some, but not all, clinical findings were important prognostic indicators. ER and PR were related to some variables with unclear meaning.

ALMOST ALL LONG-TERM SURVIVAL STUDIES following a diagnosis of breast cancer have shown early high mortality from breast cancer and some increased mortality from breast cancer at late intervals. The overall magnitude of mortality, however, has varied considerably among studies.[1-8] In addition, various interpretations regarding "cure" of the disease and its systemic implications have been given.

Pathologic lymph node and estrogen receptor (ER) and progesterone receptor (PR) status are important as prognostic factors for survival in patients with breast cancer.[9] ERs and PRs are important markers for hormonal responsiveness of tumor, they appear to affect overall prognosis, and have been reported to vary in presence and concentration by patient and tumor characteristics, particularly by race.[10] The variations by race are not completely understood. Age, race, year of diagnosis, size of tumor, clinical node status, and grave signs have not been identified consistently as prognostic factors in patients with breast cancer.[1-7,9,11-22] Recent studies are frequently on patients entered in clinical trials and are restricted to the stage of disease and characteristics of patients enrolled in that trial.[7,11] Few univariate or multivariable analyses of the prognostic contributions of these factors have been performed in patients more representative of the total population with breast cancer. That restriction and its results on multivariable analysis in breast cancer have seldom been discussed. Also, few, if any, recent studies on comparison of clinical characteristics alone, particularly in regard to the "grave signs" *versus* clinical characteristics plus pathologic number of nodes over several stages, have been performed.

The Charity Hospital of Louisiana at New Orleans Tumor Registry (CHNO-TR) has entered and collected follow-up information on patients with cancer since 1947. The patients in this study are those with regional (skin, chest wall, or muscle attachment and no evidence of distant metastases in accordance with Surveillance, Epidemiology, and End Results [SEER] definition) and localized (no evidence of complete or incomplete skin, muscle, or chest wall attachment in accordance with SEER definition) disease. This population of patients

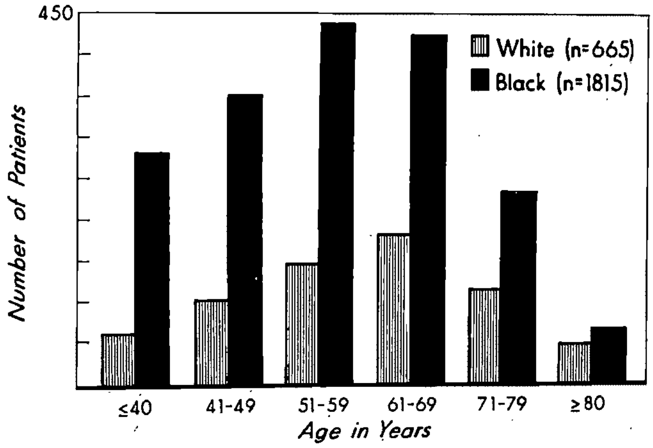

FIG. 1. Distribution of patients by age and race; all patients since 1948 (N = 2480).

with breast cancer is interesting because of its size (2480), length of follow-up (nearly 40 years for some patients), uniformly lower socioeconomic status, large proportion of black patients, and large proportion of patients with locally advanced disease. This study attempted to determine in these patients: (1) effect of breast cancer on long-term survival; (2) prognostic effect of age, race, year of diagnosis, size of tumor, clinical node status, presence of certain grave signs, and pathologic node status; (3) comparison of the prognostic effect of clinical findings alone to that of clinical findings combined with pathologic node status; and (4) the relationship of ER and PR status to other clinical and pathologic variables.

Patients and Methods

Inclusion Criteria

Included in this study were 2480 patients (1815 blacks, 665 whites), who met the following criteria: (1) enrollment and follow-up in the CHNO-TR between January 1, 1948 and December 31, 1981, from all services of Tulane University School of Medicine (T), Louisiana State University School of Medicine (L), and an Independent Service (no longer active) (I), follow-up information on I and T patients only, 1982 through 1985, and new patient entry on T patients only from 1982 through 1985; (2) diagnosis made at CHNO of malignant breast cancer without evidence of distant metastases, including positive supraclavicular nodes excluded from this study at first diagnosis; (3) either a single breast primary or the first of two or more breast primaries; (4) female of known race; (5) sufficient information available on diagnosis to establish stage of disease; (6) diagnosis was not an incidental finding at autopsy; and (7) no previous diagnosis of cancer. Of the 3443 potential tumors, 963 were excluded from analysis: 611 because the initial diagnosis was not made at CHNO, 197 because the tumor was not the only primary or the first of two or more primaries, eight because the tumor was not considered malignant by CHNO standards, three because the race was unknown, 118 because the patients were diagnosed from 1982 through 1985 and had an L number, 24 because the sex was male or unknown, and two because they did not have sufficient information for diagnosis of stage.

Age and Race Distribution

Figure 1 shows that the majority of patients in all age groups were black. The distribution by race was fairly similar at all ages, except in the older age categories where some decline was noted in the ratio of blacks to whites, probably reflecting the referral patterns of patients to CHNO.

Pathology

All patients with a diagnosis of invasive carcinoma were included. Those with other cancers of the breast, including sarcoma and noninvasive carcinoma, were excluded.

Type of Primary Therapy

The primary course of treatment in these patients was surgery only (43%); surgery and radiation (31%); surgery and chemotherapy (11%); radiation only (4%); and other treatments, including chemotherapy, hormonal treatment, and no surgery or radiation (11%). In all, 9% of the patients did not have surgery.

Classification by Cause of Death

All deaths were classified by the CHNO-TR according to status at death as follows: (1) no evidence of primary cancer (32%); (2) no evidence of primary cancer, but another cancer present (3%); (3) primary cancer present (62%); and (4) cancer status unknown (3%).

Lost to Follow-up

Of the patients not known to be dead, who were diagnosed during 1948 through 1985, 85% were contacted within the last 2 years; of those diagnosed during 1968 through 1985, 95% were contacted within the last 2 years.

Statistical Analysis

Survival curves were computed by means of actuarial methods in the BMDP series of computer programs (BMDP1L).[23] Breast cancer-specific curves were obtained by treating deaths resulting from causes other than breast cancer (CHNO-TR definition: no evidence of primary cancer or no evidence of primary, but another cancer present or cancer status unknown) as censored. Significant differences between survival curves were tested, using the generalized Savage (Mantel-Cox) test.[23] Cox's regression model[24] was used to evaluate the contribution of prognostic factors (BMDP2L).[23] Hazard rates for deaths from other causes were obtained from actuarial life tables (BMDP1L),[23] with deaths from breast cancer treated as censored.

Expected deaths were computed by adding the contributions of female age-, race-, year-, and breast cancer-specific death rates for the Louisiana population applied to individual follow-up times. These rates were obtained from Louisiana decennial population counts and deaths reported by the Department of Vital Statistics of the United States and the Louisiana Department of Health and Human Resources—Vital Statistics. The expected deaths were expressed as a proportion of this study population to provide an expected death rate for comparison.

The effect of prognostic variables in the multivariate Cox analysis was evaluated by means of the log likelihood test; *i.e.*, the quantity 2(LL[full model, df = kl] − LL [partial model, df = k2]) is distributed as chi-square with k1–k2 degrees of freedom.[25]

Degree of fixation was represented by two dummy variables (T_1 and T_2), both coded (0, 0) to represent the background group of no-fixation, incomplete (0, 1), and complete (1, 0). The relationship among degree of fixation, tumor size, clinical status, and number of nodes was investigated by means of log linear modelling (BMDP4F).[23,26] The relationship between the square root of ER and PR status and other prognostic variables was investigated by means of linear regression (BMDP2R).[23,27] The square root of ER and PR was used as a normalizing transformation on the skewed distribution of these variables.

Results

Breast Cancer-Specific Survival

Survivorship of all patients (combined localized and regional diseases, N = 2452), with other causes of death removed, illustrated the initial high mortality caused by breast cancer in the first 5 years after diagnosis, declining in mortality in the second and third 5-year periods, and little mortality after 15 years. The breast cancer-specific survival rate was 57%, 45%, 41%, 39%, 38%, and 35% at 5, 10, 15, 20, 25, and 30 years, respectively (Fig. 2). The survivorship of patients classified with localized (N = 1167) or regional (N = 1285) disease is shown in Figure 3. The survival pattern was similar among patients with localized disease: 74%, 65%, 61%, 57%, 56%, and 53% at 5, 10, 15, 20, 25, and 30 years, respectively, and regional disease: 40%, 28%, 24%, 23%, 22%, and 20% at 5, 10, 15, 20, 25, and 30 years, respectively, although of more magnitude in regional disease.

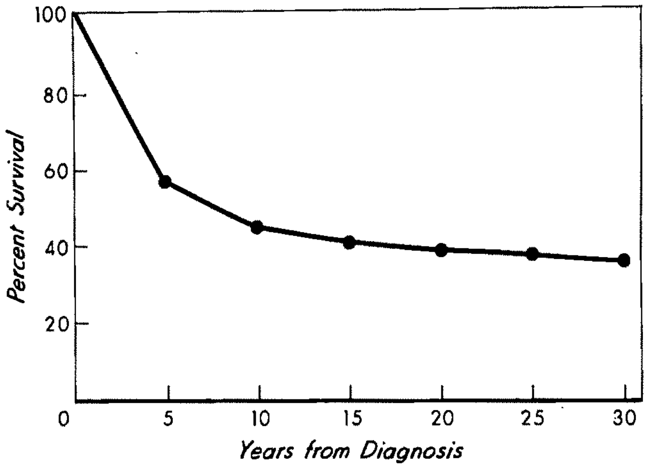

FIG. 2. Breast cancer-specific survival; all patients since 1948 (N = 2452).

After 1968, pathologic node status was recorded on a majority of patients. The effect of nodal status among patients with localized disease compared with regional disease is shown in Figure 4. The 5-, 10-, and 15-year survival rates of patients with localized node-negative disease (N = 275) were 85%, 75%, and 66%, respectively; with localized node-positive disease (N = 168), 59%, 44%, and 37%, respectively; and with regional disease (N = 379), 46%, 33%, and 29%, respectively.

The improved survival from breast cancer given survival to 5 years is shown in Figure 5. The survival rate from breast cancer only to 10 and 15 years, conditional on survival to 5 years, was 88% and 78% among node-

negative patients with localized disease, 75% and 63% among node-positive patients with localized disease, and 72% and 63% among those with regional disease.

Annual Hazard Rates

In calculating the annual breast cancer-specific hazard rates, initial high mortality rates were found in the first 5 years, decreasing to lower levels over time. The effect of competing risks or other causes of death in this population varied with age. Among patients over 65 years of age, the risk of death from other causes exceeded that from regional breast cancer by 10 years from diagnosis, and from localized breast cancer by 5 years from diagnosis. Among patients 50–65 years of age, the risk of death from other causes exceeded that from regional disease by 12–15 years, and from localized disease by 10 years from diagnosis. In patients less than 50 years of age, the risk of death from other causes did not exceed the risk from regional breast cancer from 17 to 20 years from diagnosis, and in localized breast cancer from 10 to 15 years. The risk of death from breast cancer in this population always exceeded that in the general population of comparable age and race (Fig. 6).

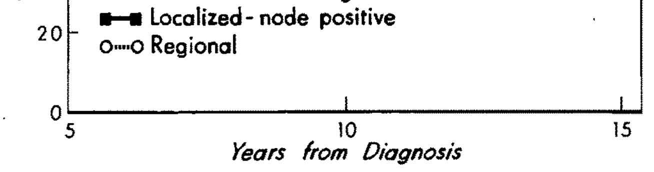

FIG. 5. Breast cancer-specific survival given survival to 5 years; all patients since 1948 by stage (N = 356).

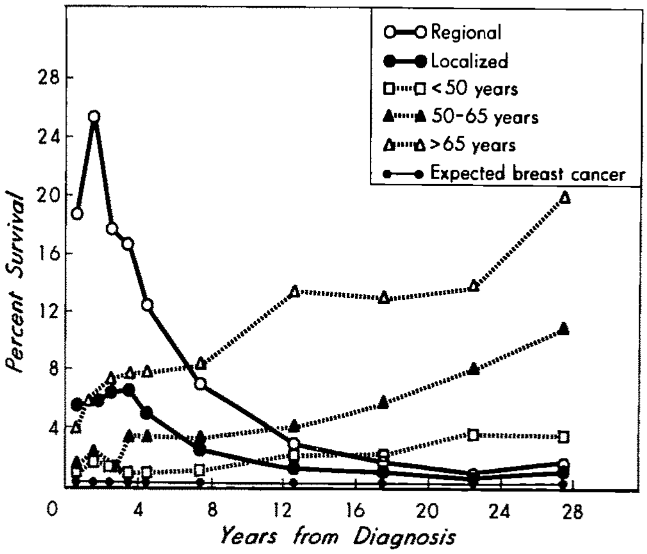

FIG. 6. Annual breast cancer-specific hazard rate by stage and other cause hazard rate by age; all patients since 1948 and the expected breast cancer-specific general population hazard rate (N = 2452).

Univariate Assessment of Prognostic Factors

The effects of several variables believed to be of prognostic significance were evaluated in a univariate analysis by means of the Cox proportional hazard model. Number of positive nodes, increasing size of tumor, degree of fixation (complete > incomplete > none), presence of ulceration, edema, peau d'orange, dimpling/retraction, positive clinical status of nodes, and earlier year of diagnosis were all associated with increased hazard of death caused by breast cancer. Only age at diagnosis, presence of satellite nodules, and race were not associated with the hazard caused by breast cancer (Table 1).

TABLE 1. *Univariate Assessment of Prognostic Factors*

Clinical Variables	p Value
Number of positive nodes (0–38)	0.00
Size of tumor (<1 cm to 8 cm or more)	0.00
Fixation (none, incomplete, complete)	0.00
Ulceration (present, absent)	0.00
Edema (present, absent)	0.00
Peau d'Orange (present, absent)	0.00
Dimpling/retraction (present, absent)	0.00
Clinical status of nodes (negative, positive)	0.00
Year of diagnosis (68, 69 . . . 85)	0.04
Age at diagnosis (21 . . . 94)	0.71
Satellite nodules (present, absent)	0.74
Race (black, white)	0.84

Multivariate Assessment of Prognostic Factors

Evaluation of Prognostic Significance of Clinical Signs. The effect of clinical factors—size of tumor, clinical status of nodes, and degree of fixation (complete *vs.* none and incomplete *vs.* none)—in comparison to several controlling factors also included in the model (race, age, and year of diagnosis) were evaluated in a multivariate model. Increasing size of tumor, positive clinical status of nodes, and degree of fixation (complete and incomplete) were all significantly related to increasing hazard of death caused by breast cancer. Neither age at diagnosis, race, nor year of diagnosis was significantly associated with the hazard of death resulting from breast cancer in this population (Table 2). A further analysis attempted to assess the importance of any interactions between the clinical variables: (1) size and clinical status, (2) clinical status and fixation, or (3) size and fixation. Neither of the first two interactions contributed significantly to the hazard. When the third term (size by fixation) was included in the analysis, however, the interaction was nearly colinear (closely related) with terms already in the model. Thus, it was impossible to evaluate the joint effect of these variables on survival.

The effect of clinical status of nodes and degree of fixation on survival is seen in the 5-year survival rates in Table 3. The mean size of tumor was similar between negative and positive clinical status within a fixation group. The mean size of tumor did, however, increase with degree of fixation (Table 4).

Evaluation of Prognostic Significance of Grave Signs. Effects of grave signs, ulceration, peau d'orange, satellite nodules, dimpling/retraction, and edema were evaluated by comparing two models: one containing grave signs and the current model variables such as age at diagnosis, race, year of diagnosis, size of tumor, clinical status of nodes, and degree of fixation (complete fixation *vs.* none and incomplete fixation *vs.* none) to control for known clinical prognostic factors *versus* the current model containing only the clinical prognostic factors. No significant effect of any grave signs was detected after controlling for known clinical factors (chi-square = 2 (−1631 − [−1634]) = 6, 5 df, $p > 0.3$).

TABLE 2. *Cox Proportional Hazard Analysis of Clinical Prognostic Factors*

Variable	Coefficient	Standard Error	Coefficient/ Standard Error	Relative Risk
Race	−0.069	0.178	−0.4	0.93
Age at diagnosis	−0.009	0.005	−1.8	0.99
Year of diagnosis	−0.018	0.017	−1.0	0.98
Size of tumor	0.103	0.030	3.4*	1.11
Clinical status	0.767	0.135	5.7*	2.15
Complete fixation (T_1)	0.662	0.173	3.8*	1.94
Incomplete fixation (T_2)	0.458	0.166	2.8*	1.58

Coding: race (0-white, 1-black); age at diagnosis in years (21 . . . 94); year of diagnosis in years (68 . . . 85); size of tumor (1 . . . 8, 9 cm or more); clinical status (0-negative, 1-positive); complete fixation (0-no, 1-yes); incomplete fixation (0-no, 1-yes).

Evaluation of Prognostic Significance of Pathologic Node Status in Addition to Clinical Signs. The effect of pathologic node status was evaluated by adding it to the current model containing the clinical signs and age at diagnosis, race, and year of diagnosis. The number of positive nodes was significantly associated with increasing hazard. Further, in an analysis of interaction terms, only fixation by pathologic node status was included, suggesting that the effect of number of positive nodes and degree of fixation on the hazard resulting from breast cancer were slightly less among those with incomplete and complete fixation compared with the no-fixation group (Table 5).

The decreasing survival with number of positive nodes, degree of fixation, and clinical status of nodes is illustrated by 5-year survival rates in Table 6. Association of size with fixation is shown, as is the lack of relation between size and number of nodes and clinical status (Table 7).

Relationship Between Size, Pathologic Nodes, Clinical Status, and Fixation

Some relationship was expected among size of tumor, nodes, clinical status, and degree of fixation. Degree of

	Fixation					
	None		Incomplete		Complete	
Clinical Status	Mean Size of Tumors	No. of Patients	Mean Size of Tumors	No. of Patients	Mean Size of Tumors	No. of Patients
Negative	3.9 ± 0.1	340	4.9 ± 0.3	59	5.9 ± 0.3	64
Positive	4.4 ± 0.2	100	4.7 ± 0.3	66	6.6 ± 0.3	60

fixation was related to size of tumor (no fixation with smaller tumors, incomplete fixation with larger tumors, and complete fixation with the largest tumors) (Fig. 7). Clinical status had no effect on size of tumor beyond degree of fixation (possibly a trend in the complete fixation group) (Fig. 8), nor did the nodal status have any effect (Fig. 9) except slightly in the group with no fixation (Fig. 10).

Independent of size, however, a complicated relationship existed between the number of positive nodes, degree of fixation, and clinical status. An increased number of positive nodes was observed for clinically positive patients relative to clinically negative patients among those with incomplete or no fixation. In the group with complete fixation, however, little difference was observed between those with clinically positive or negative nodes with respect to number of positive nodes (Fig. 11).

Estrogen Receptor (ER) and Progesterone Receptor (PR) Status Relationship to Other Variables

The ER (N = 54) status and PR (N = 52) status have been collected since 1981. The relationship between these hormonal variables and race, age, number of positive nodes, clinical status, size, and fixation was investigated (Table 8). ER status increased with age ($p < 0.001$) and lower ER with clinically positive node status was observed ($p < 0.025$). No evidence existed that race, number of positive nodes, size, or degree of fixation was related to ER. In a multivariate evaluation, ER increased with age ($p < 0.001$); however, the relationship between ER and clinical status of nodes was of borderline importance ($0.05 < p < 0.10$). Tumor size, race, number of positive nodes, and degree of fixation were not related to ER status (Table 9). The relationship between PR status and prognostic variables was examined by univariate methods (Table 10). PR was found to increase with number of nodes ($p < 0.05$). No relationship was observed between PR and race, age, size of tumor, clinical status, and degree of fixation. In a multivariate analysis, the same findings were observed (Table 11).

Discussion

Long-term Survival

An excess of deaths from breast cancer was found in this study at all time intervals: large at early follow-up times, declining at later follow-up times. This finding is similar to that documented in most other long-term studies; *e.g.*, the hazard rate in the first 5 years from death caused by breast cancer in this study was similar to that from all causes reported by Langlands et al.[1] At later time intervals, however, comparison was not appropriate because of the difference in definition of hazard.

TABLE 5. *Cox Proportional Hazard Analysis of Clinical and Pathologic Node Prognostic Factors*

Variable	Coefficient	Standard Error	Coefficient/ Standard Error	Relative Risk

	4^+	0.41 ± 0.08	41	0.32 ± 0.08	40	0.24 ± 0.10	21

As the hazard rate from breast cancer declined at later intervals, the hazard rate from other causes increased because other causes were primarily a function of the increasing age of the patient and, to some extent, race or socioeconomic status, and date of diagnosis, among other mortality risk factors.

Several studies[2,5,7] reported that 75–85% of all deaths that occurred in the breast cancer population studied were caused by breast cancer. Some may interpret this as the probability of eventual death resulting from breast cancer. Our study, restricted to regional and localized disease, reported 62% of all deaths with breast cancer. The probability of patients eventually dying of breast cancer remains a function of: (1) death caused by breast cancer, which depends on the prognostic factors at time of diagnosis such as stage of disease and number of nodes, and (2) deaths resulting from other causes, which depend on age, race and/or socioeconomic status, and date of diagnosis. The ratio of breast cancer deaths to total deaths is, thus, confounded by these factors and is not a measure of the probability of patients eventually dying of breast cancer. Estimation of the risk of eventual death from breast cancer should be computed by life-table methods, based on prognostic factors at diagnosis of breast cancer and other causes of death.

Several authors[1–6,8] have discussed the results of long-term studies in relation to "cure" and breast cancer as a systemic disease. The discussions are based on a population definition of cure to evaluate the efficacy of cancer treatment. The concept is attributed to Greenwood (cited in Lee,[28] who stated: "If an examination of the after histories of such patients showed that on the average they lived as long as a random sample of persons in the same age, sex, occupation, etc., nobody could object to the use of the word 'cure.' " (p. 96).

Almost all studies show an excess in breast cancer deaths over that expected in the general population. This excess of deaths may be interpreted by some as evidence, by the above definition, that the breast cancer population is not cured. The methodologic issues that may be responsible for the excess, such as distribution of other causes of death in the reference population and breast cancer population and difficulty in allocation of deaths by cause,[29] is discussed elsewhere. We believe there is little reason to interpret this excess mortality as an indication of incurability or presence of systemic disease in the total breast cancer population. Regardless of interpretation, the excess is small at late intervals, particularly in relation to deaths from other causes.

Prognostic Factors

In previous studies of prognostic factors in this patient population when patients where classified by clinical

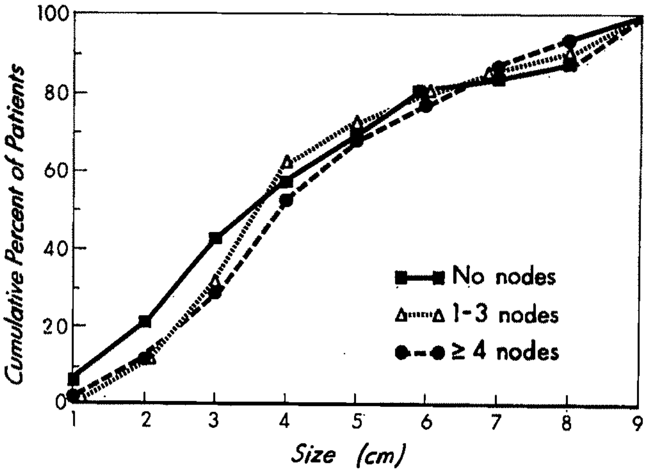

FIG. 9. Tumor size by pathologic node status without regard for degree of fixation or clinical status (N = 615).

stage into regional[30] and localized[29] disease, a weak relationship was found between size and prognosis, a finding in general agreement with other studies with similar patient populations.[11,15,17,19-22] This study found an overall effect of tumor size on breast cancer-specific survival. In addition, a relationship of size to fixation was found. These findings may be explained as follows: when the patient populations are restricted by stage or other characteristics, prognostic factors also restricted by this classification may not appear as significant.

The relationship of increasing number of nodes to decreasing survival and increasing percentage of pathologically positive nodes with clinically positive status has been well documented. In this study, we found an independent additional effect of clinical status on survival (decreasing survival with clinically positive status) after controlling for number of pathologically positive nodes.

The relationship between size, fixation, clinical status, and number of nodes needs clarification. Clinical observation and some studies have found increased size was related to increased number of nodes[17] and, one would expect, with being clinically positive. When fixation was not controlled, this relationship was found. When the population was classified by fixation, no clinically significant relationship between size and pathologic nodes or size and clinical status was observed. Within each fixation group, the distribution of tumor size was independent of number of nodes and clinical status; however, because tumor size was related to degree of fixation, a correlation between tumor size and clinical status or pathologic nodes was found when fixation was not controlled.

The lack of prognostic importance of the traditional grave signs is in accordance with some other studies.[19-22]

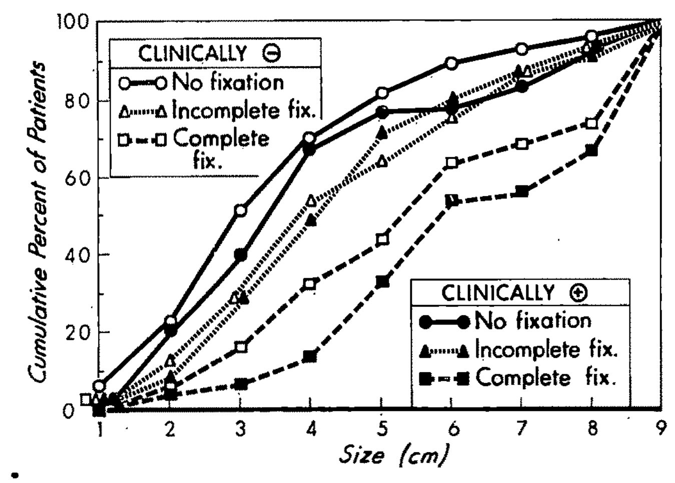

FIG. 8. Tumor size by clinical status and degree of fixation without regard for pathologic node status (N = 615).

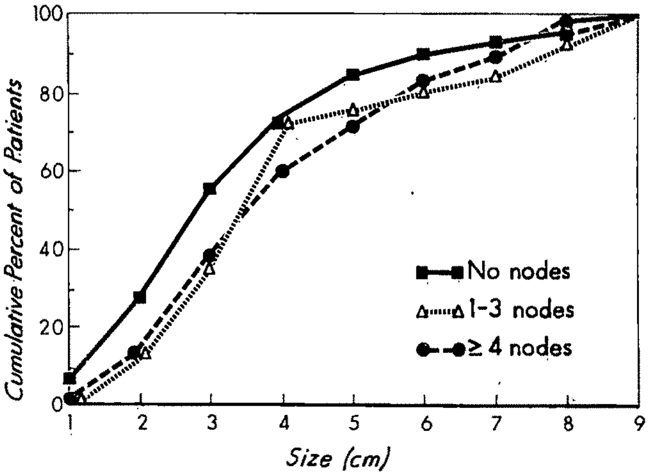

FIG. 10. Tumor size by number of pathologic nodes in patients with no fixation without regard for clinical node status (N = 378).

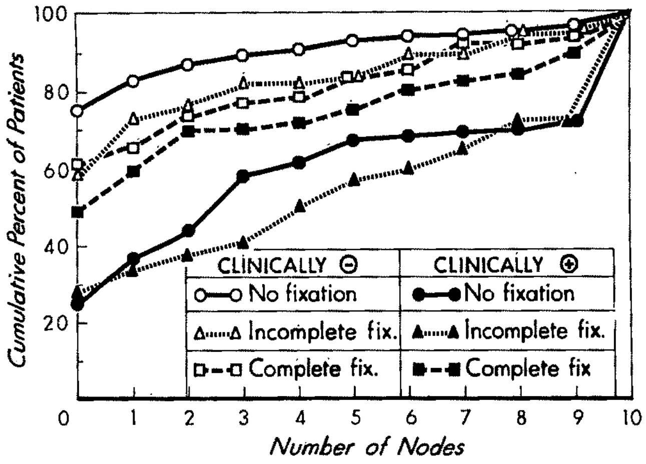

FIG. 11. Number of pathologic nodes by clinical status of nodes and fixation without regard for size (N = 615).

TABLE 9. *Multivariate Assessment of Estrogen Receptor and Prognostic Variables*

Prognostic Variables	p Value
Age	<0.001
Clinical status of nodes	$0.05 < p < 0.10$
Tumor size	>0.25
Race	>0.25
Number of positive nodes	>0.25
Degree of fixation	>0.25

The grave signs may be ignored when predicting survival if size, fixation, and clinical status are known.

Any study of prognostic factors is subject to the unknown bias caused by lead-time (the time from first possible diagnosis to actual diagnosis) differences. This patient population contains a significant number of women in whom tumors have been present for long periods. Multiple factors send women to health care facilities for a diagnosis. Some women refer themselves at the first possible finding of a small lump in the breast, whereas other breast cancers are found at admission to the hospital for other causes. Some patients are admitted when the symptoms of metastatic disease or localized problems are intolerable. The bias of varying lead times on the identification of prognostic variables in cancer is unknown, but probably affects findings.

The complete axillary node dissection is not without its complications. How important is an axillary node dissection for prognostic information in care of the patient population? With current interest in perioperative adjuvant therapy, clinical trials may be developed in the near future in which therapy other than surgery may be delivered first and, thus, axillary lymph node status will be unknown. How well can prediction of survival be made on the basis of clinical factors alone? We studied the additional contribution of pathologic node status as a prognostic factor beyond clinical factors alone and found in patients with incomplete or no-fixation that prognosis depends on pathologic node involvement. Among those with complete fixation, survival depends on clinical status of nodes. Whether an axillary dissection should be performed for prognostic information depends on: (1) if a variation exists in prognosis by axillary node status, and if it does, whether this knowledge can be used to select a treatment that will improve survival; and (2) if the proportion of patients misclassified can be justified. As one gets to larger tumors with increased fixation, the differences in breast cancer-specific survival are far less by axillary node status, and dissection of the axilla may not be necessary for prognostic information. In the best prognostic group of patients (66) with tumors less than 2 cm, no fixation, and clinically negative axilla, a 12% (8/66) rate of pathologically positive nodes was found. Whether an axillary node dissection is necessary to find the 12% of patients is a function of the above criteria.

As in our previous studies[29,30] we found no relationship of age and race to survival. This finding of no difference by age and race is at variance with some other studies and popular clinical belief.[7,12-16] Our previous studies found no relationship of race to survival in this fairly uniform low-socioeconomic group of black and white patients and noted that another study[31] found no differences in survival by race when socioeconomic status was controlled, suggesting that differences in survival by race were due primarily to differences in socioeconomic status rather than race.

Estrogen Receptor (ER) and Progesterone Receptor (PR) Relationships

Because ER and PR values have been collected only since 1981, the follow-up time on the patients is too

TABLE 8. *Univariate Assessment of Estrogen Receptor and Prognostic Variables*

Race	>0.25

TABLE 11. *Multivariate Assessment of Progesterone Receptor and Prognostic Variables*

Prognostic Variables	p Value
Number of nodes	<0.05
Age	>0.25
Fixation	>0.25
Tumor size	>0.25
Clinical status	>0.25
Race	>0.25

short to make any statement regarding the relationship of ER and PR to survival. Our findings of no relationship of ER to size and number of nodes, and increasing proportion of ER and increasing concentration of ER with increasing age, are in general agreement with other studies.[10] Our finding of no relationship with race is consistent with some and not with others,[10] but is consistent with our previous findings of no differences in any variable studied by race in this breast cancer population.

Our finding of a possible relationship between ER and clinical node status, to our knowledge, has not been confirmed by other studies. That decreasing ER may be related to positive clinical node status and positive clinical node status is related to decreased survival is in keeping with the idea that negative ER is related to tumor differentiation with decreased differentiation related to decreased survival.

Of interest is the increasing ER with increasing age, but no relationship of increasing age to survival. This finding suggests that properties of ER are related to age separate from their relationship to survival.

The relationship between PRs and other patient and tumor characteristics has not been reported as extensively as that of ERs. This study found no relationship between PRs and any factors other than increasing number of pathologic nodes. These data seem unusual, in that an increasing PR level was found to be related to increased survival by Clark et al.[9]; however, it is also of interest that Clark's study found survival was decreased in those patients for whom PR information was known over those not known. Fisher et al.[32] reported no relationship of PR to number of nodes in a group of axillary node-positive patients with a different type of analysis, and Fisher et al.[33] reported a weak relationship of PR+ to 1 to 3 nodal metastases as opposed to 4+ in a subset of the same patients. The relationship between our findings, those of the above authors,[9,32,33] and the overall distribution and significance of PRs remains unclear.

Some care should be taken in interpreting the relationship of ER and PR because of the selection process in obtaining these values. Tumors too small to be assayed are not included; thus, the relationship of other variables to ER and PR are conditional on this selection process.

Acknowledgments

The authors thank Charity Hospital of Louisiana at New Orleans (CHNO), the CHNO Tumor Registry, the Department of Surgery of Louisiana State University School of Medicine, and all CHNO faculty, staff, and house staff involved in the care of these patients, Gae O. Decker-Garrad for manuscript preparation, and Winifred Hunter for typing.

DISCUSSION

DR. EDWARD M. COPELAND III (Gainesville, Florida): Dr. Sutherland asked me if I would discuss this paper, and I am very happy to do so.

Kirby Bland and I were asked to review the papers on breast diseases presented at the Southern Surgical Association meetings for the last 100 years. I will have the pleasure of presenting this material to you later in the program, but there are some slides that I will not be able to include in that report. I thought you might now enjoy seeing those that deal with prognostic indicators for breast cancer.

(Slide) This slide is from a paper given by Burton J. Lee of New York in 1932. It shows that regardless of which quadrant of the breast the cancer arose from, the three-year survival rate was the same. Lee also gets credit for having pointed out that axillary metastasis is the most important prognostic indicator for breast cancer.

(Slide) In 1956, Drs. Alrich, Liddle, and Morton of Charlottesville also evaluated the quadrant in which the cancer arose as a prognostic variable and found the percentage of patients with axillary metastasis and the five-year survival to be the same regardless of the quadrant of origin.

(Slide) This slide is from a paper by Nicolson and Grady given in 1947. The patients were from the Steiner Breast Clinic in Atlanta. The data shown indicate that as the size of the breast cancer increases in diameter, the five-year survival rate decreases. Thus, in 1947 (actually even before that time), the size of the lesion was recognized as a major prognostic indicator.

(Slide) Stewart Harrington gave several presentations before the Southern Surgical Association between 1946 and 1952. He reviewed the radical mastectomy data from the Mayo Clinic. This slide is of 8,563 patients followed for up to 30–45 years. Positive lymph nodes occurred in 63.7% of the patients, whereas 36.3% had negative nodes. All deaths were assumed to be from malignant disease, and even at the 30–45 year interval, 14% of the patients with negative nodes were still alive. This data from 1952 questions whether or not breast cancer is always a systemic disease since lengthy survival was obtained with surgery as the only modality of therapy.

(Slide) In 1961, associated pregnancy as a prognostic variable was evaluated by Byrd and Stevenson of Nashville. Overall, five-year survival was 55.2% for 29 patients. Patients with positive nodes had a 28% five-year survival, whereas 11 patients with negative nodes had a 100% five-year survival. This data showed that pregnancy *per se,* when associated with negative axillary lymph nodes, was not a poor prognostic indicator.

(Slide) In 1960, similar data on pregnancy was demonstrated by Horsley and Alrich of Charlottesville. All patients with negative nodes and associated pregnancy survived for the five-year interval.

I would like to ask Dr. Sutherland about two therapeutic points, since he has reviewed a large number of patients from Charity Hospital treated over a lengthy period of time. Did either radiation therapy or the type of surgical procedure done affect long-term survival?

DR. LOREN J. HUMPHREY (Shawnee Mission, Kansas): I wish to thank Dr. Sutherland for affording me the opportunity of reviewing this manuscript.

This paper brings forth new data and some invaluable contributions as an extension of initial studies reported previously from the Charity Hospital, New Orleans Tumor Registry, and, indeed, by Dr. Sutherland himself.

Allow me to initiate my comments, if you will, by making an observation that, while seeming tumidic, might otherwise be lost in this sea of data, which you will notice when you read the manuscript.

The data—culled by several surgeons (and at least two teaching services) from the tumor registry comprising patients' results—stands as a witness to the great value of that instrument called the tumor registry. For those of us who have worked for many years in the Cancer Commission of the American College of Surgeons, and for the college, insisting on the exigency for maintaining a tumor registry in cancer program approvals, this paper is a reward for our perseverance. The large number of patients with excellent long-term follow-up data only as seen in tumor registry data is the backbone of this paper. The plethora of data and its univariate and multivariate analysis is a real contribution. These data and their analyses should strike the death knell for some all-too-popular misconceptions. Indeed, when I study and ponder over this, I can only use one or two as an example.

First, Dr. Sutherland has shown that not all breast cancer patients die of breast cancer. Indeed, by 30 years, 36% of those were still surviving. "Therapeutic nihilism"—I wonder where it has gone when we realize that. I urge you to study this paper in detail and discern the many interrelationships of size, nodal status, and grave signs to prognosis.

I would highlight this by asking Dr. Sutherland: Considering the seeming independence of certain variables on survival, can you then attribute this effect to biologic behavior of certain tumors? For example, the survival of clinically negative patients with fixation is almost the same as clinically node positive patients without fixation.

Finally, prompted by the current trend toward conservative treatments of breast cancer and their attendant high local recurrence rate, I wonder: Will you be able to continue these studies by applying your multivariate analysis to risk of local recurrence, its subsequent treatment and the survival therefrom?

DR. ROBERT M. BEAZLEY (New Orleans, Louisiana): Thank you, Ted. In reviewing 2480 patients from the Charity Hospital in New Orleans tumor registry, the authors have reaffirmed the observation that tumor size and nodal status are key prognostic features of breast cancer. I think the "therapeutic nihilism" that this is not a curable disease has been fostered on us by our medical oncologist colleagues, and this information does to a large measure put that to rest.

It would have been of interest to evaluate some of the recently described prognostic factors such as cellular differentiation, tumor necrosis and tumor markers, particularly in the long-term survivors to see their predictive value.

I have one question for the authors, and that is, in your 1985 publication, using some of the same patients, you concluded that nodal status and peau d'orange were statistically the most important prognostic factors in long-term survival. In view of your presentation here, peau d'orange does not seem to carry the same precedence, and I wonder if you have any comments on that?

Finally, I would like to congratulate Dr. Sutherland on his election to membership and a well presented paper. However, I would be remiss if I failed to express my disappointment in his failure to heed our expressed wish that he not include the LSU patient data from the Charity Hospital Tumor Registry in his paper.

DR. JOHN D. PIGOTT, JR. (Memphis, Tennessee): Congratulations to Dr. Sutherland for affording us this information from a tremendous data base. Few private hospitals have so many good records for such a long period.

An element that has disturbed me for a long time and that affects many of our breast patients will be introduced into the long-term survival situation. That is, the effect of aggressive systemic therapy (chemotherapy) on long-term survival.

(Slide) This graph from Baptist Memorial Hospital, Memphis, shows ten years' survivals from date of treatment of 800 patients out of about 1900 treated from 1965–1973. Note that 28% of those who had positive axillary nodes were alive and well ten years later (prechemotherapy years).

(Slide) This slide, from 1974–1983, very nearly duplicates the previous one. The graph is based on only 238 patients who are eligible for ten years evaluation, about 27% of axillary node positive patients are alive without demonstrable cancer ten years after treatment (chemotherapy years).

If aggressive systemic therapy or adjuvant therapy for breast cancer is beneficial, then the group of patients with positive axillary nodes should reflect that benefit. There have been two reports that aggressive systemic therapy did not increase five-year survival. Our data indicates no difference in ten-year survival between the two groups.

My question: Did you consider or evaluate systemic therapy in your patients' survival data?

DR. MARSHALL URIST (Birmingham, Alabama): I would like to congratulate Dr. Sutherland on a fine presentation of a well analyzed series. A long-term study such as this one gives us an opportunity to examine not only pathologic prognostic factors, but also the results of treatment. As we all know, treatment has changed remarkably over the long period of time covered in this study.

At the University of Alabama we have recently completed the ten-year analysis of a prospective randomized trial comparing modified and radical mastectomy. The results of this trial show that there has been a significant reduction in local recurrence when radical mastectomy is utilized for patients with T2 tumors and clinically palpable nodes and patients with T3 cancers.

It would be interesting to know whether any such benefit has been observed for patients treated with radical mastectomy *versus* modified radical mastectomy in the Tulane series.

DR. EDWARD T. KREMENTZ (New Orleans, Louisiana): I wish to compliment Drs. Sutherland and Mather on their detailed analysis of the Charity Hospital Tumor Registry data on breast cancer. The material will be important for future study and treatment of breast cancer. It also counteracts much of the "therapeutic nihilsm" regarding the surgical treatment of breast cancer that is being fostered by some of our medical colleagues.

In this centennial year, I wish to comment on the part that members of the Southern Surgical Association have played in the development of the Tumor Registry at Charity Hospital. The Registry was started in 1948 as a result of activities of a coordinating committee of the Louisiana Division of the American Cancer Society, and was composed of faculty members from The Louisiana State University (L.S.U.) and Tulane. The three major persons involved were Dr. Ambrose Storch of Tulane, Dr. James Rives of L.S.U., and Dr. Alton Ochsner of Tulane, who obtained funding from the Louisiana Division of the American Cancer Society to start a registry of cancer patients at Charity Hospital.

By 1952, the simple card file system had become unworkable. Dr. Walter Burdette of the L.S.U. faculty initiated action to establish a formal Tumor Registry Board and obtained support for this activity from the Cancer Society and other involved organizations. Drs. C. Hammond and C. Aubrey Schneider of the American Cancer Society National Office in New York City came to New Orleans to reorganize our data collection system and put the registry on a sound statistical basis.

The original board included Dr. Rawley Penick and Dr. Burdette, who served as Chairman; the Director of Charity Hospital, a representative from the Louisiana Health Department, and myself. All three surgeons were or became members of the Southern Surgical Association.

In 1955, Walter left to become Chairman of Surgery at Missouri, and I was elected Chairman of the Registry. The Board found outside sources to fund the majority of the Registry's activities until the middle 1970's. During this time, nine of the 40 board members have been S.S.A. members. In 1981, a bill was initiated in Louisiana to use cigarette tax money to support cancer control activities, and since then, those funds have supported the Charity Hospital Tumor Registry. This legislation was the result of activities started by Dr. Robert Beazley of L.S.U. and other persons active in cancer control activities, including my associate at Tulane, Dr. R. Davilene Carter.

Our Registry at Charity Hospital is remarkable in that it now contains over 67,000 cancer case entries, all of them computerized and available for statistical analysis by Charity staff members. Sixty-five per cent of the cases are black patients, and 35% of the cases are white. There are all sorts of interesting data for analysis in the computer banks. For instance, in my field of interest, there are over 100 cases of melanoma in black patients, which is the largest number reported from a single hospital in North America.

Faculty members at Tulane and L.S.U. have published approximately 400 publications utilizing data produced by the Tumor Registry. The 39-year data collection has been carried out by three Registrars: Mrs. Marian Wogon, Mrs. Brent Robertson and Mrs. Jane Rodriguez, who have been aided by a very dedicated group of helpers. The role of Louisiana members of the SSA has been and will continue to be an important part of cancer control studies at Charity Hospital and in the state of Louisiana.

DR. CARL M. SUTHERLAND (Closing discussion): I would like to thank all of the discussants for their interest, comments, and questions.

Numerous questions were presented by Drs. Copeland, Pigott, and Urist on treatment-related variables. In this study we did not analyze using treatment variables.

To answer Dr. Humphrey's question about one's being able to analyze for local recurrences related to type of therapy, in the future, I or any other Charity Hospital staff member will be able to perform this analysis. It will certainly be a good study, and will yield additional data on local recurrence factor.

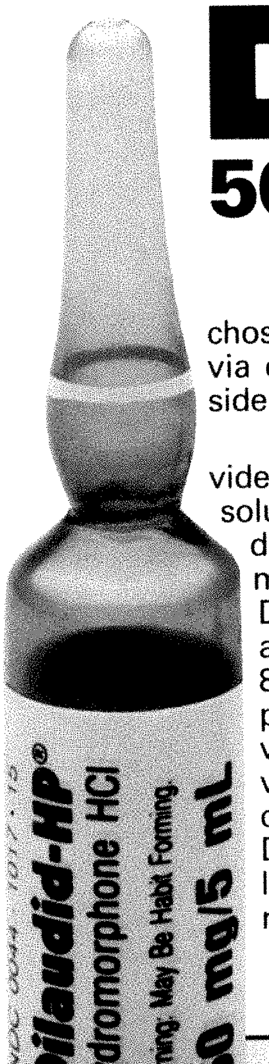
To reply to Dr. Humphrey's question regarding the similarity of survival between the group of patients being clinically node-negative with fixation and those clinically node-positive without fixation, an overall trend occurs; that is, as the important factors increase in number and severity, the stage increases while differences between the various groups decrease, and an overall poorer and more uniform survival occurs as the accumulation of those important factors increases. However, the relationship of those factors to each other, as well as what the biologic factors are, is unclear. In any of these prognostic factor studies that we perform, we can study only the clinical factors. The underlying biologic factors causing these clinical factors are unknown and require additional study.

That same comment applies, to some extent, to Dr. Beazley's question about findings of peau d'orange, which is a clinical manifestation of an underlying biologic process. Again, I would like to emphasize that peau d'orange is related to stage. If a prognostic factor study is conducted in any group of patients, and if a factor is related to the stage of disease being studied and that stage of disease is restricted, then the analysis may become confounded. While a study restricted to a stage is valid for that study, entirely different results are possible when additional stages are included.

When high concentration in a limited volume is critical...

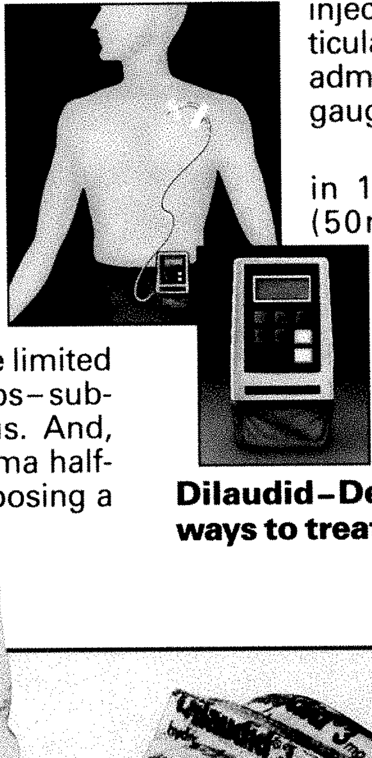
Dilaudid-HP® * CII

50 mg/5 mL.



For control of severe pain, you've chosen high dose parenteral narcotics via continuous infusion. Now, consider Dilaudid HP.

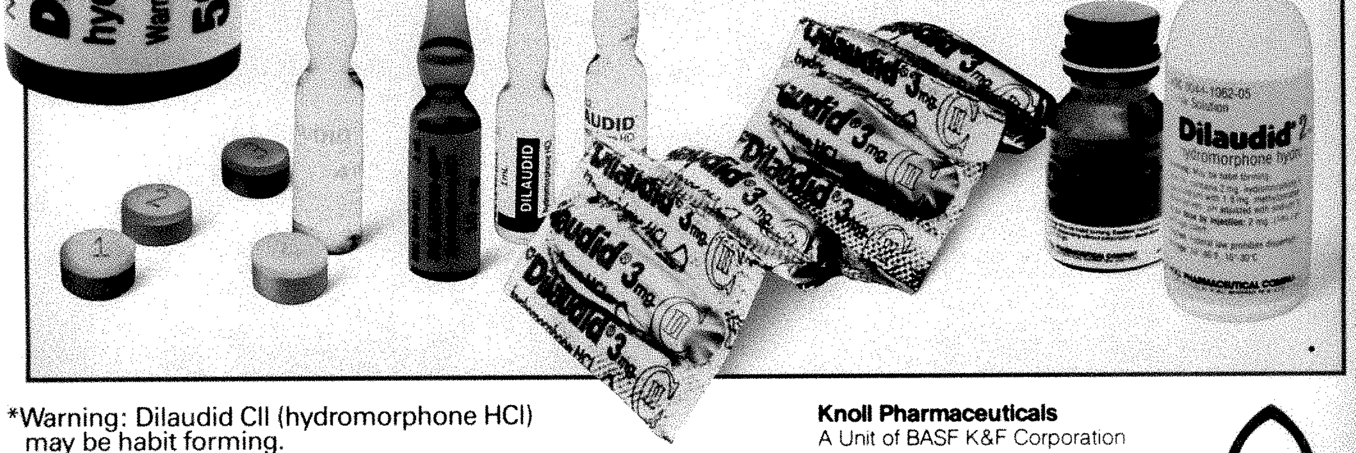
New Dilaudid HP® provides a highly concentrated solution (10mg/mL) of hydromorphone HCl. Each milligram of parenteral Dilaudid provides the analgesic equivalence of 8mg of parenteral morphine sulfate. This is vitally important given the limited volume of infusion pumps–subcutaneous or intravenous. And, Dilaudid has a short plasma half-life so essential when choosing a narcotic for infusion.



Subcutaneous injections of Dilaudid HP are well-tolerated, with minimal pain and/or burning at the injection site. And, it's particularly well accepted when administered with a short 27 gauge needle.

Dilaudid HP is available in 1mL (10mg) and 5mL (50mg) ampules–ideal potency alternatives to reduce the need for frequent changes of pump reservoirs, and reduce pharmacy time, nursing time and patient cost.

Dilaudid–Designed for the many ways to treat chronic severe pain.



*Warning: Dilaudid CII (hydromorphone HCl) may be habit forming.

Please see brief summary of prescribing information on adjacent page.

BASF Group

knoll®

Dilaudid-HP® Ⓒ
hydromorphone HCl

Warning: May be habit forming

INDICATIONS AND USAGE: For the relief of moderate to severe pain.

CONTRAINDICATIONS: Hypersensitivity to hydromorphone, intracranial lesion associated with increased intracranial pressure: depressed ventilatory function (chronic obstructive pulmonary disease, cor pulmonale, emphysema, kyphoscoliosis, status asthmaticus).

WARNINGS

Drug Abuse and Dependence: DILAUDID is a Schedule C-II narcotic. Psychic dependence, physical dependence and tolerance may develop upon repeated administration of narcotics, therefore, DILAUDID should be prescribed and administered with caution.

Respiratory Depression: DILAUDID produces dose-related respiratory depression by acting directly on brain stem respiratory centers. DILAUDID also affects centers that control respiratory rhythm, and may produce irregular and periodic breathing.

Head Injury and Increased Intracranial Pressure: The respiratory depressant effects of narcotics and their capacity to elevate cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions or a preexisting increase in intracranial pressure. Furthermore, narcotics produce effects which may obscure the clinical course of patients with head injuries.

Acute Abdominal Conditions: Narcotics may obscure the diagnosis or clinical course of patients with acute abdominal conditions.

PRECAUTIONS

Special Risk Patients: DILAUDID should be used with caution in elderly or debilitated patients and those with impaired renal or hepatic function, hypothyroidism, Addison's disease, prostatic hypertrophy or urethral stricture.

Cough Reflex: DILAUDID suppresses the cough reflex; caution should be excercised when it is used postoperatively and in patients with pulmonary disease.

Usage in Ambulatory Patients: Narcotics may impair the mental and or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery; patients should be cautioned accordingly.

Drug Interactions: Patients receiving other narcotic analgesics, general anesthetics, phenothiazines, tranquilizers, sedative-hypnotics, tricyclic antidepressants or other CNS depressants (including alcohol) concomitantly with DILAUDID may exhibit an additive CNS depression. When such combined therapy is contemplated, the dose of one or both agents should be reduced.

Parenteral Administration: The parenteral form of DILAUDID may be given intravenously, but the injection should be given very slowly. Rapid intravenous injection increases the possibility of side effects such as hypotension and respiratory depression.

Pregnancy:*Pregnancy Category C.* Teratogenicity shown in hamsters at 600 times the human dose. There are no adequate and well-controlled studies in pregnant women. DILAUDID should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Nonteratogenic Effects: Babies born to mothers who have been taking opioids regularly prior to delivery will be physically dependent. The intensity of the syndrome does not always correlate with the duration of maternal opioid use or dose.

Labor and Delivery: Administration of DILAUDID to the mother shortly before delivery may result in some degree of respiratory depression in the newborn, especially if higher doses are used.

Nursing Mothers: It is not known whether this drug is excreted in human milk, therefore, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children have not been established.

FD&C Yellow No. 5: DILAUDID 1 mg. 2 mg. and 4 mg. color-coded tablets contain (tartrazine) dye which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. It is frequently seen in patients who also have aspirin hypersensitivity.

ADVERSE REACTIONS

Central Nervous System: Sedation, drowsiness, mental clouding, lethargy, impairment of mental and physical performance, anxiety, fear, dysphoria, psychic dependence, mood changes.

Gastrointestinal System: Nausea and vomiting occur infrequently; they are more frequent in ambulatory than in recumbent patients.

Cardiovascular System: Circulatory depression, peripheral circulatory collapse and cardiac arrest have occured after rapid intravenous injection. Orthostatic hypotension and fainting may occur if a patient stands up suddenly after receiving an injection of DILAUDID.

Genitourinary System: Ureteral spasm, spasm of vesical sphincters and urinary retention have been reported.

Respiratory Depression: See WARNINGS.

Splenectomy in Hematologic Disorders

The Ever-changing Indications

MORTON C. WILHELM, M.D., F.A.C.S., ROBERT E. JONES, M.D., READ McGEHEE, B.S., JAMES S. MITCHENER, M.D.,
WILLIAM R. SANDUSKY, M.D., F.A.C.S., and CHARLES E. HESS, M.D., F.A.C.P.*

*From the Departments of Surgery and Internal Medicine, *Division of Hematology-Oncology, University of Virginia Medical Center, Charlottesville, Virginia*

A comparison between a series of splenectomies performed at the University of Virginia Medical Center for hematologic disorders between 1946 and 1962 (Series I) and 1963 and 1982 (Series II) is presented. Four hundred splenectomies (20 per year) were performed between 1963 and 1982 compared with 94 (5.5 per year) between 1946 and 1962. Also noted in Series II was a sharp decline in the number performed each year between 1974 and 1983. The major factor responsible for these observations was the evolution of the staging laparotomy for malignant lymphomas, particularly Hodgkin's disease, and the decline in the average annual incidence of staging laparotomies since 1974. Staging laparotomy currently is rarely done for non-Hodgkin's lymphomas. Also contributing to the changes noted was an increase in the total number but subsequent fall in the annual incidence of splenectomy for hereditary spherocytosis, idiopathic hypersplenism, and myeloproliferative disorders in Series II. The average number of splenectomies for idiopathic thrombocytopenic purpura increased from 1.1 per year in Series I to 3.6 per year in Series II; the annual incidence during the study period of Series II, however, remained constant. The total number of splenectomies for hairy cell leukemia and Felty's syndrome increased from zero in Series I to 12 and 17, respectively, in Series II, whereas the number of miscellaneous reasons dropped from 29 (1.7 per year) in Series I to 15 (0.75 per year) in Series II. The mortality rate in Series I was 6.3% compared with 4.0% in Series II. No deaths occurred in Series II after 1979. Indications for splenectomy in Series II were for diagnostic purposes in 3.2%, therapeutic in 56.5%, staging in 39.5%, and restaging in 0.8%. Accessory spleens were found in 49 (12.5%) in Series II.

THE INDICATIONS FOR splenectomy in hematologic disorders have changed considerably over the past two decades. These changes have occurred mainly as a result of the evolution of the staging laparotomy to evaluate patients with Hodgkin's disease[1,2] and, to a lesser extent, non-Hodgkin's lymphomas.[3-5] Also contributing to this change has been the decline in the number of patients who require splenectomy for diagnostic purposes and a change in the indications for splenectomy.[5] To assess the impact of these and other factors on the indications and frequency of splenectomy for hematologic disorders, a retrospective review of all splenectomies at the University of Virginia Hospital over a 20-year period from 1963 to 1982 (Series II) was done and compared with an older series reported from the same institution from 1949 to 1962 (Series I).[6]

Materials and Methods

All splenectomies performed at the University of Virginia Hospital between January 1, 1963 and December 31, 1982 were reviewed. The indication for splenectomy was categorized as either therapeutic, diagnostic, or as a part of a staging or restaging laparotomy for malignant lymphomas. Included were several well-defined hematologic diseases, Felty's syndrome, cases of hypersplenism with nonspecific histopathologic findings in the spleen (idiopathic hypersplenism or primary splenic hyperplasia), and a miscellaneous group of disorders such as storage diseases, sarcoidosis, primary splenic tumors and malformations, and histiocytosis X (idiopathic histiocytosis).

A histopathologic review of all staging splenectomies, most of which were done as a part of a previous study,[2] all diagnostic splenectomies, and all splenectomies performed for idiopathic hypersplenism was performed. The morbidity and mortality rates for each subgroup

---

TABLE 1. *Indications for Therapeutic Splenectomy in Hematologic Disorders**

- Anemia
- Thrombocytopenia
- Granulocytopenia
- Hypermetabolism
- High output cardiac decompensation
- Mechanical compression of the stomach with early satiety
- Recurrent painful splenic infarcts
- Bleeding esophageal or gastric varices (rare)

*Modified from Hess CE.[5]

and for the entire series were also evaluated. Any death or complication occurring within 30 days after splenectomy or during the hospitalization for the splenectomy, regardless of the length of stay, was considered an operative event.

Therapeutic Splenectomy

Indications for therapeutic splenectomy varied considerably depending on the nature of the underlying disorder and the size of the spleen. In Table 1, the various factors that contributed to a decision to perform a therapeutic splenectomy are listed.[5] In many cases, a combination of these factors was present. Patients with massive splenomegaly, regardless of cause, usually manifested most of the abnormal findings listed in Table 1. Such patients often are referred to as having the "big spleen syndrom".[5,7] In patients with myeloproliferative disorders, chronic lymphocytic leukemia, hairy cell leukemia, and idiopathic hypersplenism, splenectomy was recommended because of a varying degree of the "big spleen syndrome."

In the majority of therapeutic splenectomies, however, the nature of the underlying disorder was a major factor in the decision to recommend splenectomy.

Idiopathic Thrombocytopenic Purpura

During the first 10 years of this study, splenectomy usually was performed in patients who either did not respond to a 4-week course of oral prednisone (a rise in platelet count of less than 25,000/mm^3 above pretreatment levels), or repeated relapse after either a good response (rise in platelet count of greater than 50,000/mm^3) or an excellent response (rise in platelet count of 100,000/mm^3 or greater to a level of 150,000/mm^3 or greater).[8] In the last 10 years of the study, many patients also had failed to respond to other therapeutic modalities including androgens and one or more cytotoxic agents.

In the current study, response to splenectomy was evaluated at 2–4 weeks after splenectomy. An excellent or complete response was defined as a rise in the platelet count of 100,000/mm^3 or more above preoperative values, a good or partial response was a rise of 50,000–100,000/mm^3 above preoperative values, and a failure as a rise of less than 50,000/mm^3 above preoperative values.

Hereditary Spherocytosis

Traditionally, splenectomy has been recommended in all adults and older children (above the age of 3 years) with a diagnosis of hereditary spherocytosis because of the risk of development of gallstones, aplastic crisis, and the possible late development of hemachromatosis.[9] Aplastic crisis has proven to be an unusual event, particularly in mild cases, and the late development of hemachromatosis has been challenged.[10] As a result, during the latter part of this study, splenectomy has not been recommended in mild cases. Hematocrit values to evaluate response were recorded at 2–4 weeks after splenectomy.

Felty's Syndrome

Splenectomy was recommended for patients with neutropenia, usually severe, and recurrent or resistant infections.[11] In more recent years, failure to respond to a trial of gold therapy often preceded the recommendation for splenectomy.

Autoimmune Hemolytic Anemia

Splenectomy was recommended for patients who either did not respond to a 2–4-week course of oral prednisone, or who repeatedly relapsed after an initial good or excellent response to prednisone.[9] Hematocrit values to evaluate response were recorded at 2–4 weeks after splenectomy.

Thrombotic Thrombocytopenic Purpura

Before the established efficacy of plasmapheresis in thrombotic thrombocytopenic purpura,[12] which occurred during the period covered by this study, splenectomy was recommended as a part of the initial therapy of this disorder.[13] Splenectomy is now recommended only in patients who fail plasmapheresis or continue to relapse when plasmapheresis is discontinued.

Diagnostic Splenectomy

A diagnostic splenectomy was performed in one or more of the following clinical settings: (1) a splenic tumor or defect usually demonstrated by one or more imaging techniques or angiography, (2) fever of unknown origin with or without splenomegaly after an exhaustive investigation failed to reveal a definitive diagnosis, and (3) massive splenomegaly with varying elements of the "big spleen syndrome"; in most of these

cases a therapeutic indication also existed. In many cases of idiopathic hypersplenism, a diagnostic component was present.

Staging Laparotomy

Since 1969, the indications for a staging laparotomy for Hodgkin's disease at the University of Virginia Hospital have remained essentially unchanged.[2,14] All patients who were considered operable candidates with clinical stage I-IIA and B, I-IIEA and B, and many with clinical stage IIIA disease, were recommended for staging laparotomy.

The indications for staging laparotomy in non-Hodgkin's lymphomas changed dramatically during this study period. For approximately 7 years, from 1970 to 1977, patients with non-Hodgkin's lymphoma who were considered candidates for radiotherapy alone for curative intent were recommended to undergo a staging laparotomy.[14] Most of these patients had clinical stage I-IIA disease. Over the last 5 years of the study, a staging laparotomy usually was not recommended even in patients who were considered candidates for radiotherapy alone for curative intent.

Restaging Laparotomy

A restaging laparotomy to include a splenectomy, when appropriate, was recommended for patients with residual lymphadenopathy or splenic tumors or defects after the completion of definitive therapy, either radiotherapy, combination chemotherapy, or both, in patients with Hodgkin's disease and non-Hodgkin's lymphoma.[15]

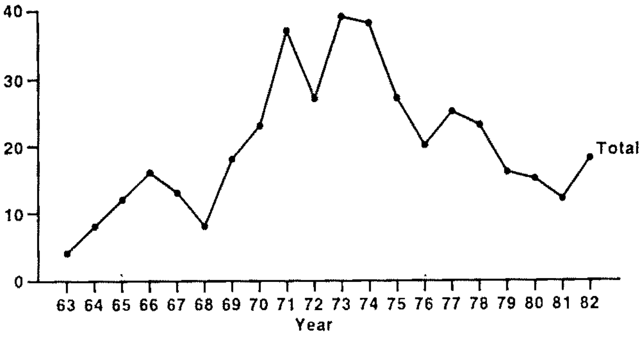

FIG. 1. Annual incidence of splenectomy for hematologic disorders: 1963–1982.

Results

In Table 2 are the number and relative frequency of the various hematologic disorders for the 20-year period, 1963–1982 (Series II), covered by this study along with a comparison with the previous report from this institution covering a 17-year period, 1946–1962 (Series I).[6] Patients with congestive splenomegaly secondary to intrinsic liver diseases were excluded from the current study. The actual number of splenectomies performed each year for all hematologic disorders is shown in Figure 1. A breakdown as to the major reason for performing the splenectomy is shown in Table 3. Accessory spleens were found in 49 (12.5%) of cases in Series II.

Morbidity and Mortality

The morbidity and mortality, overall and for each major diagnostic subgroup, are summarized in Table 4. In the three patients in whom a pulmonary embolus developed, only one had thrombocytosis (platelet count 819,000/mm^3) after a splenectomy for ITP in whom a pulmonary embolus occurred on the tenth postoperative day.

No operative deaths were observed in the 136 patients who underwent staging laparotomy for Hodgkin's disease (Table 4). The only death occurred in the one therapeutic splenectomy done in 1963, a 23-year-old man with massive splenomegaly.

Of the two deaths in the idiopathic thrombocytopenic purpura group, one, a 66-year-old man, died of gastroin-

† Miscellaneous group includes idiopathic histiocytosis, storage diseases, hamartomas, sarcoidosis, acute leukemia, nephrotic syndrome, myelodysplastic syndrome, and aplastic anemia.

‡ Complications occurred in same patient.

HD = Hodgkin's disease; NHL = non-Hodgkin's lymphoma; ITP = idiopathic thrombocytopenic purpura; HHA = hereditary hemolytic anemia; IH = idiopathic hypersplenism; MPD = myeloproliferative disorder; AIHA = autoimmune hemolytic anemia; HCL = hairy cell leukemia; FS = Felty's syndrome; CLL = chronic lymphocytic leukemia; TTP = thrombotic thrombocytopenic purpura; MISC = miscellaneous group

testinal hemorrhage and renal failure on postoperative day 1; the other, a 19-year-old female, died on the third postoperative day of respiratory failure.

Two of the four deaths in the myeloproliferative disorder group were from sepsis, one on postoperative day 24 and one on day 7. A third patient died of cardiopulmonary arrest on the day of the operation, and the fourth died on day 17 of a pulmonary embolus and pneumonia.

One of the two deaths in the Felty's syndrome group, a 60-year-old man, was due to cardiac arrest on postoperative day 3; the second, a 66-year-old woman, died on day 21 of undetermined cause.

All five deaths in the group with thrombotic thrombocytopenic purpura were due to progression of their disease.

One of the two deaths in the miscellaneous group was a 66-year-old man with acute leukemia and massive splenomegaly who died with disease progression on postoperative day 30; the other patient, a 69-year-old woman with malignant histiocytosis, died on postoperative day 12 of sepsis. No operative deaths occurred since 1979.

Hodgkin's Disease

All patients underwent splenectomy for staging except one patient who underwent splenectomy for Hodgkin's disease. The mean age was 28.4 years (range: 7–72 years), and the male:female ratio was 0.93:1. In 44 patients (32.1%), the spleen was positive for Hodgkin's disease. The mean weight of positive spleens was 403.3 g (range: 70–2090 g) compared with 207.5 g (range: 50–489 g) for negative spleens. Accessory spleens were found in 20 patients (14.6%). In Figure 2 the actual number of splenectomies performed each year for staging of Hodgkin's disease is compared with the actual number of splenectomies performed each year for all hematologic disorders.

Non-Hodgkin's Lymphomas

Of the 35 splenectomies in this group, 22 were for staging, three were for restaging, three were diagnostic, and six were therapeutic. A comparison of the actual number of splenectomies performed each year for staging laparotomy in non-Hodgkin's lymphomas and the actual number of splenectomies performed each year for all hematologic disorders is shown in Figure 3.

Idiopathic Thrombocytopenic Purpura

The actual number of splenectomies performed each year for idiopathic thrombocytopenic purpura is compared with the actual number of splenectomies performed each year for all hematologic disorders in Figure

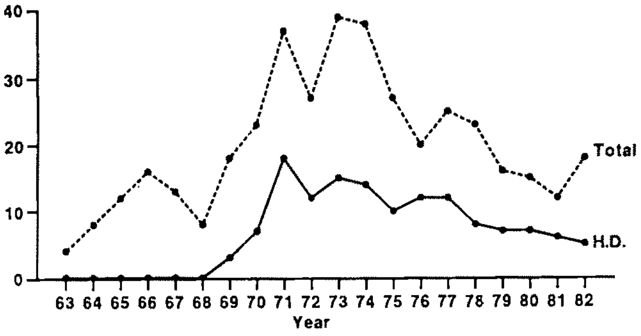

FIG. 2. Comparison between the annual incidence of splenectomy for staging of Hodgkin's disease (HD) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

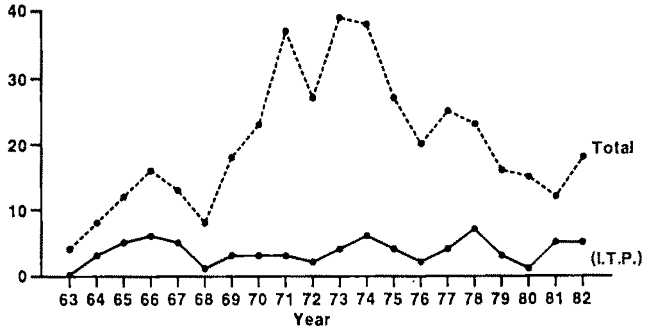

FIG. 4. Comparison between the annual incidence of splenectomy for idiopathic thrombocytopenic purpura (ITP) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

4. An excellent response was observed in 83%, a good or partial response was observed in 6%, and a poor response was observed in 11%. The mean platelet count was 46,890/mm^3 before operation and 409,980/mm^3 after operation. The mean splenic weight was 160 g (range: 22–530 g), the mean age was 35.7 years (range: 2–76 years), and the male:female ratio was 1:1.84. There were two deaths (2.7%). Accessory spleens were found in eight patients (11.2%).

Hereditary Hemolytic Anemia

Of the 45 splenectomies in this group, 39 were for hereditary spherocytosis, four for hemoglobinopathies, and two for enzymopathies. A comparison of the actual number of splenectomies performed each year for hereditary spherocytosis to the actual number of splenectomies performed each year for all hematologic disorders is shown in Figure 5. Only one splenectomy has been performed for hereditary spherocytosis since 1976. In the hereditary spherocytosis group, the mean age was 14 years (range: 8 months–48 years), the male:female ratio was 1:1.24, the mean splenic weight was 381 g (range: 30–1580 g), mean hematocrit increased to 38% from 29% before operation, mean reticulocyte count decreased from 13.1% to 2.1% after operation, and 12 (30.7%) accessory spleens were found.

Idiopathic Hypersplenism

Of the 14 cases, seven were for diagnostic and seven were for therapeutic reasons. A comparison of the actual number performed each year with that of all hematologic disorders is shown in Figure 6. The mean age was 45 years (range: 2–66 years), the male:female ratio was 3.67:1, and the mean splenic weight was 722 g (range: 200–2700 g). In the seven splenectomies performed for therapeutic reasons, a significant rise in either the hematocrit, white blood cell count, or platelets occurred in all patients at 2–4 weeks after splenectomy.

Myeloproliferative Disorders

In this group, 24 patients had myelofibrosis with myeloid metaplasia, and eight had chronic myelocytic leukemia. A comparison of the actual number each year with the actual number each year of all hematologic disorders is shown in Figure 7. In the myelofibrosis group the mean age was 59.2 years with a male:female ratio of 2.1:1. The mean hematocrit was 31% before

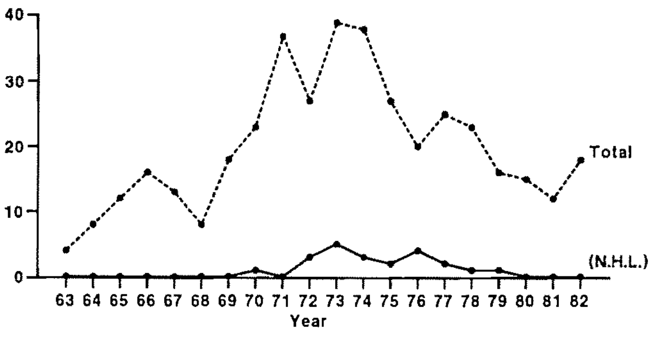

FIG. 3. Comparison between the annual incidence of splenectomy for staging of non-Hodgkin's lymphoma (NHL) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

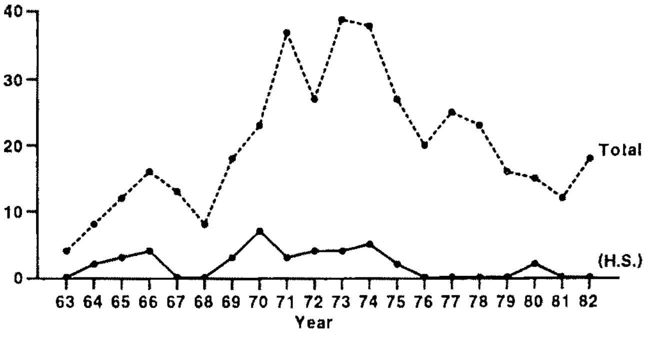

FIG. 5. Comparison between the annual incidence of splenectomy for hereditary spherocytosis (HS) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

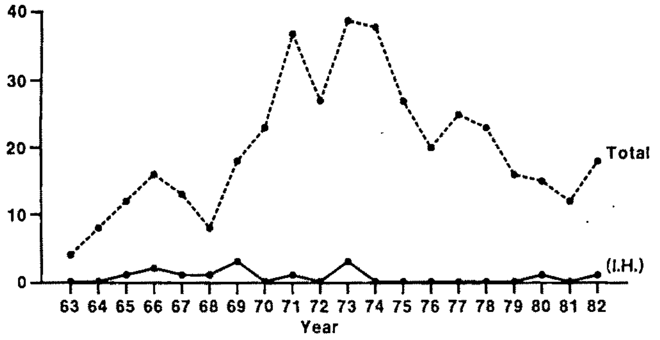

FIG. 6. Comparison of the annual incidence of splenectomy for idiopathic hypersplenism (IH) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

operation and 44% at 2–4 weeks after operation; the mean platelet count was 103,000/mm³ before operation and 212,670/mm³ at 2–4 weeks after operation. The mean splenic weight was 1999 g (range: 640–4400 g). Four (16%) accessory spleens were found. For the eight cases of chronic myelocytic leukemia, the mean splenic weight was 1900 g (range: 332–4300 g), the mean age was 36 years (range: 2–71 years), and the male:female ratio was 3:1. One accessory spleen (13%) was found.

Autoimmune Hemolytic Anemia

The mean age for the eight patients in this group was 54.5 years (range: 21–68 years) and the mean splenic weight was 389 g (range: 253–560 g). The mean preoperative hematocrit was 26% (range: 19–35%), compared with a mean postoperative hematocrit at 2–4 weeks of 44% (range: 30–53%). No accessory spleens were found.

Hairy Cell Leukemia

Eleven of the 12 splenectomies in this group were performed for therapeutic reasons. The mean age was 52 years (range: 39–64 years), the mean splenic weight was 1467.3 g (range: 786–2330 g), and one accessory spleen (8.3%) was found.

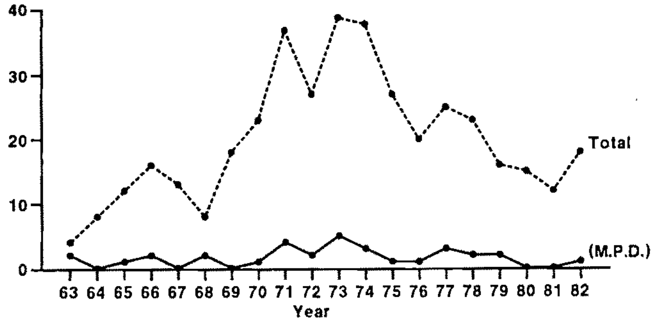

FIG. 7. Comparison of the annual incidence of splenectomy for myeloproliferative disorders (MPD) and the incidence of splenectomy for all hematologic disorders: 1963–1982.

Felty's Syndrome

The mean age of the 17 patients in this group was 58 years (range: 37–70 years), the male:female ratio was 1:43.1, and the mean splenic weight was 653 g. The mean white blood cell count was 2256/mm³ before operation and 7712/mm³ at 2–4 weeks after operation. Two accessory spleens (11.8%) were found.

Chronic Lymphocytic Leukemia

All seven cases were for therapeutic reasons. The mean splenic weight was 2946.6 g (range: 1420–4790 g). Only one has been done since 1978.

Thrombotic Thrombocytopenic Purpura

Splenectomy was performed as a part of the initial therapy in all of these patients, and five died in the postoperative period.

Miscellaneous

Splenectomy in all 15 patients in the group was performed for therapeutic and/or diagnostic reasons. Three were for splenic hamartomas, three for storage diseases (2 Gaucher's disease, 1 sea blue histiocyte syndrome), two for sarcoidosis, two for idiopathic histiocytosis (1 histiocytosis X, 1 malignant histiocytosis), two acute leukemias, one with nephrotic syndrome and intra-abdominal lymphadenopathy (findings were non-specific), one myelodysplastic syndrome, and one aplastic anemia (Fanconi's type).

Discussion

The average number of splenectomies performed each year for hematologic disorders during the 20-year period, 1963–1982 (Series II), covered by this retrospective study was 20 per year compared with only 5.5 per year over a 17-year period, 1949–1962 (Series I), in a previous report from this institution (Table 2).[6] When the actual number of splenectomies performed each year during this study was plotted, a marked increase occurred in 1969, peaking in 1971, 1973, and 1974 (Fig. 1). Since 1974, except for a slight increase in 1977 and 1982, there has been a steady decrease in the number of splenectomies performed each year (Fig 1). These changes have been the result of several important factors.

The impact of the staging laparotomy for malignant lymphomas, especially for Hodgkin's disease[1,2] was by far the most important factor. Beginning in 1969 (Fig. 2), the year the first staging laparotomy for Hodgkin's disease was performed at the University of Virginia Hospital,[2] the marked increase and subsequent decline in the number of laparotomies performed paralleled the rise and fall in the total number of splenectomies done (Fig. 2).

The decline in the number of staging laparotomies for Hodgkin's disease since 1974 is multifactorial, but may be due mainly to the changes in referral pattern observed over the past few years. Several private hematologists, oncologists, and radiotherapists have established practices in our referral area since 1975, and care for an increasing number of patients with malignant lymphomas.

Other factors have also contributed to the decline. Most patients with clinical stage IIIA disease, particularly those with $IIIA_2$ disease who would have been considered candidates for a staging laparotomy during the early 1970s, no longer are recommended to undergo a laparotomy.[14] Such patients are now treated with combination chemotherapy alone with or without supplemental radiotherapy as the initial curative therapy. A similar change occurred in our approach to patients with very large mediastinal masses (greater than one third of the diameter of the chest), especially if B symptoms are present.[14]

Although to a lesser degree, the emergence and essential disappearance of the staging laparotomy for non-Hodgkin's lymphomas during this study period has had an impact similar to that of the staging laparotomy for Hodgkin's disease on the annual incidence of splenectomies (Fig. 3). Only a rare staging laparotomy is currently recommended even in the few patients who are considered candidates for radiotherapy alone for curative intent.[14] No staging laparotomies have been performed since 1979 (Fig. 3).

The sharp increase in the average number of splenectomies performed each year for other hematologic disorders in Series II (Table 2), and the changes observed when the actual number performed for each disorder was plotted also were important factors.

The average number per year for idiopathic thrombocytopenic purpura increased from 1.1 in Series I to 3.5 in Series II (Table 2), for hereditary hemolytic anemia increased from 1.1 in Series I to 2.3 in Series II, for myeloproliferative disorders increased from 0.4 in Series I to 1.6 in Series II, for hairy cell leukemia increased from none in Series I to 0.6 in Series II, for Felty's syndrome increased from none in Series I to 0.8 in Series II, for chronic lymphocytic leukemia increased from 0.06 in Series I to 0.35 in Series II, and for thrombotic thrombocytopenic purpura increased from none in Series I to 0.3 in Series II (Table 2). Less splenectomies were performed for miscellaneous reasons in Series II, 0.75 per year *versus* 1.7 in Series I (Table 2). Patients with congestive splenomegaly secondary to hepatic cirrhosis were not included in Series II.

When the actual number of splenectomies performed annually for each disorder was plotted, only the idiopathic thrombocytopenic purpura group remained essentially the same throughout the study period (Fig. 4). In the hereditary spherocytosis group, a drop occurred after 1974 (Fig. 5), in the idiopathic hypersplenism group, a drop occurred after 1973 (Fig. 6), and in the myeloproliferative disorder group, a drop occurred after 1979.

The steady rate of splenectomies performed for idiopathic thrombocytopenic purpura is indicative of the fact that a significant number of such patients still require splenectomy for control of their disease.[8,16-18]

The change observed in the spherocytosis group probably was the result of the change in our policy regarding splenectomy in this disorder,[9] and possibly a change in referral pattern. Splenectomy is not currently recommended for mild cases.

In the case of idiopathic hypersplenism, improved technology, especially the availability of new imaging techniques and fine needle aspiration of intra-abdominal lymph nodes and masses, has improved tremendously our diagnostic capability in patients with fever of unknown origin with or without splenomegaly and in patients with splenomegaly in general.[5] The same reasons probably account for the very low percentage (3.2%) of diagnostic splenectomies in this study (Table 3). A diagnostic splenectomy probably should not be performed in relatively asymptomatic patients with splenomegaly, even with a varying degree of peripheral cytopenia, if a systematic and exhaustive evaluation fails to elucidate a cause.[5] A liver biopsy to rule out intrinsic liver disease should precede any decision to recommend a splenectomy in such patients. In the absence of intrinsic liver disease, splenectomy frequently reveals only nonspecific histopathologic changes. The only exception is when a splenic defect or tumor mass is noted on imaging.

The only apparent explanation for the decrease in the number of therapeutic splenectomies for myeloproliferative disorders is a change in referral pattern; there have been no advances in other treatment modalities.

The overall mortality rate of 4% and morbidity rate of 13.5% (Table 4) are comparable to several other large series of splenectomies for hematologic disorders.[6,19-23] The very high mortality rate of 83% (Table 4) in patients with thrombotic thrombocytopenic purpura (representing 31% of the deaths in this series) is similar to other reports where splenectomy is performed as a part of the initial therapy for this disorder.[12,13] With the marked improvement in survival observed with plasmapheresis,[12] splenectomy is now recommended only in patients who do not respond or who continue to relapse after stopping pheresis.

The zero mortality rate in staging laparotomies, both in Hodgkin's disease and non-Hodgkin's lymphoma, the overall low morbidity rate, and absence of a mortality in any case between 1979 and 1983 continue to support the acceptability of the risk of splenectomy in selected patients with hematologic disorders.

The results of this review when compared with an older study from the same institution establish that the indications for splenectomy in hematologic disorders continue to change. Although diagnostic splenectomy is currently an unusual indication for splenectomy, therapeutic splenectomy remains the treatment of choice for a variety of well-defined clinical and laboratory manifestations in several hematologic disorders. Splenectomy as a part of a staging laparotomy for Hodgkin's disease is still indicated in the great majority of patients who are considered candidates for radiotherapy alone for curative intent. Splenectomy as a part of a restaging procedure to evaluate residual tumor masses or defects is indicated in some patients with Hodgkin's disease and non-Hodgkin's lymphoma.

DISCUSSION

DR. HENRY LAWS (Birmingham, Alabama): I would like to compliment Dr. Wilhelm and his colleagues on their excellent results in these diverse and often very complicated problems. Dr. Wilhelm asked us to discuss the paper because we managed 130 of these patients with hematologic disorders, not Hodgkin's staging, over a 12-year period with seven deaths.[1] Four of these patients died with overwhelming sepsis in the early postoperative period, usually with a very low, absolute granulocyte count. I would caution everyone to be concerned about operating on individuals of this nature with a granulocyte count below 100 or 200, even though the total white cell count may be several thousands.

Recently, we had occasion to do a splenectomy on an AIDS patient with cryptococcal meningitis, and very severe leukopenia and thrombocytopenia in the course of his disease. The severe leukopenia would not allow therapy with Retrovir. (Slide) This has also been observed by other individuals. Splenectomy afforded a dramatic increase in both the white count and the platelet count. On the other hand, when the AZT therapy was reinstituted, the white count promptly became too low to be tolerable again. I doubt that splenectomy was of any real benefit to this patient.

I would like to ask Dr. Wilhelm and Dr. Jones several questions. Of the patients who died, did severe granulocytopenia play a part? Are there any patients with early Hodgkin's Disease, for instance, Stage I or II on the right side, upper body, that you might not stage? What postoperative management or prophylaxis do you recommend for patients after splenectomy to avoid sepsis? Have you had any experience in the treatment of AIDS patients, and do you anticipate splenectomy to play any part in these individuals?

DR. NORMAN HALPERN (Birmingham, Alabama): Studies such as this one remind us that concepts of management of certain disorders can change substantially over time.

As Dr. Wilhelm indicated, this can be due not only to variations in referral patterns and development of presumably superior nonsurgical diagnostic and therapeutic options, but also to the eventual recognition that surgical management may, indeed, be highly effective in certain clinical settings.

We should also remember that there may be a good bit of variation in practice patterns between institutions.

(Slide) This is a slightly different time period at UAB than what Dr. Laws referred to, and reviews a 12-year experience up to 1985.

The most profound change in our clinical practice from the earlier to later years of this study was a dramatic decrease in the number of splenectomies for trauma. Operations for hematological disorders generally increased. Those for Hodgkin's staging showed a slight decline.

(Slide) Over the past six years I have had the privilege of being involved in nearly all of the splenectomies for hematologic disease at UAB, and I thought it would be of interest to compare this most recent experience with Dr. Wilhelm's later series. Using the data available from the program abstract, it would appear that there certainly are some differences.

There is a slight difference in the duration of the time frame, but I think we can make some contrasts with the numbers.

With Hodgkin's staging, however, our experiences are similar, and both show a somewhat declining yearly incidence. In our case, I suspect it is a matter of the patients' being managed elsewhere since our hematologists generally favor a policy of operative staging.

In a similar way, they have not been impressed with the results of gamma globulin or other recently promoted drugs for immune thrombocytopenia, so we are still seeing about eight or nine of those yearly.

Dr. Wilhelm, you show a large volume of patients with hereditary spherocytosis. In our system, children are cared for in a separate hospital. Were many of your spherocytosis patients in the pediatric group? You mentioned that operation was becoming less frequent for that indication, but when you do find the indication, what age guidelines would you suggest for splenectomy?

Another interesting difference was in the management of non-Hodgkin's lymphoma. All of our operations were for correction of hypersplenism or for diagnosis of splenomegaly, whereas at your institution, over half of yours used to be for staging. I had a question on the role of operative staging for non-Hodgkin's lymphomas, but you clarified it in your discussion.

In general, we have been quite satisfied with the results of splenectomy for selected patients with the various leukemias or myelofibrosis, realizing, of course, that operation is just a component of their overall therapy and that certainly more risk is involved with operation. Nevertheless, removal of a symptomatic, massively enlarged or hyperfunctioning spleen can contribute greatly to an improved quality of survival for these people.

I envy your experience with Felty's Syndrome. Your referral patterns are remarkably different from ours in that category.

Finally, in the miscellaneous group I have included our eight patients with thrombotic thrombocytopenia purpura, an interesting disorder that seems to be (at least in our institution) a bit more frequent recently. As your comment indicated, I think plasmapheresis has made a difference. Of those eight patients with TTP having splenectomy, all eight survived. Nevertheless, we still have a bit of difficulty defining the criteria that would indicate plasmapheresis has filled. Perhaps you could give us your thoughts on that.

Dr. Lazar J. Greenfield (Ann Arbor, Michigan): I would like to congratulate Dr. Wilhelm and his associates for their results and for his excellent presentation.

This is an area that has been of considerable interest to Dr. William Coon of our faculty, who is an acknowledged expert. Since I am not an expert, I would like simply to ask two questions.

First, was there any difficulty in any patient (with ectopic splenic tissue particularly in the ITP patients) who required reoperation?

Second, in some series, the incidence of conversion to AIDS positive has been distressingly high and increasing over a period of time to about the level of 25%. My concern is whether or not this has been seen in your population and whether this will affect the course of treatment of these patients.

Dr. Robert E. Jones (Closing discussion): Dr. Laws asked several pertinent questions, specifically, what our indications are for staging laparotomy in Hodgkin's Disease. In clinical Stage I and II disease (both A and B), we do perform staging laparotomies. It is only in the Stage III-B patients that we do not operate, and in some patients with clinical Stage III-A disease in which there is massive lymphadenopathy. Also if a person has massive thoracic lymphadenopathy in any stage with the tumor burden greater than one-third of the diameter of the chest, we do not perform a staging laparotomy in these patients.

The question of neutropenia playing a part in our mortality was pertinent. Approximately 30% of the operative deaths were due to sepsis postoperatively. This was primarily in the TTP group, which accounted for 30% of our total mortality.

The postoperative prophylaxis recommendations are that we do not give penicillin to everyone, only to the children who have splenectomy.

Currently we have not operated on the AIDS patients. We do expect that in the near future we probably will. This may be due to the big spleen syndrome.

Dr. Halpern asked a question about hereditary spherocytosis. Our average age was 14 years and our age range was 18 months to 48 years. We do recommend that a child greater than 3 years old have a splenectomy only for severe refractory hemolytic anemia, not in the mild to moderate hemolytic group; and in TTP, we do not have enough experience for treatment recommendations for splenectomy at present.

Dr. Greenfield asked about any difficulty with accessory spleens. We had a total incidence of approximately 12.3% accessory spleens with 30% occurring in the ITP group. We have no documented cases of relapse due to accessory splenic tissue.

In the October 1987 issue Annals of Surgery, from Duke University there is a recent report in which they used Indium labelled platelets and intraoperative hand-held isotope probes to localize accessory splenic tissue with excellent results.

As stated previously, Dr. Greenfield, we have currently not operated on the AIDS patients, but possibly in the near future we will, due to our referral pattern.

The Surgical Management of Esophageal Stricture in Children

A Century of Progress

H. BIEMANN OTHERSEN, JR, M.D., EDWARD F. PARKER, M.D., and C. D. SMITH, M.D.

Early in this century all procedures performed on the esophagus were accomplished through its lumen. Ingestion of caustics was common and resulted in dense strictures for which complicated and ingenious methods of dilation were advised. Because obstructions usually recurred, by-pass operations were devised with conduits of skin or segments of the gastrointestinal tract. Now, in contrast, when burns occur, intensive steroid therapy usually prevents all but localized areas of stricture. These areas, if short, can be treated with hydrostatic balloon dilation under fluoroscopic control. If longer or resistant to dilation, these strictures can be managed by incision and insertion of a colic patch with excellent long-term results. To a previous series of children who have had esophageal patch with a vascularized segment of colon, now added is an experience with a free segment of small intestine with vascular anastomosis to an artery and vein in the neck and another case of a free patch of pericardium to the esophageal stricture.

From the Divisions of Pediatric Surgery and Cardiothoracic Surgery, Medical University of South Carolina, Charleston, South Carolina

IN THE PAST 100 years, advances in medicine usually have occurred as a consequence of refinements in technique rather than as the result of new ideas and concepts. On the occasion of the 100th anniversary of the Southern Surgical Association, we felt that progress made in the management of esophageal strictures in children should be reviewed in order to define and refine current therapeutic regimens. Since an extensive review of the medical literature in English and in German disclosed no reports of experience with the colic patch in children, with the exception of the original description by Hecker and Hollmann,[1] it appears that our series of patients is unique and should be updated and assessed in light of historical review.

Within the past century, rapid progress has been made in the prevention and nonoperative therapy of esophageal strictures in children. In contrast, appendicitis, which was described by Reginald Fitz almost 100 years ago,[2] has experienced no advance in prevention, diagnosis, or therapy. Despite the most advanced computerized radiographic, magnetic, and nuclear imaging studies, the diagnosis of appendicitis is still based on clinical history and physical examination. Furthermore, the surgical therapy of appendicitis basically has remained unchanged for the past 100 years. This is not so for the esophagus!

This article presents the major milestones in the development of surgical therapy of esophageal strictures in children. Included are preventive measures as well as nonoperative therapy. The indications for and techniques of colic patch esophagoplasty have been reviewed and our series updated.[3]

The concept of incision of an esophageal stricture and insertion of a patch was orginally reported for the cervical and also the terminal esophagus. Not until Hecker and Hollmann's work was the application of this concept possible to the thoracic esophagus. We have extended their work and demonstrated the effectiveness of this technique in a series of children.

History

"What's Past is Prologue"
William Shakespeare
The Tempest (II.i.253)

Early medical writings concerned with the gullet, or esophagus, described various ingenious techniques and instruments for the extraction of foreign bodies. Their primary interest was relief of esophageal obstruction that could be caused by carcinoma or benign scars. Most strictures then were approached by internal esophagotomies and repeated dilations. In his book, *Thoracic Surgery before the 20th Century,* Hochberg describes an operation by Llobet that was performed in 1900.[4] Llobet

proached the esophagus extrapleurally through the osterior mediastinum.[5] He then performed longitu-inal incisions through the strictures of the lower esoph-gus. The wounds in the esophagus were left open after a oft rubber tube had been passed into the stomach ansnasally. Not surprisingly, the patient died on the th postoperative day.

Surgeons in the late 19th century operated on the ervical esophagus and avoided the pleural cavity before he development of positive pressure anesthesia. In 894, Bircher described an operation to circumvent an bstructed esophagus by the formation of a tube fabri-ated from the skin of the anterior surface of the thorax.[6] lthough the procedures were well planned, both of his atients died before the final stages could be completed. n 1920, Saint published a thorough treatise on esopha-eal repairs summarizing the knowledge at that time.[7] In complete and detailed review published in 1934 and ntitled, "Anterothoracic Oesophagoplasty for Imper-meable Stricture of the Oesophagus," Ochsner and Owens summarized the procedures that had been used p to that time.[8] They collected 240 cases from the world literature and added one of their own. There is no ecorded case of a completed esophagoplasty having een performed in the United States before this report. igure 1 shows a diagram from their paper that illus-rates the various techniques of esophagoplasty. Proce-dures used on both children and adults were: dermato-sophagoplasty (skin tube from the proximal esophagus o the stomach); jejunoesophagoplasty (jejunum from sophagus to stomach); jejunodermatoesophagoplasty jejunum from stomach to skin of chest wall and skin ube to neck); coloesophagoplasty (colon from stomach o neck); salpingogastroesophagoplasty (gastric tube to roximal esophagus); gastroesophagoplasty (entire tomach to the cervical esophagus). From their review nd personal experience derived from one case, the au-hors believed that anterothoracic esophagoplasty hould be used only in cases of absolutely impermeable enign stricture. Although they believed that the results with coloesophagoplasty were equally as good as those with jejunodermatoesophagoplasty, they preferred the atter technique. (Figs. 2–4)

An esophageal patch technique, which consists of in-cision of the lower esophageal stricture and coverage of the resulting defect with the serosal surface of the fundus of the stomach, was described by Thal and co-workers in 1965.[9] Thomas et al. added a skin graft to the serosal surface of the fundus before its application to the esoph-ageal defect and also advised fundoplication.[10] This technique has not received universal favor among sur-geons. In 1979, Hugh and his associates described the use of a vascularized antral patch with the pedicle based on the left gastroepiploic vessels.[11] The mucosa of the antrum was applied to the lumen of the esophagus and a concomitant fundoplication was performed. This technique was used only for esophageal strictures.

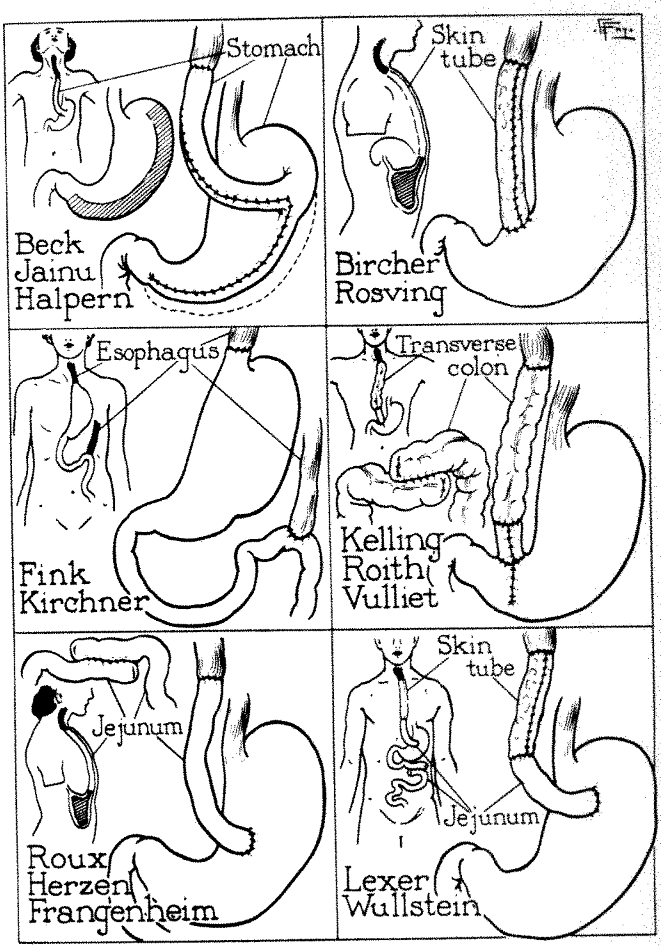

FIG. 1. Diagrams of the early extrathoracic procedures designed to bypass esophageal obstruction (from Oschner and Owens[8]).

No technique of vascularized patches inserted into the thoracic esophagus could be found before the publica-tion by Hecker and Hollmann in 1975.[1] They per-

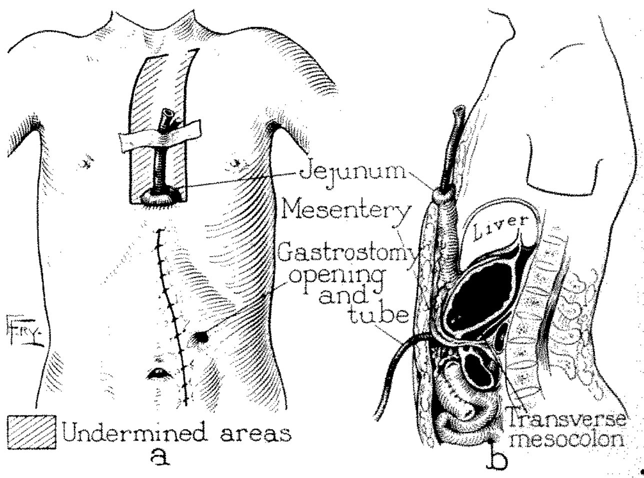

FIG. 2. First stage of bypass operation using a jejunal tube to the stomach and then attached to a skin tube to the proximal esophagus (from Oschner and Owens[8]).

formed initial experiments in dogs and reported two patients who were treated with this technique. There has been no subsequent publication of follow-up of those patients or the addition of any new ones. Dr. Antonio Gentil Martins of Lisbon indicated that he has presented this concept at a meeting but the report was not published. In 1985, we reported a 10-year experience with the use of the vascularized colic patch in the management of esophageal strictures in children.[3] Before that time, we initially had used gastric tubes but subsequently preferred the left colon brought up in an antiperistaltic manner and placed in the posterior mediastinum (Figs. 5A–C). Long-term follow-up of children with esophageal replacement revealed good initial function but eventual redundancy and stagnation in the interposed colon often associated with marked growth retardation.[12] We have been satisfied with the long-term results of the colic patch.

Prevention

Most esophageal burns are caused by the ingestion of caustic substances, lye in particular. Extensive educational programs have been launched in an effort to convince families not to use these corrosive substances and, if they must, not to store them in containers that ordinarily hold nondangerous substances. In the event of a serious esophageal burn, experimental evidence has shown that transmural burns are necessary for strictures. Prompt treatment with high doses of steroids and antibiotics or with intraluminal stents has prevented the development of extensive scarring and strictures throughout the entire esophagus.[13] Strictures may occur despite intensive steroid therapy, but they often tend to be more localized and amenable to treatment once the steroid therapy has been initiated. In the repair of esophageal atresia, the use of absorbable sutures of polyglycolic acid and the performance of the anastomosis in a single full-thickness layer have reduced the incidence of postoperative anastomotic stricture. Foreign bodies are now easily extracted with rigid or flexible endoscopes, and smooth objects such as coins can be retrieved without anesthesia by use of a Foley catheter under fluoroscopic control. Disc batteries, lodged in the esophagus, should be removed by esophagostomy before they produce necrosis and eventual stricture by leaking caustic chemicals and by galvanic action.[14]

Nonoperative Therapy

After the administration of high-dosage steriods or the insertion of an intraluminal stent has allowed healing of the acute injury, transmural necrosis may lead to strictures that are relatively localized. Anastomotic strictures are generally limited in their extent and respond well to balloon esophagoplasty early in their development before dense scarring occurs. Balloon esophagoplasty is accomplished through the use of angioplasty balloons, which can be located precisely in the stricture and dilated under fluoroscopic control. The inflation is guided manometric monitoring to confirm that the balloon s reached its proper diameter. This type of dilation ould prove much more effective than either antegrade retrograde bouginage due to the fact that the balloons ıply a radially directed force that stretches the stricture thout the shearing component, which may produce ucosal avulsion.

Surgical Therapy

Many surgical techniques developed for esophageal placement are still in use and Table 1 lists the advanges and disadvantages of the various esophageal reacements.

Colic Patch

Since this procedure was described and reported in)75, it has been used by the Pediatric Surgical Service the Medical University Hospital for the past 12 years. he technique is the same as described by Drs. Hecker ıd Hollmann with a few modifications.[1] We have used ɔth the extrapleural and transpleural approaches and

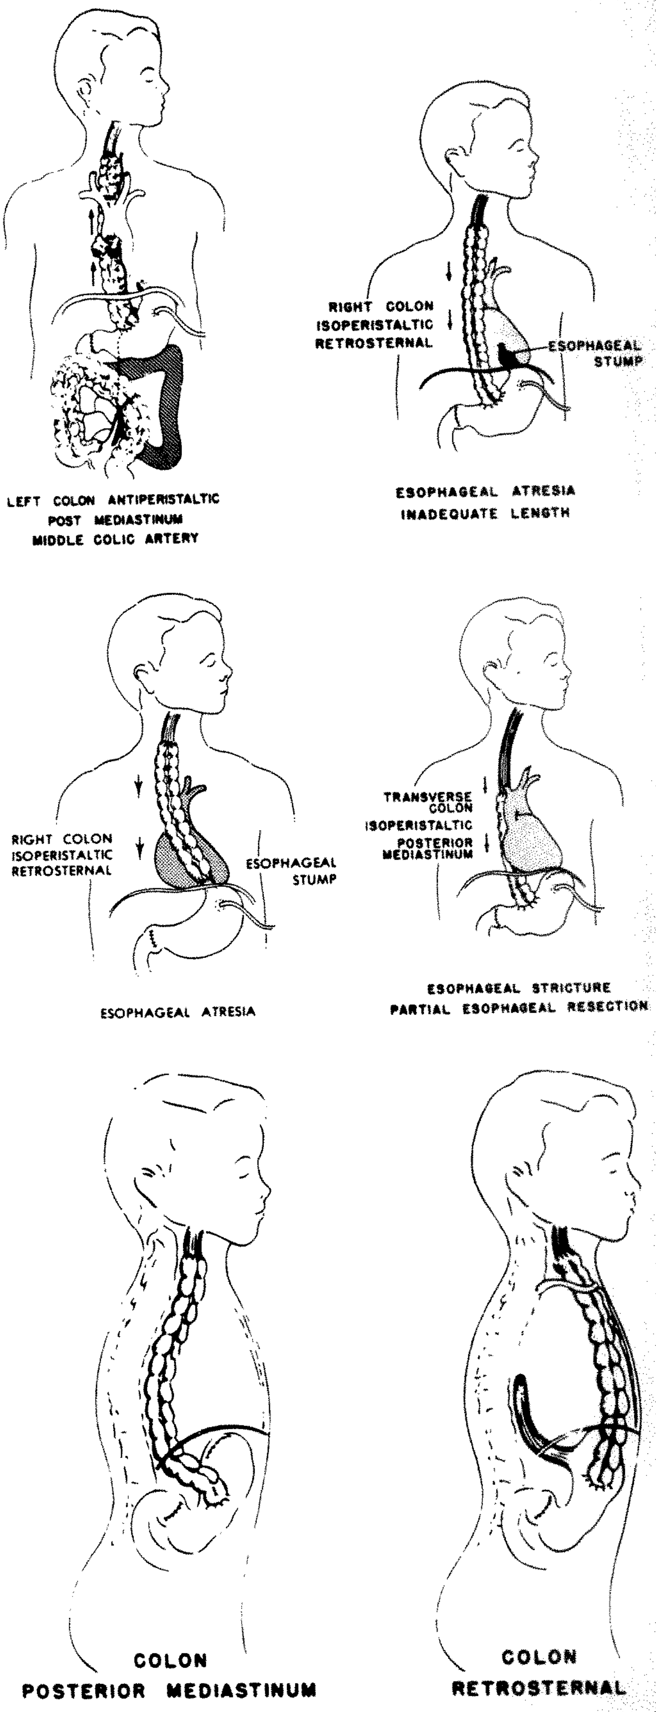

FIGS. 5A–C. Diagrams of various varieties of colic interposition. All of these, whether iso- or antiperistaltic and whether in the post mediastinum or substernally, function as conduits and empty by gravity.

TABLE 1. *Intrathoracic Esophageal Substitutes*

Technique	Advantages	Disadvantages
Small intestines	Large amount of intestine available	Blood supply lacks a marginal artery; difficult to obtain a straight conduit with good blood supply
Gastric tube	Stapling devices have simplified construction of the tube	Long suture line; may not be able to reach high in the neck; difficult to place in the posterior mediastinum
Colon	Acts as a conduit when placed either anti- or isoperistaltically; good blood supply with marginal artery and can reach high in the neck; can be placed in the posterior mediastinum in the esophageal bed	Long-term growth retardation; late redundancy and stasis; late strictures at the cologastric anastomosis
Entire stomach	Readily available and easy to mobilize	Blood supply may not allow it to reach high in the neck; large bulk may cause space problems when brought up intrathoracically
Colic patch	Can be tailored to the individual esophageal defect; good blood supply to reach high in the neck; does not require esophageal resection; esophageal continuity intact	Long suture line; cannot be used when entire esophagus is densely scarred; the scarred esophagus is left in place
Free patch of intestines	Only short portion of gut used—no useful intestine discarded; can be tailored to the individual area	Requires microsurgical anastomosis with threat of thrombosis and gangrene
Free or pedicled patch of pericardium	Readily available material and does not require vascular pedicle	Contracts and stricture may recur

believe that each is adequate. The segment of colon is based on the middle colic or the left colic artery. Careful measurements determine the length needed. The esophageal stricture is incised longitudinally until normal esophagus is reached at each end of the stenosis. A template of the patch size required is then made. The colic segment is opened on its antimesenteric border. The patch is fashioned while still in the abdomen. If the segment of colon is first brought into the chest and then trimmed, its location deep in the thoracic cavity makes control of hemorrhage more difficult. The colic segment is more accessible in the abdomen. When the patch has been fashioned, it is passed behind the stomach and through the esophageal hiatus into the chest. The patch should fit without redundancy and is sewed into place with polyglycolic acid sutures—either continuous or interrupted (Fig. 6). A 10-year report of results was published in 1985 with excellent long-term results in six patients and good results in three patients.[3] There were no major complications, but in three patients there was a tendency of the patch to bulge, producing a pseudodiverticulum. However, the functional results were good. When the patch was perfectly tailored to the defect, no bulging or redundancy was found. Endoscopic evaluation after patching showed good epithelial covering of the area of previous stricture with improved pliability of the esophageal wall. The patch is easily identified by the mucus adherent to it and by a slightly darker color of the mucosa.

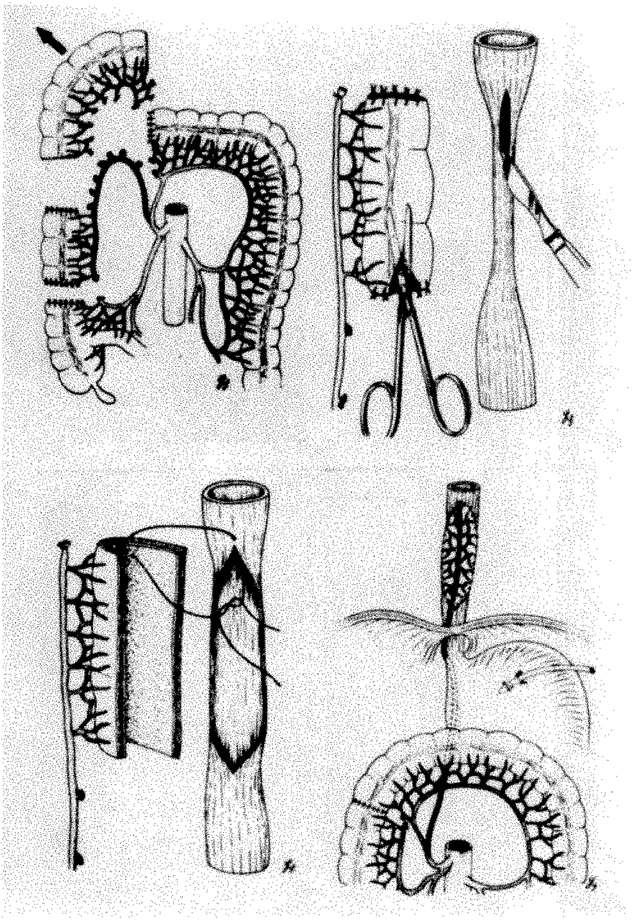

FIG. 6. Four steps in construction and application of a colic patch (from Hecker and Hollmann[1]).

Subsequent to our report,[3] we have used a free patch of small intestine anastomosed by microsurgical techniques to vessels in the neck. This patch was interposed into the cervical esophagus after a dense stricture resulted from caustic ingestion. A previous gastric tube interposition had also been used and a cervical leak had occurred, which added to the scarring. The free patch worked well with the exception of the development of an esophagocutaneous fistula at its lower margin where it was sutured into the esophageal defect. At that point on the patch, a single layer of chromic catgut was used; a second layer of polyglycolic sutures was not placed for fear of compression of the blood supply to the patch. In retrospect, a second layer of sutures should have been placed carefully or the single layer should have been polyglycolic acid sutures. In an additional case, a young boy had ingested lye and initial esophagoscopy showed an extensive burn. High-dose steriods (4–6 mg/kg/day of prednisone) were given and, eventually, a localized stricture (2 cm) remained as the only residual problem. The stricture was located in the distal esophagus but the remainder of the esophagus healed well without stenosis. Since the stricture was so short, it was believed that a free patch might allow the stenosis to be incised without the necessity of constructing a pedicled flap. The stenotic segment was therefore incised and the esophageal defect closed with a free patch of pericardium. Initial results were good and the patient was able to swallow without difficulty, but gradually, over 6–12 months, the stricture in that area recurred as the patch contracted. He has had balloon esophagoplasty but the stricture has recurred three times. If the stricture again returns, a pedicled colic patch will probably be required.

The advantages and disadvantages of the colic patch are listed in Table 2.

TABLE 2. *Colic Patch Esophagoplasty*

Advantages	
	Retains continuity of esophagus
	Less injury to vagus nerves
	Permits re-epithelialization and scar regression in surrounding esophagus
	Amenable to anastomosis of vascular supply to local vessels
Disadvantages	
	May form pseudodiverticulum if redundant
	Long intrathoracic suture line
	Difficult to carry anastomosis into the neck

Discussion

The colic patch currently offers advantages that outweigh any disadvantages. It is easily constructed and, with a good marginal artery, can be carried high into the chest. The only problem has been that a considerable amount of colon must be discarded to obtain adequate length to the pedicle, but the same amount of bowel would be used for a tubular colic interposition.

The current alternative operations are replacement or bypass with stomach, small intestine, or colon. The entire stomach, when brought up to the proximal esophagus, refluxes and occupies a large space in a small chest. The gastric tube also allows reflux of acid secretions and may not easily reach high enough. Small intestine lacks a marginal artery and must be redundant. Swallowing is a slow process when food must traverse an interposed piece of small intestine.

If the scarred colon is bypassed, it may accumulate secretions and eventually perforate or carcinoma may develop in the retained scar. This concern also may be applied to the colon that remains after a colic patch. There have been reports of carcinoma developing years after a chemical burn but the average time from injury to carcinoma is 30–40 years with a frequency of 1.2–2.6%.[15–17] Carcinoma has also been reported in anterothoracic dermatoesophagoplasties. In our patients who have had interposition of a colic patch, the scar in the esophagus has become much more pliable as the tension is relieved after insertion of the patch. Portions of the esophagus, which prior to the patch contain scar epithelium and granulation tissue, eventually become covered with esophageal mucosa. The possibility of carcinoma developing in some of our patients exists, but the risk is minimal.

Summary

In reviewing the progress of treatment of esophageal strictures in children over the past 100 years, there has been considerable improvement in our therapeutic regimens. The surgical treatment of strictures has been greatly facilitated by the use of the colic patch in which the interposed segment can be tailored to match the gaping defect after a longitudinal esophagotomy through the stricture. The esophagus is not resected from its bed and its nerve supply is not interrupted. There is admittedly no substitute for the damaged and scarred esophagus, but of the available conduits, the colic patch has been most satisfactory in our hands. We believe it will become the preferred method of treatment of esophageal strictures.

Acknowledgments

The authors express their deep appreciation to Megan Othersen for her dedicated editorial assistance and to Barbara Tamsberg for her expert typing of the manuscript.

DISCUSSION

DR. J. ALEX HALLER (Baltimore, Maryland): It is a pleasure to hear this excellent presentation and to have had the opportunity of reviewing Dr. Othersen's manuscript. While he has, in his manuscript, focused on the need for methods of replacing the injured esophagus, he also very properly emphasizes the importance of preventing the stricture, and I think that may have been an even more important development over the last 100 years than these various operative procedures for the correction of the established stricture.

We have not had the opportunity of using the colon patch in this country that Dr. Othersen himself has described, following the report from Germany; but I would like to ask him about any long-term complications in these children, because my personal worry is that abnormal mucosa in this position might actually represent a site for the development of carcinoma over the 50, 60, or 70 years that lie ahead.

I would like to ask him whether this has been reported at all from the European experience, or whether those children have lived long enough to have developed any such complications.

The other technical question is: How long a segment can the colon patch replace? In the shorter strictures, we have felt it is better to resect and carry out a primary anastomosis, and not to bring up a segment of jejunum or colon. In the last 10 years, using the primary steroid treatment which he has outlined, we have had only one long-term stricture following caustic injuries in children. That was a short stricture, and it was possible to correct it with resection and a primary anastomosis.

I would like to ask one other question, and that has to do with the experience with some of the liquid sodium hydroxide agents that are currently becoming more and more available in the homes. Until recently, I did not think they were a problem in children and young teenagers; but recently I heard the remarkable experience in Winston-Salem of a group of teenagers who found liquid sodium hydroxide in the refrigerator, thought it was wine, rapidly drank it, and all of them had severe esophageal burns, and some also perforated their stomachs.

Dr. Othersen, have you dealt with this sort of problem before, and is this going to be an increasing problem now and for the next 100 years?

DR. MAURICE J. JURKIEWICZ (Atlanta, Georgia): I want to compliment Dr. Othersen on two things, not only his presentation, but also that he is now from the Division of Plastic Surgery at the Medical University of South Carolina, so the program states. I don't know how that happened.

I should like to make a comment on your own experience and ask two questions. The questions that I have are similar to that of Alex Haller. What is the long-term follow-up on such patients? Is there a possibility of cancer arising in that damaged yet recovered segment?

(Slide) These data were put together by John Coleman in our institution. They relate to the experience we have had with jejunum autografts transplanted into the neck and other areas. These data are limited to transplants of jejunum done in the neck. We have had experience with patch grafts in the 13 patients, six of which were in patients with cancer and seven with benign conditions. We use either a cylindrical tube to replace the entire segment filleted as a patch.

(Slide) The stricture was limited to the cervical esophagus. As you can see, she had a ribbon of apparently normal mucosa in the posterior wall of the esophagus. A patch graft was used (Slide), revascularized in the neck.

We reported her and other patients to this organization in 1983. She continues to do well.

All of the patients with benign conditions in whom the cervical esophagus has been replaced with jejunum have done very well, indeed.

May I ask whether there has been a problem with vascular thrombosis, particularly on the venous side? There must be technical problems associated with mobilizing such long segments.

DR. EDWARD F. PARKER (Closing discussion): I want to thank the discussants first.

Dr. Haller first mentioned the question of carcinoma in the transplanted colic patch. We have had no experience with it. I doubt if sufficient time has elapsed to see whether or not carcinoma would develop, and we have nothing more to say.

How long a segment has been patched? In this series, it has been up to 8 and 10 cm in the thoracic esophagus.

I can't equal Dr. Campbell's histrionics or illustrations of liquid caustics, but in connection with the liquids, we would only have to say that we hope that legislation might control some of it, including some of the alcoholic beverages we are invited to drink at times.

On the long-term follow-up, there hasn't been enough time to see whether or not carcinoma would develop, or whether or not there is going to be any carcinoma in any residual burn of the esophagus which might not present enough scar to excise at the time of operation. Grossly one leaves no scar.

As far as carcinoma and scar are concerned, at the Medical University of South Carolina hospitals, in over a thousand patients, we have seen very, very few that were associated with scars. In one that I remember in particular, the patient had a scar, but the carcinoma did not arise in the scar, so I don't know the causal relation between scar and carcinoma in our cases.

Now, we might add that surgeons have long had access to the cervical and the abdominal esophagus, but prior to the 1975 publication of Hecker and Holman and a subsequent similar description by Othersen and Smith in 1985, restoration of the ability to swallow usually has been restricted to one of several methods described by Dr. Othersen, and also to the use of transplantation of fascia, either adjacent or distant. Even the fascia lata has been used in the past to fill-in a defect in the esophagus.

Since the advent of the colic patch method used as described, we have had one case in which a free pericardial patch was used. The initial result was satisfactory, but the late, unsatisfactory, and the patient may become a candidate for the colic patch technique of repair if the recurrent stricture does not respond to hydrostatic dilatations.

We have also used a free loop of jejunum, which Dr. Jurkiewicz has illustrated so beautifully in past years, for transplantation to the neck with anastomosis of the artery and vein to corresponding cervical vessels, and a fastening of the patch as described. The result has been extremely good.

As far as the various liquids that cause trouble are concerned (not so much in children, but in adults, especially those suicidal or accidental), we have no idea what they drink because many times they are drunk and they don't know, either. The amount of injury that can be caused is unbelievable. In one adult, the last one we operated on, not only was the esophagus destroyed, the stomach was destroyed also. At the time of gastrectomy, the lumen was literally reduced to a size that would not accommodate anything more than my thumb. We ended by having to do a total esophagogastrectomy and using a colic transplant between the cervical esophagus and the duodenum. Then we had to do secondary operations later, because the proximal end of the colic patch became necrotic, probably due to a pectus recurvatum at the manubrial end. The pressure, I think, caused the necrosis. Finally, we excised the manubrium and used a tubular jejunal graft, again as described by Dr. Jurkiewicz, between the cervial esophagus and the remaining viable colic transplant. The end result has been most satisfactory.

Prior to 1975 and since, we have found in the literature no mention of any direct operation on a stricture of the thoracic esophagus by luminal enhancement by interposition of a loop of colon that has been incised longitudinally on its antimesenteric border. This method allows the colic loop to serve as a patch, its corners trimmed to match the contour of the esophageal defect to close the longitudinal, widely gaping incision with very gratifying results.

Comparison of Percutaneous Endoscopic Gastrostomy with Stamm Gastrostomy

JOHN P. GRANT, M.D.

In a review of 125 percutaneous endoscopic gastrostomies (PEG) and 88 Stamm gastrostomies performed at Duke University Medical Center since 1978, the average operating room time for PEG (50 ± 20 min) was shorter than for Stamm (96 ± 26 min) ($p < 0.0001$). General anesthesia was administered in only 13% of PEG placements compared with 64% of Stamm gastrostomies. The cost of PEG was about $1000 less than for Stamm gastrostomies. The average time after surgery until use of the feeding tube was 1.8 days for PEG compared with 3.4 days for Stamm ($p < 0.0001$). The overall complication rate after PEG was 8.8% (4.0% major) compared with 23.9% for Stamm gastrostomies (10.2% major) ($p < 0.005$). PEG reduces operative time, necessity for general anesthesia, expense of insertion, incidence of complications, and requires less recovery time before use. PEG is the procedure of choice for gastric feeding access.

From the Department of Surgery, Duke University Medical Center, Durham, North Carolina

EGEBERG IS CREDITED WITH first expressing the concept of a gastrostomy in 1837. Sedillott successfully performed gastrostomies in dogs in 1839 but failed in three attempts in humans in 1846 with all three patients dying. It was not until 1876 that Verneuil performed the first successful gastrostomy in humans. Since then, numerous modifications have been suggested including a serosal tunnel by Witzel in 1891, permanent gastrostomy tubes by Janeway and Beck-Jianu in the early 1900s, and a valved gastric tube by Glassman in 1939. The most successful and most commonly used technique today, however, was proposed by Stamm in 1894 using concentric purse string sutures to invaginate the serosa about a tube passed into the stomach. Although relatively simple to perform, the Stamm gastrostomy has been associated with a significant incidence of complications including wound infections, gastric bleeding, skin erosions with leakage about the tube, pain at the exit site, anesthetic complications, and occasional death. In an extensive review by Mamel, 264 complications were seen in 1438 Stamm gastrostomy placements (18.4%) with 9.8% of major and 8.7% of minor complications.[1] These complications are due in part to the use of general anesthesia, need for a laparotomy in often malnourished patients, and technical difficulties with placement and securing of the purse string sutures. One publication by Smith and Farris in 1961 is notable for its large number and unusually good experience placing 2512 Stamm gastrostomies with only nine complications (0.4%).[2]

In 1980, Gauderer et al. described a technique for endoscopic placement of a feeding gastrostomy tube, which could be performed under local anesthesia and did not require a laparotomy.[3] In a limited but growing experience, a complication rate one third of that of Stamm gastrostomy has been reported, comprised mainly of tube exit site infections and aspiration pneumonias.[1,4,5] This review was undertaken at Duke University Medical Center to compare results of percutaneous endoscopic gastrostomy with Stamm gastrostomy with respect to operative time, use of general anesthesia, incidence of complications, time prior to use after placement, and cost.

Methods

The records of all patients who underwent placement of a feeding gastrostomy by the author from November 1978 through November 1987 were reviewed. Early in the series all patients had a Stamm gastrostomy placed. As experience with percutaneous endoscopic gastrostomy increased, most patients received a percutaneous endoscopic gastrostomy. No randomization was performed. Patients with acute peritonitis, delayed gastric

Submitted for publication: December 10, 1987.

emptying, significant esophageal reflux, or cirrhosis with portal hypertension, ascites, or esophageal or gastric varices, were excluded. Prior abdominal surgery was not an exclusion factor unless the surgery had involved a partial or total gastrectomy.

The following standard technique was used for Stamm gastrostomy. A 6–8-cm midline incision was placed and a 22–28 F Silastic Malecot gastrostomy tube inserted high on the anterior gastric wall using 2–3 concentric purse string silk sutures to invaginate the gastric wall about the tube. The tube was brought out a separate stab wound in the left upper quadrant and the stomach was sewn to the abdominal wall at the tube exit site. The midline incision was closed primarily. The tube was connected to straight drainage. When drainage was minimal and bowel sounds were normal, the tube was clamped and bolus gastric feedings begun.

Percutaneous endoscopic gastrostomies were placed using a modification of the technique of Gauderer et al.[3] Patients were given 10 mg of diazepam as a preoperative sedative when necessary and 1 g of cefazolin on call to the operating room. The abdomen was prepared for surgery with povidone-iodine soap, alcohol, and povidone-iodine solution and draped in a sterile fashion. A pediatric gastroscope was introduced into the stomach, carefully observing the esophageal lumen during passage to assure no strictures or other abnormalities. The stomach and pylorus were also examined to rule out the presence of varices or stricture. The stomach was insufflated with air through the gastroscope until it was fully distended. The light of the scope was directed anteriorly and the lights in the operating room dimmed, allowing visualization of the light through the abdominal wall. The presence of a sharp, circular light image assured that there was no intervening bowel or liver between the stomach and the anterior abdominal wall. The point of maximal light transillumination was selected for the gastrostomy site and was usually about one third of the distance along a line from the left costal margin at the midclavicular line to the umbilicus. Care was taken to always place the exit site at least 4 cm from the costal margin to avoid site irritation. If necessary, the site was adjusted so that palpation with a single finger at the site was clearly seen by the endoscopist as an indentation of the anterior stomach wall confirming apposition of the stomach to the abdominal wall. Occasionally in obese patients or patients with scarred abdominal walls as with prior burns, the light did not transilluminate. In all cases, however, palpation resulted in a clear indentation of the stomach wall and the procedure was continued. If neither sign is present, the procedure should be abandoned. The skin at the selected exit site was infiltrated with 1% Xylocaine* and an incision exactly 1.5 times wider than the diameter of the gastrostomy tube was placed. A larger incision is associated with poor healing, skin irritation and, occasionally, tube erosion. A smaller incision drains poorly and leads to cellulitis at the exit site and occasionally a subcutaneous abscess or fasciitis. A 16-gauge Argyle Medicut "R" catheter was introduced through the incision and advanced into the stomach directing the tip toward the endoscope light (Sherwood Medical Industries, St. Louis, MO). A snare was passed through the endoscope and placed over the end of the Medicut catheter. A #1 nylon suture was passed through the catheter and grasped with the snare. The endoscope and suture were then drawn out through the esophagus and mouth. The Medicut catheter was removed from the abdominal wall and the end of the suture exiting from the mouth tied to the end of a 16 F Glasser Percutaneous Endoscopic Gastrostomy Tube (Biosearch Medical Products, Inc., Sommerville, NJ). The gastrostomy tube was marked with a marking pen at 1-cm intervals from its end for a distance of 4 cm (Fig. 1). The suture material and gastrostomy tube were then lubricated with Neosporin ointment™ (Burroughs Wellcome) and the suture withdrawn from the abdominal wall drawing the gastrostomy tube through the mouth, down the esophagus and out the abdominal wall. The tube was withdrawn until the inner disk retainer drew the stomach tightly against the abdominal wall and an appropriate number of markings for the estimated abdominal wall thickness were seen. The use of markings on the gastrostomy tube permitted omission of the second endoscopic procedure initially proposed by Gauderer et al.[3] to assure the tube was tight against the gastric wall. Eliminating the second endoscopic procedure reduces risks of aspiration and esophageal injury. The outer retainer disk was then slid over the gastrostomy tube and secured tightly against the skin to maintain apposition of the stomach to the abdominal wall. The end of the gastrostomy tube was cut to proper length, an adaptor placed, and the tubing connected to straight drainage. Patients were returned to their hospital beds without going to the recovery room. They were given 1 g of cefazolin every 8 hours for two doses. The PEG tube was connected to straight drainage. When drainage was minimal and bowel sounds were normal, the tube was clamped and bolus gastric feedings were begun. At 48 hours the dressing was removed from the catheter site and the outer disk loosened to avoid erosion of the stomach or skin.

Operating room time from patient entry until departure was recorded along with the recovery room charges, material costs, and professional fees. Patients were followed for 96 ± 164 days (PEG) and 237 ± 392 days (Stamm) to determine the time until use for feeding and the incidence of complications. Statistical analysis was by Student's t-test and chi square analysis.

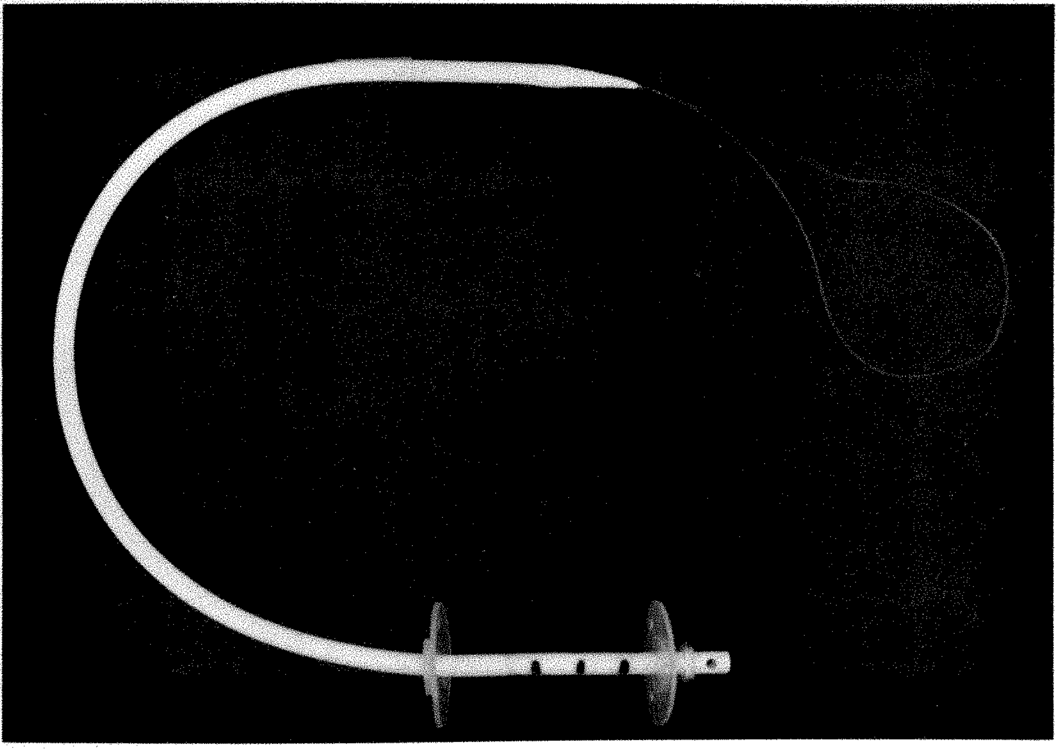

FIG. 1. Percutaneous gastrostomy tube. Note markings at end allowing estimation of distance of stomach from abdominal wall during placement. These markings allow placement by single endoscopy technique.

Results

From July 1981 through November 1987, 125 patients had percutaneous endoscopic gastrostomy tubes placed. In only two cases was the procedure abandoned because endoscopy could not be done. Experience in these patients was compared with 88 Stamm gastrostomies placed from November 1978 through November 1987. Table 1 compares population characteristics. The major indication for gastrostomy placement was altered mental status due to cerebral vascular accidents, primary neurological diseases, and head trauma (64%). Thirty-six per cent had difficulty swallowing due to head and neck tumors or their treatment. The average ASA anesthetic risk for PEG was 3.4 and for Stamm was 3.1 (NS) reflecting multiple other medical problems (Tables 1 and 2). The preference for percutaneously placed gastrostomy tubes later in the series is evident from 1986 and 1987 data that indicated 98 PEG but only 12 Stamm gastrostomies were placed.

The average operating room time required to place a percutaneous endoscopic gastrostomy was 50 ± 20 minutes compared with that for Stamm gastrostomy of 96 ± 26 minutes ($p < 0.0001$). There was a reduction in time for placement of percutaneous endoscopic gastrostomies as experience and expertise increased with an average time of 38 ± 14 minutes for the last 62 tubes placed in 1987. The reduced operating room time for PEG and little need for the recovery room resulted in a savings compared with Stamm gastrostomy of almost $1000 per case. Only 16 percutaneous endoscopic gastrostomies (13%) were done under general anesthesia. Of those, most received general anesthesia either because of other procedures performed simultaneously or for patient comfort in the presence of a tracheostomy. On the other hand, it was elected to perform 57 Stamm gastrostomies (64%) under general anesthesia due to poor abdominal relaxation or patient cooperation. The average time until use of percutaneous endoscopic gastrostomy tubes for enteral feeding, 1.8 ± 0.8 days, was less than that for Stamm gastrostomy tubes, 3.4 ± 2.0 days ($p < 0.0001$). Days to discharge were highly variable (PEG = 55 ± 123 days *vs.* Stamm 26 ± 40 days, $p = 0.117$) and were determined by the patients' primary illness rather than the type of gastrostomy.

Complications after percutaneous endoscopic gastrostomy occurred in 8.8% of patients (Table 3). Two aspiration pneumonias occurred owing to endoscopy, both of which resolved with antibiotics. The one episode of gastric hemorrhage was minor, resolving spontaneously without transfusion. Four of the six episodes of gastrostomy tube exit site infections were minor. Two had significant cellulitis and required antibiotic therapy and drainage. Most exit site infections occurred early in the series and were due to a small skin incision with inadequate drainage about the tube. Only one exit site infection has occurred in the past 98 placements after incisions measuring 1.5 times the diameter of the gastrostomy tube were routinely used and perioperative antibiotics were given. One feeding tube was dislodged by a

confused patient during the first postoperative night. The patient was taken to the operating room immediately and had a Stamm gastrostomy placed. One tube had transient leakage of gastric juice about it. Five tubes were removed when no longer needed without difficulty. No gastrocutaneous fistula developed.

Thirty-one patients had percutaneous endoscopic gastrostomy tubes placed after prior upper (17 patients) and lower abdominal procedures (14 patients) (Table 4). In each case the endoscope light was clearly visualized through the abdominal wall and indentation of the stomach with external pressure at the exit site was clearly visualized. Three morbidly obese patients underwent PEG. Although no light transillumination was seen, palpation was seen to indent the anterior stomach wall. No operative complications were seen in any of these patients.

Complications after placement of Stamm gastrostomies occurred in 23.9% of patients (Table 5). This incidence was significantly higher than for PEG ($p < 0.005$). Seven wound infections occurred requiring partial (3) or complete (4) opening of the wound for debridement and packing. Four instances of tube exit site infections resulted in significant skin erosion and leakage of gastric contents. Intensive local wound care and insertion of a larger tube was required. Leakage of gastric juice at the tube exit site occurred in four additional patients. In one patient it could not be controlled and the gastrostomy tube was removed and replaced with another done by percutaneous endoscopic technique. The old gastrostomy site did not heal and was finally closed surgically. One patient had transient bleeding from the stomach and one patient had the tube withdrawn at postoperative day 3. The tube was successfully replaced under fluoroscopic guidance. Two patients had severe pain at the gastrostomy site and required intermittent use of narcotic analgesics. One patient had gastric outlet obstruction from the tip of the gastrostomy tube lodging in the pylorus.

Eventual outcome of all patients is depicted in Table 6. No patient died in this series as a complication of placement of the feeding gastrostomy. The high death rate (30.0%) relates to the severity of illness of these patients.

Discussion

Previous reports have documented reduction in operating room time and cost when percutaneous endoscopic gastrostomies are performed compared with standard gastrostomies by laparotomy.[1,6-9] The reduction in total operating room time and little need for the recovery room in this series reduced patient charges by

about $1000. The actual endoscopic procedure takes only 10–15 minutes with the remainder of the 30–40 minutes required for patient transfer and establishment of monitoring and intravenous access.

Some physicians advocate placement of percutaneous gastrostomy tubes in the endoscopy suite rather than in the operating room. In selected patients this may be appropriate and would further reduce costs. Most of our patients, however, had significant medical illnesses including poor pulmonary toilet, hypertension, and cardiac disease, and it was believed that for optimal safety the operating room environment was required where airway management could be easily performed and cardiac arrhythmias and arterial oxygen saturation monitored and quickly addressed if necessary. In four of our patients, arterial oxygen saturation by pulse oximeter fell below 90% during endoscopy but was easily treated by adjusting the position of the head, oral suctioning, or administering supplemental oxygen. Oxygen desaturation may go unnoticed in an endoscopy suite possibly contributing to pre-existing altered mental status. The reduced surgical trauma of PEG resulted in a significant decrease in postoperative gastrointestinal ileus allowing earlier institution of gastric feeding. Although abdominal distention due to insufflation of air was common, bowel sounds were usually present within 24 hours of PEG placement and the gas passed through quickly. Abdominal x-rays were not routinely done after PEG placement but when done there was no evidence for pneumoperitoneum.

Only two operative complications of PEG were encountered in this study, both aspiration pneumonias. One possible advantage of the single endoscopic method described herein is the avoidance of potential complications associated with passage of the endoscope a second time to confirm proper tension on the gastrostomy tube. Manufacturers of commercially available percutaneous endoscopy tubes have yet to permanently mark their catheters; however, sterile marking pens provide a satisfactory alternative.

A list of potential complications associated with percutaneous gastrostomy placement (Table 3) suggests to this author that the procedure should be performed by surgeons rather than gastrointestinal endoscopists. Most complications require surgical management and would be most quickly recognized and expeditiously handled by the surgeon.

The safety of placing percutaneous endoscopic gastrostomy tubes in the presence of prior abdominal surgery, suggested by Stellato et al.,[10] is supported by this series. As long as the endoscope light clearly transilluminates through the abdominal wall and/or external pressure at the proposed gastrostomy exit site results in clear indentation of the gastric wall as seen through the endoscope, preferably both, it is safe to proceed without fear of passage through either the liver or interposed bowel.

Conclusions

Percutaneous endoscopic gastrostomy reduces operative time, necessity for general anesthesia, expense of gastrostomy placement, incidence of complications, and requires less recovery time before use for enteral feedings. This study supports the use of percutaneous endoscopic gastrostomy as the procedure of choice for gastric feeding access even in patients with prior abdominal surgery. Stamm gastrostomies should be placed when a laparotomy is performed for other reasons or when gastroscopy is not possible or advisable.

DISCUSSION

DR. NORMAN HALPERN (Birmingham, Alabama): With any new technique or technology we should ask two questions.

Will it perform a new or different task, or will it better perform an old task? In this case there is nothing really new or different about creating a tube gastrostomy. On the other hand, I am personally convinced that this is a totally superior method for getting the job done.

My experience with 63 patients at UAB is similar to Dr. Grant's larger, carefully reviewed series. I appreciated having a copy of his manuscript and agree with all of his cautions regarding careful assessment of indications and contra-indications, thoughtful attention to the matter of patient safety and monitoring, and to the technical details of the procedure.

An additional application of endoscopic gastrostomy occurred in three of my patients and has been reported by others. That is, for the patient with intra-abdominal carcinomatosis having had repeated episodes of small bowel obstruction and felt to have an unlikely chance of benefit from further surgery. Enteric decompression combined with home parenteral nutrition achieved excellent palliation for periods of 1, 6, and nearly 8 months in these three patients.

I do appreciate the chance to comment and offer support for a procedure that I think really does offer improvement in patient care.

DR. HENRY L. LAWS (Birmingham, Alabama): It appears that Dr. Halpern and I almost have to go as a team.

I think Dr. Grant is to be commended for his critical evaluation of the data on a large number of gastrostomies. From what we heard this morning, this topic is very appropriate, since the first paper given 100 years ago was on gastrostomy.

It is actually disconcerting to me that we are still trying to perfect the operation.

I feel this lowly operation does not receive the attention it deserves. I would differ with Dr. Grant and with my colleague, Dr. Helpern, to some extent in that I think the stapled Janeway gastrostomies are superior to Stamm gastrostomies over the long haul.[1,2]

(Slide) This series was collected by Dr. Fred Swartzendruber, one of our colleagues. What it indicates is that the late complications of Stamm gastrostomies, of which I feel the percutaneous endoscopic gastrostomy is a variant, include late tube malfunction, exit site problems, and so forth, which can be very trying. Neither of these are lined with mucosa. On the other hand, the problems we had with Janeway gastrostomy were very minimal and were minor in every instance.

I would like to ask Dr. Grant how long he followed his patients and how they have been faring over the long haul.

2. Swartzendruber FD, Laws HL. The superior feeding gastrostomy. Am Surg 1982; 48:276–278.

DR. LEWIS M. FLINT, JR. (Buffalo, New York): I would like to address the use of feeding gastrostomy in a select group of neurologically disabled patients, those who are comatose or obtunded, and to raise the question of whether this operation, regardless of the technique, is indicated and whether it achieves the objectives that we wish it to achieve in the long term.

We recently reviewed 87 comatose or severely obtunded patients in our unit in which feeding gastrostomy was performed for two basic indications, for example, to provide access for nutritional support and, in some cases, to reduce the risk of aspiration pneumonia.

We found that the operation did not, over a two-year follow-up, achieve either objective and that not only was the risk of aspiration pneumonia that existed pregastrostomy not reduced, but about 30% of those patients in whom no aspiration pneumonia could be documented preoperatively developed it postoperatively over the two-year period.

The one-year mortality in our group was 34%, most of this as a result of aspiration pneumonia.

According to our clinical experience, then, gastrostomy did not achieve the objective of reducing the risk of aspiration pneumonia. Neither did it achieve the objective of providing nutritional support, since we could not document nutritional benefit in a single one of our patients in this particular group.

Since we can now acquire and maintain enteral access by the transnasal soft tube technique, using the transpyloric tubes in better than 95% of the patients, I would ask Dr. Grant to comment on the indications, particularly in this select group of patients, and ask him two additional questions. Was the objective of gastrostomy achieved, long-term? And in patients with aspiration pneumonia, does he consider the addition of complementary tracheostomy?

DR. JOHN P. GRANT (Closing discussion): Dr. Halpern has employed percutaneous gastrostomies in a population in which we have little experience: those patients who have distal bowel obstruction and require gastric decompression. I recall several cases where I have placed a Stamm gastrostomy during laparotomy when a diagnosis of carcinomatosis was made to establish proximal decompression. I have been rather disappointed with the clinical benefits, most of the patients dying rather quickly after the operative procedure, and I congratulate Dr. Halpern on his more favorable results.

Dr. Laws, we have very little experience with the Janeway gastrostomy. It is interesting to hear that you feel it is superior to the Stamm gastrostomy.

We have followed our patients on the average for 100 days after percutaneous gastrostomy, and about 200 days after the Stamm gastrostomy. As many patients have gone to distant hospitals or nursing homes, accurate follow-up has been difficult, as you might expect. We know at least 20% have died from their primary disease process. We know another 12% have improved and their feeding tubes have been removed. The remainder have been lost to follow-up after they left the hospital.

Dr. Flint, gastrostomies, I think, are always going to be associated with aspiration pneumonia. It is a complication that is very difficult to avoid in a patient who is not very alert and who is often reclining at the time of feeding, as well as between feedings. It is therefore difficult to distinguish aspiration of tube feedings from aspiration of saliva in patients who have difficulty swallowing. We have had great difficulty sending patients to nursing homes with either a nasojejunal feeding tube or with a feeding jejunostomy. It requires a level of care that they are unprepared (and often unwilling) to assume. In patients who have had repeated bouts of aspiration pneumonia in the hospital, however, I have elected on occasion to place both a gastrostomy for decompression and jejunostomy for feeding, and have been pleased with the results. Another approach that several of our surgeons have taken is to perform both a Stamm gastrostomy and a Nissen fundoplication simultaneously, which, although it may not prevent aspiration of saliva, at least prevents the reflux.

Hemodynamic Dysfunction in Obesity Hypoventilation Syndrome and the Effects of Treatment with Surgically Induced Weight Loss

HARVEY J. SUGERMAN, M.D.,* PAUL L. BARON, M.D.,* R. PAUL FAIRMAN, M.D.,† CHARLES R. EVANS, M.D.,‡
and GEORGE W. VETROVEC, M.D.‡

Obesity hypoventilation syndrome (OHS), defined as a $PaO_2 \leq 55$ mmHg and/or $PaCo_2 \geq 47$ mmHg, was found in approximately 8% of morbidly obese patients undergoing gastric surgery for morbid obesity and was frequently associated with clinically significant pulmonary hypertension and cardiac dysfunction. Forty-six morbidly obese patients, 26 with and 20 without OHS, underwent preoperative pulmonary artery catheterization. Although the two groups had similar values for percent ideal body weight, blood pressure, and cardiac index, the OHS patients had significantly higher mean pulmonary artery pressures (PAP), $p < 0.0001$, and pulmonary artery occlusion pressures (PAOP), $p < 0.01$. Eighteen OHS patients were restudied 3–9 months after gastric surgery. PaO_2 increased from 50 ± 10 to 69 ± 14 mmHg, $p < 0.0001$, and $PaCO_2$ decreased from 52 ± 7 to 42 ± 4 mmHg, $p < 0.0001$), after the loss of 42 ± 19% excess weight. These changes were associated with significant decreases in PAP (from 36 ± 14 to 23 ± 7 mmHg, $p < 0.0001$) and PAOP (from 17 ± 7 to 12 ± 6 mmHg, $p < 0.01$). Significant correlations were noted between PAP and PAOP ($r = +0.8$, $p < 0.0001$) and PAP and PaO_2 ($r = -0.6$, $p < 0.0001$). Both left ventricular dysfunction, defined as a PAOP ≥ 18 mmHg, as well as pulmonary artery vasoconstriction, defined as PAEDP > 5 mmHg above PAOP, contributed to pulmonary hypertension in OHS patients. In conclusion, weight loss after gastric surgery for morbid obesity significantly improved arterial blood gases and hemodynamic function in OHS patients.

University, Richmond, Virginia

In a recent study, 12% of patients who underwent gastric surgery for morbid obesity had respiratory insufficiency of obesity.[1] Of these, one third had obesity hypoventilation syndrome (OHS) alone, one third had obstructive sleep apnea syndrome (SAS) alone, and the remaining third had both OHS and SAS, as in the Pickwickian syndrome.[2] Heart failure has been a prominent feature of patients with OHS.[2-10] In addition, patients with severe OHS are at risk of having a pulmonary embolus, which is often fatal.[11] In previous studies, we have shown that weight reduction in patients with respiratory insufficiency of obesity was associated with significant improvements in the severity of SAS, arterial hypoxemia, hypercarbia, polycythemia, and restricted lung volumes.[1,12] We postulated that hemodynamic dysfunction would be similarly improved. This study used pulmonary artery catheterization to compare hemodynamic function in morbidly obese patients with and without OHS as well as to determine the hemodynamic effects of weight reduction after gastric restrictive surgery in OHS patients.

Materials and Methods

Patient Selection

Patients were accepted for weight reduction surgery if their weight exceeded ideal body weight by more than 100 pounds.[13] Two groups of patients were studied: a control group with no evidence of respiratory compromise and an OHS group with either OHS alone or OHS combined with SAS. Baseline arterial blood gases were obtained in all patients on room air at the time of admission to the hospital. OHS was defined as a $PaO_2 \leq 55$ mmHg and/or a $PaCO_2 \geq 47$ mmHg. Patients with a history suggestive of SAS (*i.e.*, severe daytime somnolence, profound snoring, headache upon awakening,

restless sleep, or frequent nocturnal awakening) underwent preadmission sleep polysomnography. SAS was diagnosed if multiple apneic or hypopneic episodes were present. Morbidly obese patients who had no evidence of cardiopulmonary disease, systemic hypertension, or diabetes mellitus were asked to enter the control arm of the study. For each patient, per cent ideal body weight (%IBW) was calculated as the ratio of preoperative weight divided by ideal body weight. The study was approved by the Committee on the Conduct of Human Investigation and the Clinical Research Center at the Medical College of Virginia, Virginia Commonwealth University.

Cardiopulmonary Evaluation

Control patients underwent pulmonary artery catheterization in the cardiac catheterization laboratory using flow-directed, thermistor-tipped balloon catheters and fluoroscopic guidance. OHS patients underwent preoperative pulmonary artery catheterization in the Surgical Intensive Care Unit without fluoroscopic guidance. Three to nine months after gastric surgery, 18 OHS patients underwent repeat pulmonary artery catheterization in the Clinical Research Center.

Pressure transducers were zeroed and balanced at the midaxillary line. The pulmonary artery catheters were advanced with the balloon inflated until an "occlusion" tracing was observed. Balloon deflation revealed a pulmonary artery pressure tracing. All pressures were measured directly from the oscilloscope at the end of expiration. The pressure measured with the balloon inflated and the appropriate tracing on the oscilloscope was called the pulmonary artery occlusion pressure (PAOP). The central venous pressure (CVP) was measured from the superior vena caval port of the pulmonary artery catheter. Mean pulmonary artery pressure (PAP) was calculated by determining one third of the difference between the pulmonary artery end-diastolic pressure (PAEDP) and the pulmonary artery systolic pressure and adding this value to the PAEDP. The mean systemic arterial pressure (SAP) was calculated with the same formula from the systolic and diastolic systemic pressures measured with an extra large blood pressure cuff.

Pulmonary hypertension was defined as a PAP $\geq$ 20 mmHg. Pulmonary hypertension was considered to be secondary to left ventricular dysfunction when the PAOP was $\geq$ 18 mmHg and due to pulmonary artery vasoconstriction when the PAEDP exceeded PAOP by $>$ 5 mmHg, regardless of the latter's value. Thermodilution cardiac output was calculated with a Gould-Statham cardiac output computer (model #SP 1453, Gould Inc., Oxmore, CA 93430). Cardiac index (CI) was calculated by dividing cardiac output by body surface area using a standard nomogram. Pulmonary vascular resistance index (PVRI) was calculated by the formula: $[(\mathrm{PAP} - \mathrm{CVP}) \div \mathrm{CI}] \times 79$ and systemic vascular resistance index (SVRI) by the formula: $[(\mathrm{SAP} - \mathrm{PAOP}) \div \mathrm{CI}] \times 79$.

Surgical Procedures, Pre- and Postoperative Management

Over the course of the study (January 1979 through January 1987), a number of different weight reduction procedures were tried. Several of these procedures are now known to be ineffective,[14] including the single-row of staples, unreinforced central stoma, horizontal gastroplasty,[15] and the Gomez gastroplasty.[16] Since June 1982, we have used only vertical banded gastroplasty[17] or Roux-en-Y gastric bypass.[18,19] Patients who failed one of the gastroplasty procedures were offered conversion to gastric bypass, which we have found to provide significantly greater weight loss, especially for patients addicted to sweets.[20] This report will focus on pulmonary artery catheterization data, as the effect of the different procedures on weight reduction[14,20] and pulmonary function[1,12] have been evaluated in previous publications.

Initially, patients with severe SAS or apnea-induced cardiac arrhythmias underwent tracheostomy at the time of gastric surgery. Since 1985, an attempt has been made to treat all SAS patients with nocturnal nasal continuous positive airway pressure (CPAP).[21] Tracheostomy was only performed if the patient could not tolerate nasal CPAP.

Intermittent sequential venous compression boots were used in all patients during surgery and until fully ambulatory to reduce the incidence of thrombophlebitis and pulmonary embolism.[22] After operation, patients were nursed in the reverse Trendelenburg position to maximize pulmonary function.[23] Increased venous stasis from this position made the use of intermittent venous compression boots even more important. In patients with severe pulmonary hypertension (PAP $\geq$ 40 mmHg), a Greenfield® vena caval filter (7 patients) or a Miles® vena caval serrated clip (1 patient) was inserted because of the increased risk of a fatal pulmonary embolism in patients with respiratory insufficiency of obesity[12] as well as the documented danger of fatal pulmonary embolism in patients with primary pulmonary hypertension.[24]

Anesthetic induction was performed with sodium pentothal following muscle paralysis with succinyl choline. At least two anesthesia personnel were present. One was responsible for elevating the jaw, hyperextending the neck, and assuring a tight fit of the ventilation mask over the mouth and nose after insertion of an oral airway. The second person manually compressed the ventilation reservoir bag with both hands because these patients have very low respiratory system compliance. After ventilation with 100% oxygen for several minutes, intubation was attempted. If difficulties were encountered, these steps were repeated until the patient was sucessfully intubated. A radial arterial line was inserted for systemic pressure monitoring and periodic arterial blood gas analysis. A digital pulse oximeter was used to monitor the adequacy of arterial oxygenation from moment to moment.

All control patients were extubated in the recovery room and none required intensive care unit management after surgery. OHS patients were ventilated with a volume ventilator, 1500 cc tidal volume, 5 cm H_2O positive end-expiratory pressure, an F_IO_2 to maintain the PaO_2 above 60 mmHg, and a respiratory rate to maintain the $PaCO_2$ at 40 mmHg. The patients were extubated when they were able to generate −40 cm H_2O inspiratory pressure, 1500 cc vital capacity, and blood gases had returned to preoperative values with a T-piece and room air.

Data Analysis

Data are presented as the mean ± SD. Statistical analyses were performed using Student's t-test for paired or unpaired values, as appropriate. Equal variance was assumed for the latter. P values < 0.01 were considered significant. Pearson correlation coefficients were calculated for preoperative data to evaluate significant correlations. Even though statistically significant, correlations were not considered clinically relevant unless the correlation coefficient (±) was >0.6.

Results

Preoperative Data

Forty-six patients were studied: 20 control and 26 OHS. Of the patients with OHS, nine had OHS alone and 17 had both OHS and SAS. The OHS and control groups had similar preoperative %IBW (Table 1). The OHS group was significantly older, had a greater percentage of men, and had a significantly greater number of patients with an underlying pulmonary disease usually secondary to excessive smoking. The mean preoperative hemoglobin level in the OHS patients was 14.9 ± 2.6 g/dl. Twelve of the 26 OHS patients had a hemoglobin level greater than 16.0 g/dl. Two OHS patients had hemoglobin levels greater than 18 g/dl. Two female OHS patients with dysfunctional uterine bleeding had hemoglobin values less than 11 g/dl and one OHS patient with a Duke's A carcinoma of the cecum had a hemoglobin level of 7.3 g/dl. This patient underwent combined right colectomy and gastric bypass without postoperative complications. None of the control patients had a hemoglobin level greater than 14.4 g/dl.

TABLE 1. *Demographics*

	% IBW	Age (years)	% Men	% Black	% Additional Pulmonary Problem†
Control	229 ± 47	36 ± 9	15	60	10
OHS	225 ± 46	44 ± 11*	54	54	81*

* $p < 0.01$.

† Smoked ≥ 1 pack cigarettes/day except two OHS patients who had asthma.

As expected, the PaO_2 in the OHS group was lower (54 ± 10 *vs.* 84 ± 12 mmHg, $p < 0.001$) and the $PaCO_2$ higher (51 ± 6 *vs.* 39 ± 3 mmHg, $p < 0.001$) than the control group. The SAPs of the two groups were comparable: 101 ± 13 mmHg for control and 100 ± 13 mmHg for OHS. However, the PAP and PAOP were significantly greater in the OHS group (Fig. 1). Seven of 20 control patients had PAP ≥ 20 mmHg; however, none had a PAP above 30 mmHg. No control patients had a PAOP ≥ 18 mmHg. Of the 26 OHS patients, 23 had a PAP ≥ 20 mmHg and in eight it was ≥40 mmHg. Fourteen of the 23 OHS patients with pulmonary hypertension had left ventricular dysfunction, defined as PAOP ≥ 18 mmHg (Fig. 2). Two patients had a PAOP ≥ 30 mmHg and in one, the PAOP was 40 mmHg. The PAEDP was >5 mmHg above the PAOP in 15 of the 23 patients with pulmonary hypertension, implying significant pulmonary artery vasoconstriction (Fig. 2). Six patients had both a PAOP ≥ 18 mmHg and PAEDP 5 mmHg greater than their PAOP (Fig. 2).

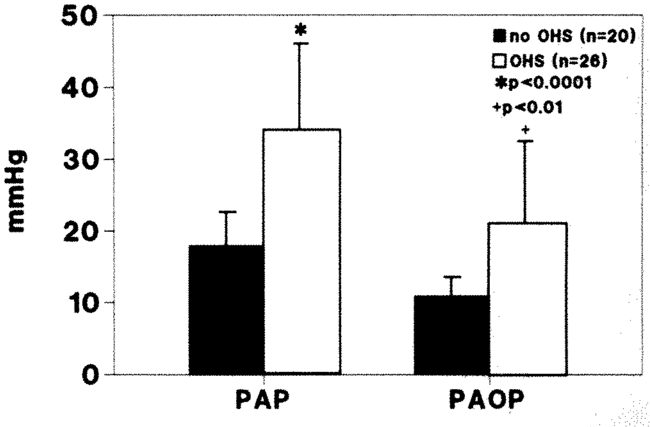

FIG. 1. Significantly higher mean pulmonary artery pressure (PAP) and mean pulmonary artery occlusion pressure (PAOP) in morbidly obese patients with, than in morbidly obese controls without, obesity hypoventilation syndrome (OHS).

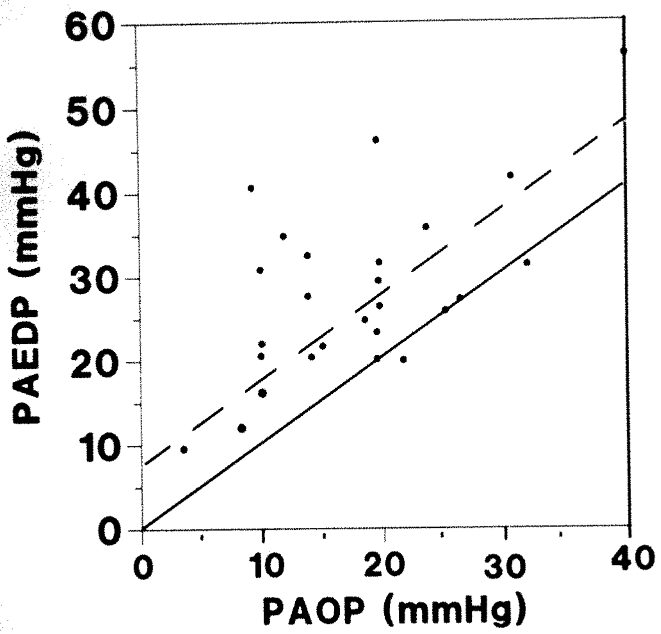

FIG. 2. Comparison of pulmonary artery and diastolic pressure (PAEDP) and pulmonary artery occlusion pressure (PAOP) in obesity hypoventilation syndrome (OHS). Solid line for PAEDP = PAOP. Dashed line for PAEDP 5 mmHg > PAOP.

The preoperative cardiac index was not significantly different between the control and OHS patients, 3.2 ± 0.6 *versus* 3.5 ± 0.6 L/min/m^2, respectively. The systemic vascular resistance index was also not significantly different between the control and OHS patients, 891 ± 183 *versus* 767 ± 223 dynes/cm^{-5}/m^2, respectively. As expected, the pulmonary vascular resistance index was significantly ($p < 0.01$) greater in the OHS group (258 ± 137 dynes/cm^{-5}/m^2) than the control group (147 ± 63 dynes/cm^{-5}/m^2).

The PaO_2 was inversely correlated ($p < 0.0001$) with the PAP, but the correlation coefficient ($r = -0.6$, $r^2 = 0.4$) was not as high as the correlation ($p < 0.0001$) between the PaO_2 and the PAOP ($r = -0.8$, $r^2 = 0.6$). There was no correlation between preoperative hemoglobin and PAP, PAOP, or PaO_2 in the OHS patients.

Cardiopulmonary Effects of Weight Loss in the OHS Patients

Eighteen of the 26 OHS patients underwent repeat pulmonary artery catheterization 3–9 months after gastric surgery for morbid obesity. With regards to the eight patients who were not restudied, four refused, one was lost to follow-up, two had normal preoperative studies, and one patient died suddenly 5 weeks after surgery. This 27-year-old black woman weighed 472 lbs (255 %IBW). Her preoperative PaO_2 and $PaCO_2$ were 50 and 48 mmHg, respectively. Her PAP was 50 mmHg and PAOP 30 mmHg. Multifocal premature ventricular contractions were noted before and after surgery and were treated with quinidine. At autopsy, microscopic examination of her lung tissue revealed normal pulmonary arterial vessels without medial muscular hypertrophy or intimal thickening (Fig. 3). The cause of death was presumed to be from ventricular arrhythmia.

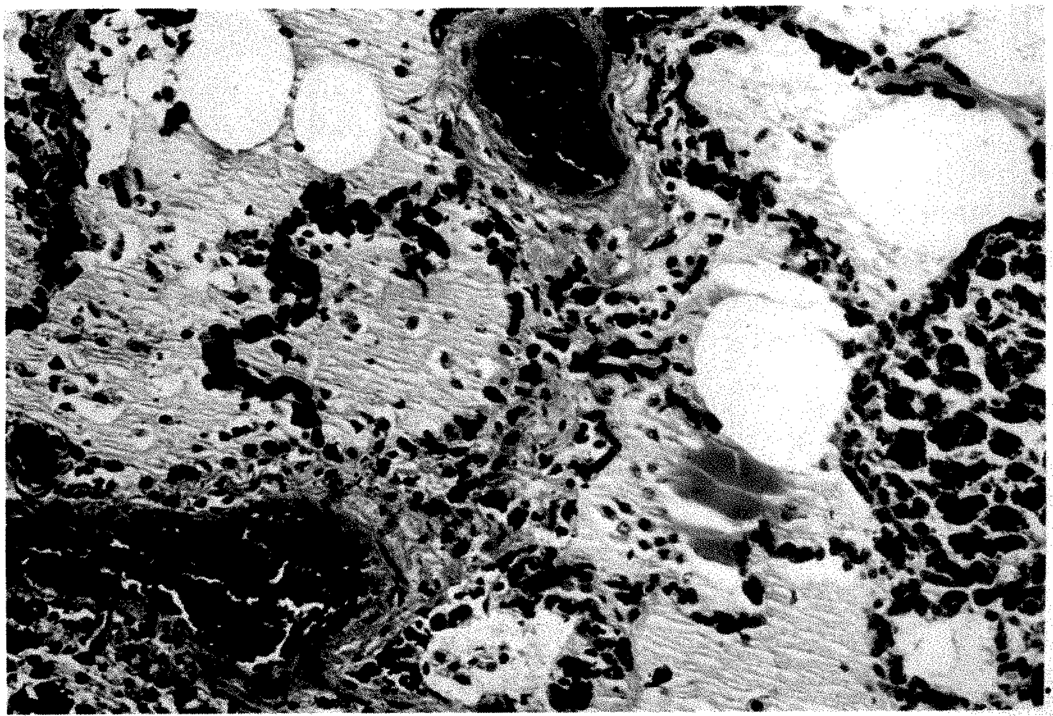

FIG. 3. Photomicrograph of lung from a 27-year-old, 472 lb patient with preoperative PaO_2 50 mmHg, $PaCO_2$ 48 mmHg, PAP 50 mmHg, PAOP 30 mmHg who died of presumed ventricular arrhythmia 5 weeks after gastric surgery. Note normal pulmonary arteries without medial muscular hypertrophy or intimal thickening (hematoxylin and eosin, original magnification ×150).

In these 18 patients, %IBW decreased from 224 ± 59 to 167 ± 57 ($p < 0.0001$), a 42 ± 19% loss of their excess weight. This weight loss was associated with significant ($p < 0.0001$) improvements in PaO_2 (from 50 ± 10 to 69 ± 14 mmHg) and $PaCO_2$ (from 52 ± 7 to 42 ± 4 mmHg) as shown in Figure 4. In this subset of the OHS group, pulmonary hypertension was present in 17 and was severe ($PAP \geq 40$ mmHg) in seven (Fig. 5). Seven of these patients had left ventricular dysfunction. The PAEDP exceeded PAOP by 5 mmHg in 13 patients. After weight loss and in association with improved arterial blood gases, PAP fell (Fig. 5) from 36 ± 14 mmHg to 23 ± 7 mmHg ($p < 0.0001$) and PAOP fell from 17 ± 7 mmHg to 12 ± 6 mmHg ($p < 0.01$). Pulmonary hypertension persisted in ten patients; however, none of them had a PAP >40 mmHg (Fig. 5). The PAOP was ≥18 mmHg in three of these patients with persistent pulmonary hypertension. There was no correlation between any measure of weight loss and postoperative PAP, PAOP, PaO_2, or $PaCO_2$. None of the 26 patients had clinical evidence of a pulmonary embolus and only the patient with the Miles® vena caval clip had lower extremity thrombophlebitis.

Of the 26 OHS patients, four with horizontal gastroplasty and three with vertical banded gastroplasty lost less than 40% of their excess weight and were subsequently converted to Roux-en-Y gastric bypass. One of these patients died on the sixth postoperative day from an occluded tracheostomy tube that had been reinserted because of recurrence of severe OHS and SAS. The remaining six patients, as well as the 19 others who underwent primary gastric bypass procedures, lost 67 ± 19% of their excess weight 1 year after gastric bypass and this weight loss has remained stable in all but two patients over a 3–6 year follow-up. The blood gas and pulmonary artery pressure data in this study were obtained after the first procedure. In three of these patients, blood gases deteriorated with weight regain and was associated with increased PAP and PAOP. These values improved again after renewed weight loss.

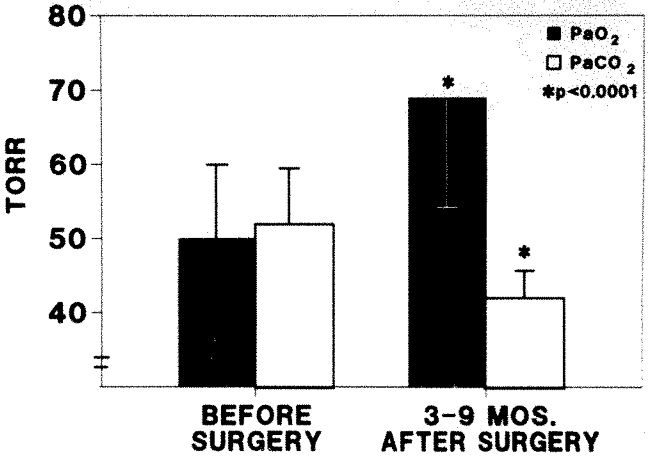

FIG. 4. Significantly improved PaO_2 and $PaCO_2$ in 18 patients 4–9 months after gastric surgery-induced loss of 42 ± 19% excess weight.

Case Reports

A 31-year-old white male taxi cab driver with a height of 74 inches weighed 590 lbs or 391 %IBW. He had been admitted on several previous occasions to the Medical Intensive Care Unit in heart failure necessitating urgent intubation and mechanical ventilation. He had severe SAS and had had several accidents as a result of falling asleep while driving his cab. Before surgery, his PaO_2 was 36 mmHg and $PaCO_2$ 57 mmHg. Following a 40-L diuresis, pulmonary artery catheterization revealed pressures of 75/34 mmHg with a PAOP of 12 mmHg. He underwent horizontal gastroplasty, tracheostomy, and insertion of a Miles® vena caval clip. He was able to be weaned from mechanical volume ventilation on the fifth postoperative day. Lower leg deep vein thrombophlebitis occurred after operation. Four months later, after losing 118 lbs, his PaO_2 had increased to 75 mmHg and $PaCO_2$ decreased to 43 mmHg. Repeat pulmonary artery catheterization revealed a pulmonary artery pressure of 40/20 mmHg with a PAOP of 10 mmHg. One year later he began to regain weight and was converted to a Roux-en-Y gastric bypass with further decrease in his weight to 240 lbs or 121 %IBW, which has been stable for 4 years. His sleep apnea is completely resolved, his PaO_2 is 85 mmHg and $PaCO_2$ is 39 mmHg. He now drives his cab without falling asleep at the wheel.

A 39-year-old black woman who is 62 inches tall and weighed 401 lbs (318 %IBW) had severe SAS with awake PaO_2 of 55 mmHg and $PaCO_2$ of 50 mmHg. Pulmonary artery catheterization revealed severe pulmonary hypertension (105/55 mmHg) and a sharply elevated PAOP (40 mmHg). Her cardiac output was 13 L/min/m^2. Before surgery an attempt was made to decrease her PAOP with furosemide; however, this was associated with a fall in cardiac output and systemic blood pressure necessitating volume restoration. She underwent tracheostomy, Roux-en-Y gastric bypass, and insertion of a Greenfield® vena caval filter. She was weaned off mechanical volume ventilation in 2 days and was discharged on the eighth postoperative day. Eight months after surgery, after losing 67 lbs (265 %IBW) her sleep apenea had completely resolved, her PaO_2 had risen to 83 mmHg; and her $PaCO_2$ had fallen to 44 mmHg. This was associated with declines in PAP to 35/29 mmHg, PAOP to 24 mmHg, and cardiac output to 8.6

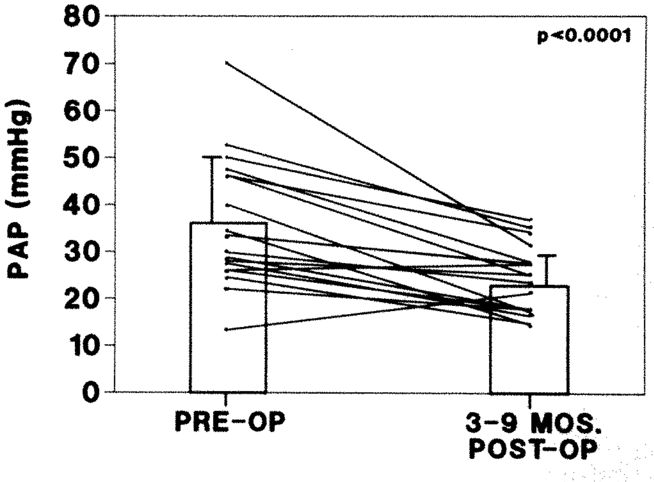

FIG. 5. Significantly improved mean pulmonary artery pressure (PAP) in 18 patients 4–9 months after gastric surgery-induced loss of 42 ± 19% excess weight.

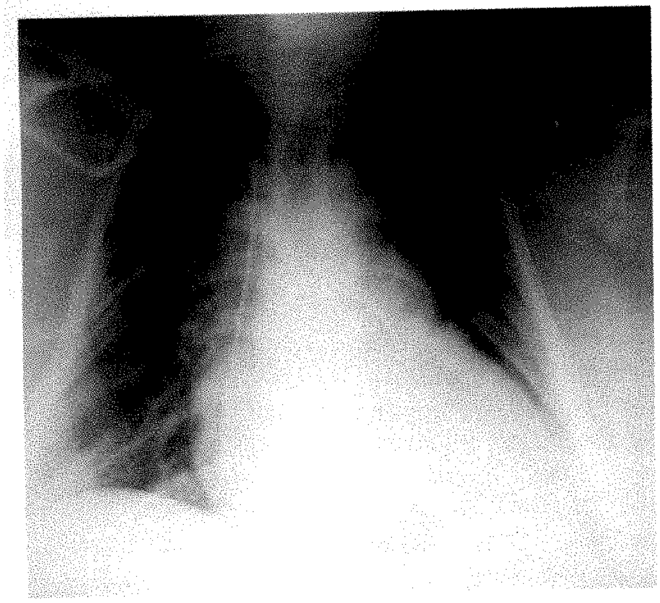

FIG. 6. Markedly enlarged cardiac silhouette on anterior-posterior portable chest roentgenogram before surgery in a 39-year-old, 62-inch tall, 401 lb black female with severe sleep apnea and awake PaO_2 55 mmHg, $PaCO_2$ 50 mmHg, PAP 105/55 mmHg, PAOP 40 mmHg, and cardiac output 13 L/min.

L/min. Her tracheostomy tube was removed and the stoma allowed to close. Three years after surgery she had lost 147 lbs (201 %IBW). At this time her PaO_2 was 95 mmHg and $PaCO_2$ was 39 mmHg. Repeat pulmonary artery catheterization revealed a PAP of 20/12 mmHg with a PAOP of 10 mmHg and 7 L/min cardiac output. A marked improvement in cardiac size can be seen by comparing her preoperative chest roentgenogram (Fig. 6) to one obtained 3 years later (Fig. 7).

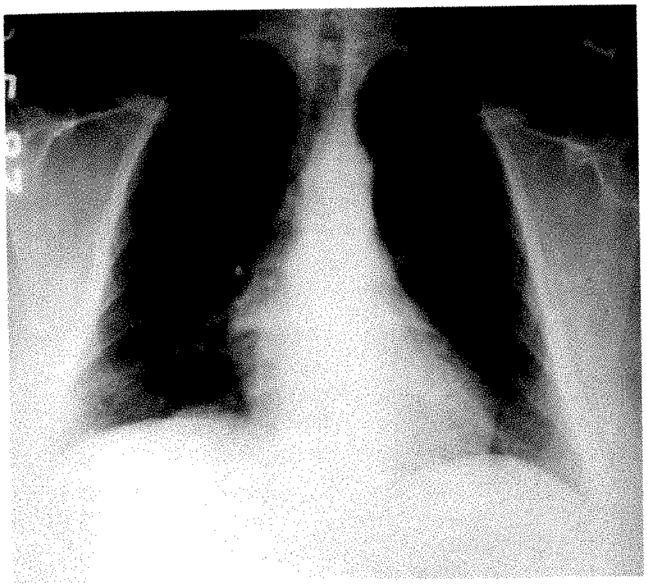

FIG. 7. Markedly improved cardiac silhouette on posterior-anterior chest roentgenogram 3 years after gastric surgery-induced 147 lb weight loss in patient from Figure 6 with correction of OHS: PaO_2 95 mmHg, $PaCO_2$ 39 mmHg, PAP 20/12 mmHg, PAOP 10 mmHg, and cardiac output 7 L/min.

Discussion

A recent consensus panel at the National Institutes of Health recognized morbid obesity as a serious medical problem in the United States,[25] affecting approximately 4.5 million persons.[26] Several studies have shown significantly increased mortality rates for the morbidly obese.[27-29] Cardiovascular disease accounts for most of this increase.[27] A subset of this population, comprising 12% of our patients who have undergone gastric surgery for morbid obesity, suffers from respiratory insufficiency of obesity, including the obstructive sleep apnea syndrome (SAS), the obesity hypoventilation syndrome (OHS), or a combination of the two.[1] Severe cardiac decompensation has been a prominent feature in many of these patients.[2-10]

This study found significant hemodynamic dysfunction in OHS patients compared with morbidly obese patients without respiratory insufficiency, including significantly higher pulmonary artery and pulmonary artery occlusion pressures. However, seven of the 20 control patients had mild pulmonary hypertension. Our initial intention was to determine the severity of presumed hypoxemic pulmonary artery vasoconstriction. Severe pulmonary hypertension was found in a large number of OHS patients; however, pulmonary hypertension appeared to be a result of both left ventricular dysfunction, as noted by an elevated PAOP, as well as pulmonary arterial vasoconstriction, where pulmonary artery end-diastolic pressures (PAEDP) were often more than 5 mmHg above the PAOP. Three patterns appeared to be present (Fig. 2): approximately one third had an elevated PAP entirely secondary to left ventricular dysfunction, since an increased PAEDP in these patients was within 5 mmHg of the PAOP; one third had pulmonary hypertension secondary to pulmonary vasoconstriction, since their PAOPs were normal; and one third had both left ventricular dysfunction (*i.e.*, PAOP $\geq$ 18 mmHg) and pulmonary vasoconstriction (*i.e.*, PAEDP > 5 mmHg above PAOP). Severe left ventricular dysfunction was seen in three patients with PAOP $\geq$ 30 mmHg in two and 40 mmHg in one. These values are consistent with a sharply decreased left ventricular compliance. Left ventricular dysfunction has been previously noted to be a significant component of heart failure in patients with OHS[5-10] and some have thought it highly unlikely that right ventricular failure could occur in these patients as an isolated event.[30]

The cause of left ventricular dysfunction in OHS could include a significant increase in central blood volume as a result of hypoxemic induced erythropoetin release. This would result in secondary polycythemia, leading to pulmonary venous and capillary congestion, and further hypoxemia. Increased central blood volumes have been found in morbidly obese patients with respiratory insufficiency[9,10] as well as in those with morbid obesity and systemic hypertension.[31] Patients with respiratory insufficiency of obesity were noted in our previous study to have a significant incidence of polycythemia that resolved with weight loss and correction of hypoxemia.[1] Although the mean hemoglobin level in the OHS patients in this study was normal, half of the patients were polycythemic, but there was no relationship between hemoglobin values and PAP or PAOP.

Other investigators have noted left ventricular dysfunction in morbidly obese patients without respiratory insufficiency.[32,33] Increased systemic arterial pressure could be responsible for left ventricular dysfunction. Marked increases in systemic arterial pressure have been noted during nocturnal hypoxemia associated with apneic episodes during sleep.[34] However, in this study, there were no significant differences in systemic arterial pressure or systemic vascular resistance index between the patients with OHS and the control group without respiratory insufficiency, suggesting that systemic hypertension was not responsible for the left ventricular dysfunction and that hypoxemia was not a significant determinant of systemic blood pressure in these patients.

Another possible mechanism for the severe left ventricular dysfunction noted in this study would be the hypoxemia itself. The heart extracts almost all of the oxygen presented to it during passage through the coronary circulation.[35] It is not surprising that these patients with extremely low PaO_2s (*i.e.,* high 30s or low 40s) might have left ventricular dysfunction. Myocardial oxygen delivery in these patients is probably made possible by increased levels of 2,3-diphosphoglycerate (2,3-DPG) with right-shifted oxygen hemoglobin equilibrium curves (increased P_{50}) and an increased ability to unload oxygen[36] as seen in high altitude[37] and patients with chronic hypoxemia.[38] We did not measure 2,3-DPG levels or P_{50} in these patients but often noted a much higher mixed venous oxygen saturation when measured with a co-oximeter than would be expected for the PvO_2 calculated from the Severinghaus nomogram.

In addition to left ventricular dysfunction, pulmonary arterial vasoconstriction contributed to pulmonary hypertension in approximately two-thirds of these patients. Hypoxemia is a known cause for pulmonary arterial vasoconstriction, which probably evolved from a need to shift pulmonary blood flow from diseased to healthy pulmonary segments. Hypoxemic vasoconstriction is an important feature of pulmonary hypertension associated with chronic obstructive pulmonary disease that can be relieved by oxygen supplementation.[39] Hypoxemic pulmonary artery vasoconstriction has also been shown to occur during nocturnal apneic episodes in patients with SAS.[34] Correction of sleep apnea in the 17 patients with both OHS and SAS in this series by weight reduction may have contributed to the improved pulmonary artery pressures as tracheostomy has been shown to improve nocturnal pulmonary hypertension by improving oxygen saturation.[34]

Our previous studies have documented a significant improvement in arterial blood gases, lung volumes, polycythemia, and sleep apnea after gastric surgery-induced weight loss.[1,12] Improvement in sleep apnea after surgically induced weight loss has also been documented by other studies.[40-42]. This study now documents an improvement in both pulmonary hypertension and left ventricular filling pressure associated with partial correction of abnormal arterial blood gases within 3–9 months after gastric surgery-induced weight loss. The absence of pulmonary arterial medial muscular hypertrophy or intimal thickening in the patient who died 5 weeks after surgery (Fig. 3) supports the reversibility of the pulmonary hypertension in these patients. In several patients who continued to lose weight, further hemodynamic improvement has been noted. Partial correction of the pulmonary hypertension and cardiac dysfunction in OHS also have been noted by others following medically induced weight loss.[43-45]

A number of patients in this study failed their gastric surgical procedure. These failures included both horizontal[15,16] and vertical banded gastroplasties.[17] Conversion to gastric bypass was associated with resumed weight loss. Gastric surgery for morbid obesity has been evolving rapidly over the past 20 years. Several procedures, especially horizontal gastroplasty[15,16] and gastric banding,[46] have been recommended in the literature but have subsequently been proven to be ineffective.[14,46] In a randomized prospective study, we found that Roux-en-Y gastric bypass was significantly more effective than the newer vertical banded gastroplasty, particularly for patients addicted to sweets.[20] In a more recent study, selective assignment of patients, *i.e.,* sweets eaters (80%) to gastric bypass and non–sweets eaters (20%) to vertical banded gastroplasty, we found that the gastric bypass patients lost, on the average, 67% of their excess weight and vertical banded gastroplasty patients lost 56% of their excess weight.[47]

Our experience confirms that surgery can be performed safely in critically ill morbidly obese patients if appropriate precautions are taken. These include preoperative pulmonary artery catheterization, careful anesthetic management, tracheostomy or nasal CPAP for patients with severe SAS, and postoperative mechanical volume ventilation with patients in a deep reverse Trendelenburg position until arterial blood gases on room air with a T-piece return to preoperative values and the patient can generate an adequate inspiratory effort and vital capacity. These patients are at great risk for fatal pulmonary embolism[11,24] and every effort must be made to minimize this risk with preoperative phlebotomy in polycythemic patients, use of intermittent venous compression boots, insertion of a Greenfield® vena caval filter in patients with severe pulmonary hypertension (PAP ≥ 40 mmHg), and early ambulation.

In conclusion, severe pulmonary hypertension is a frequent finding in morbidly obese patients with respiratory insufficiency and appears to be a result of both left ventricular dysfunction and pulmonary vasoconstriction. Gastric surgery for weight loss provides significant improvement in both the gas exchange and hemodynamic abnormalities associated with respiratory insufficiency of obesity.

Acknowledgments

The authors thank Gary Benton, M.D. for his assistance with data retrieval, Gordon E. Madge, M.D. for the pulmonary pathological evaluation and photomicrography, and the nurses, dieticians, and house staff of the Medical College of Virginia for their dedicated assistance in the management and postoperative evaluation of these challenging patients.

DISCUSSION

DR. LAZAR J. GREENFIELD (Ann Arbor, Michigan): I would like to congratulate Dr. Sugerman and his associates on their results and thank him for an opportunity to review the manuscript.

The morbidly obese patient is a social outcast, and some of that stigma in the past was conferred on surgeons who tried to rearrange the GI tract in order to help these patients lose weight. The recent change in this attitude is a result of careful clinical studies as typified by today's presentation.

Dr. Sugerman has identified a subset of these morbidly obese patients with varying degrees of pulmonary hypertension, ventricular dysfunction and hypoventilation. These disturbances were reversed by partial weight loss that left them much less obese but not normal, and this raises several questions.

First, is there a threshold of weight gain which produces these changes incrementally? That is, does the left ventricular dysfunction precede the pulmonary hypertension or does hypoxemia initiate the changes with pulmonary hypertension?

Secondly, have you characterized the left ventricular dysfunction further? Is it a global or a regional wall motion abnormality, and is fatty change of the myocardium involved?

Third, are either of the hemodynamic abnormalities treatable preoperatively, such as with the use of additional oxygen to ameliorate the pulmonary hypertension, or the use of inotropic agents or vasodilators to improve left ventricular performance?

Also, is there a change in respiratory drive in patients with elevated $PACO_2$ that would make it dangerous to reverse their hypoxemia?

Surgeons have always realized that the obese patient represents a high risk for general anesthesia and a major operative procedure, but now there is physiological proof of serious hemodynamic changes in these patients, as well as improved techniques to promote weight loss and reversal of the changes.

DR. FRANK G. MOODY (Houston, Texas): This is a disease that likely has a very strong genetic component. The animal work, for example, with well defined obese species of rats and mice clearly shows a genetic background, and in the human, it appears to be reflected in some expression of lack of ability to handle excess calories with a meal. The phenotype is probably expressed through an inability to expand excess calories through thermogenesis.

People who weighed 200, 300, 400, or 500 pounds are *supposed* to weigh that. We are trying to develop strategies to bring them down to what would be more consistent with a perceived norm in order to ensure a long and healthy life, but we are not yet sure whether we prolong life in these patients by making them thinner.

This study clearly shows that the weight itself does not appear to be the only risk factor in most of these patients. It seems to be related to other factors that lead to pulmonary dysfunction, and the biggest culprit is the cigarette.

I have performed an obesity operation on 500 patients without a mortality, and I thought that was pretty good surgery. But on reflection, 400 of these patients were operated on in Salt Lake City, primarily nonsmoking Mormons. Now, 100 have been operated on in Houston where most people seem to smoke, but with comparable results. My own clinical experience does not provide a clear answer. There was no mortality in this group either.

Out of this experience, I have five patients that had this syndrome that, until I read Dr. Sugerman's paper a couple of nights ago, I didn't know really existed. Two of these patients had a rather difficult time in the intensive care unit during the post-operative period. The knowledge derived from this paper would have allowed us to identify those people preoperatively.

I would ask Dr. Sugerman for an algorithm. Which patients should have pulmonary function studies, and which should then have invasive monitoring for postoperative care? And, in addition, would he also be a little bit more specific in terms of the role of the cigarette in his own population?

DR. JAMES PAT O'LEARY (Dallas, Texas): Obesity is a disease. When I first presented a paper dealing with this topic, a gentleman approached the podium and said, "Do you really believe that obesity is a disease?" And when I said, "Yes," he sort of huffed and went back to his seat.

I think that in this particular study we have another physiologic study that demonstrates that obese people are different.

I have a couple of comments to make. The sudden death syndrome is real, and it occurs in obese people after cholecystectomy or after surgery for morbid obesity.

Left ventricular dysfunction was present in more than half of these patients. Harvey, was there dysfunction in your control group, also? And what about the right ventricle? Was it also abnormal?

The other and final comment is: People seem to get better when they lose weight, but your patient improved after getting down to 470 lbs, whereas other patients demonstrate the disease at 300 pounds. When they lose a small amount of weight, they seem to improve, and yet when they have lost a large amount of weight, they are better. They gain back an increment, and they get rose again. So I guess I am asking: Why do they get better? Is it simply a matter of mass, or is it something else that we don't understand?

DR. RICHARD J. FIELD, JR. (Centerville, Mississippi): I have had my life endangered many times by reckless taxicab drivers. I don't think I have had the experience of having one go to sleep on me as yours did.

We, too, have been interested in obesity surgery for many years, and I think, Dr. Sugerman, this is a classic paper. I am sure that part of my opinion is a bit colored by my having had some of my training at the Medical College of Virginia, but this documentation of a fact that we already knew will be very helpful to us in obesity surgery. I haven't seen these figures before.

The Pickwickian Syndrome is something we are all familiar with, and we, too, noticed that in our series of 578, 28% of these people exhibited this strange phenomenon. It has been very gratifying to find that, as he mentioned, even where there was a small amount of weight loss, rather marked improvement was shown.

It has been our opinion that these symptoms seem to be on the basis of mass, but some other factors have come out of your study that make it interesting for us to look to the future.

The other classic part of this paper is that, for the first time, I sense a truly serious approach to the surgery of the obese has been taken.

As Dr. Greenfield mentioned, these people suffer greatly, much more, I think, than the general public and the surgical profession has understood. They truly are a diseased group, and we are now looking at them and taking obesity surgery seriously, rather than through the tongue-in-cheek approach we had taken originally.

We had a very graphic case of Pickwickian Syndrome several years ago. A man in his fifties weighed 478 pounds. He exhibited the symptoms that you discussed in your paper. Arrangements were made for his surgery. The surgery was scheduled. The week before he was to come in for his surgery, this man was found at the base of a deep crevice; he had been driving alone, and there was no other vehicle. Obviously, he had gone to sleep at the wheel.

We were too late, but thank you very much for a great bellwether for obesity surgery.

DR. HERSCHEL A. GRAVES (Nashville, Tennessee): I rise primarily to congratulate Harvey Sugerman on an excellent presentation of a good piece of work, and then to say that Frank Moody took my questions.

Harvey's work supplies data that explain the mechanics of the obesity hypoventilation syndrome. I remember that when Lynwood Herrington first began his jejunoileal bypass series 20 years ago, he performed tracheostomies on all patients. Everyone anticipated postoperative respiratory difficulties in the extreme form. It very soon became obvious that energetic routine pulmonary toilet care was sufficient and the tracheostomies weren't necessary. However, all surgeons, anesthesiologists, and their hospital staffs involved in obesity surgery still "run a bit scared" and work hard at postoperative lung care.

I have performed about 300 gastric stapling procedures and we have had no deaths and no serious pulmonary problems.

I have had only one true Pickwickian patient, and he weighed 489 pounds preoperatively. On the third postoperative day in the intensive care unit, after motioning to me for 48 hours to pull his endotracheal tube, he pulled it himself and said, "Doc, I have got to get up and walk around." So he did, and proved to us that his very poor blood gases were tolerated quite well by someone who was so accustomed to the abnormal oxygenation.

I also wonder about the tobacco. In my experience, without having a count, very few morbidly obese patients smoke. I wonder if one of your statisticians could go back and determine if the patients with poor arterial gases are smokers. I think that might be an interesting added factor in this analysis.

This is an excellent piece of work, Harvey.

DR. HARVEY SUGERMAN (Closing discussion): I would like to thank all the discussants, but I would particularly like to thank Dr. Greenfield for his support. When he was at the Medical College of Virginia, I proposed to him my interest in pursuing surgery on these patients. He said, "By all means, go ahead, but make sure you study what you are doing." This was excellent advice for a new faculty member and was very helpful to me.

There were several questions with regards to the threshold weight. Certainly a number of these patients will improve markedly with a very small amount of weight loss. However, without performing heart catheterization monthly, it was not possible in this study to determine the threshold weight. A few patients improved significantly but did not return to normal by the time of restudy, although they corrected the abnormal pulmonary gas exchange and hemodynamic dysfunction completely over several years. Pulmonary hypertension did not correct in the early postoperative period with mechanical ventilation and correction of the hypoxemia, so there is more than just pulmonary hypoxemic vasoconstruction going on. One patient died suddenly five weeks after surgery. This lady had had multifocal PVC's prior to surgery and was on quinidine. Surprisingly, her pulmonary arterioles were normal at autopsy, since I had predicted pulmonary arterial intimal hyperplasia.

It is very difficult to determine if the cause of cardiac dysfunction is secondary to problems with the left ventricle, the right ventricle, or both. Increased systemic afterload is one possibility. Patients with obstructive sleep apnea will have systemic hypertension during their obstructive episodes and hypoxemia. The PA and wedge pressures have also been found to go up as their systemic pressure rises. However, our patients had no difference in systemic pressure compared to the morbidly obese controls, so increased afterload was not the cause of left ventricular dysfunction in our patients.

Polycythemia and increased central blood volumes have also been incriminated, but there was no correlation in this study between hemoglobin and pulmonary artery pressure. Perhaps it is a problem with an increased pulmonary afterload, dilatation of the right ventricle, and shift of the interventricular septum to the left, with a decreased left ventricular end diastolic volume. Some of these patients had PaO_2's in the high 30's and low 40's. Since the heart extracts all the oxygen that it gets, the heart may not be getting enough oxygen and develops a stiff, poorly compliant myocardium that takes weeks or months to repair. We have no data regarding whether hypoxemia precedes or is subsequent to left ventricular dysfunction, but I presume it is the former. In the future, we plan to obtain MUGA scans of both the right and left ventricles pre- and postweight reduction surgery.

In response to Dr. O'Leary's questions, mild left ventricular dysfunction was also noted in our morbidly obese control group without respiratory insufficiency. We have also found that ventricular function improved in this group following surgically induced weight loss. Sudden death syndrome has been seen in four of our more than 700 morbidly obese patients following obesity surgery: one at 3 days without known pre-existing heart disease; one at 5 weeks in the patient described in our report who had pre-existing arrhythmias and respiratory insufficiency; one at 5 months in a patient with idiopathic hypertrophic subaortic stenosis, and one at 1 year in a patient with muscular dystrophy who required a pacemaker for complete heart block prior to obesity surgery. Postmortem examinations were performed in three of these patients and did not reveal a cause of death. A prolonged QT interval seen in morbidly obese patients and associated with sudden death was not noted in any of these patients.

We have not studied the use of inotropic or vasodilator agents in these patients. We have tried to diurese them and remove presumed excess intravascular volume. This was tried in the patient with the wedge pressure of 40. However, diuresis was associated with a decreased cardiac output and required volume re-expansion. This patient probably had a stiff, poorly compliant ventricle and needed a high wedge pressure to maintain adequate left ventricular end diastolic volume and cardiac output.

Giving supplemental oxygen did not diminish respiratory drive, and several were treated with nocturnal oxygen.

I certainly agree with both Dr. Moody and Dr. Graves that most of these patients had an additional pulmonary problem. 80% of these patients were smokers, in contrast to 10% of the morbidly obese control group. So, as far as the lungs are concerned, it may be all right to be morbidly obese, and it is certainly not all right to smoke, but when one does both, then there is a real problem. A second pulmonary problem on the top of obesity tips the scale.

With regard to management algorithms, pulmonary function tests have been interesting, but have not been very helpful as a routine preoperative evaluation. I think all morbidly obese patients should have a preoperative arterial blood gas determination. A history of having fallen asleep at the wheel, heavy snoring, waking up with headaches, very restless sleep, or multiple awakenings strongly suggest obstructive sleep apnea syndrome. These patients should undergo preoperative sleep polysomnography. Trauma surgeons must be alert to the patient who is injured in an automobile accident and is suspected of having fallen asleep at the wheel. We used to perform a tracheostomy on all patients with severe obstructive sleep apnea. But we treat them now with nocturnal nasal CPAP, which is a mask that fits over the nose and corrects the obstructive episodes. If they won't tolerate nasal CPAP and they have severe sleep apnea with cardiac arrhythmias, they need a tracheostomy. If the patient has hypoxemia and/or hypercarbia when awake, the patient should undergo right heart catheterization. If their mean pulmonary artery pressure is very high, that is, >40 mmHg, a Greenfield filter should probably be inserted.

Anesthesia in these patients is potentially very dangerous. However, we have not had a life-threatening anesthetic event in any of our morbidly obese patients, including those with respiratory insufficiency. We usually have three anesthetic personnel available: one to hold the mask, one to squeeze the bag, and one to help administer medications. Awake intubation is usually very traumatic and, in our experience, unnecessary.

Postoperatively, these patients should be kept in the reverse Trendelenburg position to maximize diaphragmatic excursion. Venous compression boots are used to counteract the increased venous pressure and reduce the risk of thromboembolism. A volume ventilator is used until the patient's blood gases return to their preoperative hypoxic, hypercarbic state. If you wait until they completely correct their hypoxia, you will have a long wait. But eventually these problems will be resolved, with the weight loss making the surgery truly lifesaving in this high risk group of patients.

Resection of Hepatic Duct Bifurcation and Transhepatic Stenting for Sclerosing Cholangitis

JOHN L. CAMERON, M.D.,* HENRY A. PITT, M.D.,* MICHAEL J. ZINNER, M.D.,* H. FRANKLIN HERLONG, M.D.,† STEPHEN L. KAUFMAN, M.D.,‡ JOHN K. BOITNOTT, M.D.,§ and JOANN COLEMAN, R.N., M.S.*

Thirty-one patients with sclerosing cholangitis underwent reconstruction of their hepatic duct bifurcation and long-term stenting between 1980 and 1987. Indications for surgery were persistent jaundice in 29 and recurrent cholangitis in two. The mean serum bilirubin level before surgery was 10.4 mg/dl. Liver biopsy revealed that 26 patients had varying degrees of hepatic fibrosis, and five patients had progressed to secondary biliary cirrhosis. In 29 patients the major obstructive duct disease was at or near the hepatic duct bifurcation, and in two patients it was in the distal common duct. The operative procedure consisted of: (1) excision of the hepatic duct bifurcation and extrahepatic biliary tree, (2) dilatation of the intrahepatic ducts, (3) insertion of Silastic transhepatic biliary stents, and (4) bilateral hepaticojejunostomies. Two of the five patients (40%) with cirrhosis died after surgery. In contrast, only one of 26 patients (3.9%) with hepatic fibrosis died after operation. The 1-, 3-, and 5-year actuarial survival rates for patients with cirrhosis were 20%, 20%, and 20%, respectively. The only long-term survivor underwent a liver transplant. The 1-, 3-, and 5-year actuarial survival rates for patients with hepatic fibrosis were 92%, 87%, and 71%, respectively. In addition, the mean serum bilirubin levels of patients with hepatic fibrosis at 1, 2, 3, 4, and 5 years were 3.4 mg/dl, 2.9 mg/dl, 4.0 mg/dl, 5.4 mg/dl, and 4.3 mg/dl, respectively. Two of the long-term survivors subsequently underwent a liver transplant. Patients with sclerosing cholangitis, persistent jaundice, and biliary cirrhosis should be referred for consideration of liver transplantation. However, in the absence of biliary cirrhosis, if the major obstructive disease is at the hepatic duct bifurcation, primary biliary reconstruction and long-term stenting should be considered.

SCLEROSING CHOLANGITIS is an idiopathic disease presenting with multiple inflammatory strictures of the biliary tree, usually involving both the intra- and extrahepatic bile ducts, and often most severe at the hepatic duct bifurcation.[1] The disease generally presents with jaundice and pruritis. Despite its name, episodes of fever usually occur only after operation or nonoperative biliary intervention. The disease is seen most commonly in middle-aged males, often with associated inflammatory bowel disease.[2-4] The clinical course of sclerosing cholangitis is usually episodic, and quite variable. However, in most series the disease has generally been progressive, eventually leading to secondary biliary cirrhosis and hepatic failure. A variety of treatment regimens ranging from anti-inflammatory and immunosuppressive drugs to liver transplantation have been tried. In 1983, in a small series of patients, we reported a surgical approach consisting of excision of the hepatic duct bifurcation and extrahepatic biliary tree, dilatation of the intrahepatic ducts, and long-term stenting with Silastic transhepatic stents.[5] We have continued to treat patients with sclerosing cholangitis with this same regimen, and herein report our experience with a total of 31 patients.

From The Departments of Surgery, Medicine,† Radiology,‡ and Pathology,§ The Johns Hopkins Medical Institutions, Baltimore, Maryland*

Clinical Material

Between 1980 and 1987, 31 patients with sclerosing cholangitis underwent primary biliary reconstruction. These 31 patients were selected from a group of approximately 100 patients with sclerosing cholangitis seen at Johns Hopkins during this interval. Ninteen patients were men, 12 were women, and the mean age was 44.7 years (range: 21–71 years). Twenty-seven of the patients were white and four were black. The diagnosis of sclerosing cholangitis was made in all patients on the basis of multiple preoperative precutaneous and endoscopic ret-

TABLE 1. *Sclerosing Cholangitis (N = 32)*

Admission Laboratory Data	
Bilirubin (NL 0.3–1.2 mg/dl)	10.4 mg/dl (1.0–50.0 mg/dl)
Alkaline phosphatase (NL 30–120 IU/L)	528 IU/L (144–1860 IU/L)
SGOT (NL 0–35 IU/L)	146 IU/L (35–413 IU/L)
SGPT (NL 0–30 IU/L)	171 IU/L (39–696 IU/L)

rograde cholangiograms. In addition, numerous cholangiograms obtained at prior surgical procedures were reviewed. In all instances, multiple biliary strictures were present, involving both the intra- and extrahepatic biliary tree. In no patient could operative injury or biliary calculus disease be considered a major factor in the genesis of the inflammatory strictures. In addition, cholangiocarcinoma was subsequently ruled out in all patients because the entire extrahepatic biliary tree was excised and examined histologically in each instance. Two patients with sclerosing cholangitis who underwent biliary reconstruction were excluded from this series, when at the time of surgery they were found to have an associated proximal biliary tumor.

Disease duration was often difficult to determine. However, it was estimated to have ranged between 1 month and 13 years, with a mean duration of 3 years. Fourteen of the 31 patients had biopsy-proven inflammatory bowel disease, and eight of these patients had undergone bowel resection. Ten of the 14 patients with inflammatory bowel disease had ulcerative colitis, and four had Crohn's disease. Four of the patients (one with Crohn's disease, three with ulcerative colitis) had ileostomies at the time of biliary reconstruction for their sclerosing cholangitis. One patient with ulcerative colitis had had a colectomy for carcinoma. Four patients with sclerosing cholangitis had chronic pancreatitis, as evidenced by a clinical history of multiple episodes of abdominal pain and hyperamylasemia, and confirmed by gross findings at the time of surgery for sclerosing cholangitis.

TABLE 2. *Sclerosing Cholangitis (N = 31)*

	No. of Patients
Indications for surgery	
Persistent jaundice	29
With cholangitis	11
Recurrent cholangitis	2
Area of major duct involvement	
Bifurcation	29
Distal common duct	2

Nineteen of the 31 patients had undergone prior biliary tract surgery at other institutions. These procedures included cholecystectomy, insertion of a T tube, choledochoduodenostomy, and choledochojejunostomy. Nine of the 31 patients had undergone intra-abdominal procedures for other than biliary tract disease, in most instances bowel resections for inflammatory bowel disease. Many patients had been treated medically for sclerosing cholangitis before referral to The Johns Hopkins Hospital. In most instances the drug was a steroid (12 patients), or azathioprine (6 patients), but a variety of other medications including cholestyramine and D-penicillamine had been used.

At the time of admission for biliary reconstruction, the serum bilirubin level among these 31 patients ranged from a low of 1.0 mg/dl to a high of 50 mg/dl. The mean bilirubin level at the time of admission was 10.4 mg/dl. Alkaline phosphatase level ranged from a low of 144 IU/L to a high of 1860 IU/L, and averaged 528 IU/L. The SGOT ranged from a low of 35 IU/L to a high of 413 IU/L and averaged 146 IU/L. The SGPT ranged from a low of 39 IU/L to a high of 696 and averaged 171 IU/L (Table 1). Liver biopsies were obtained from all patients either before operation or at the time of surgery. Twenty-six patients had varying degrees of fibrosis, but five patients had clearly progressed to secondary biliary cirrhosis.

The indication for surgical intervention in 29 patients was persistent jaundice (Table 2). This was defined as a bilirubin level of 5 mg/dl or greater persisting for at least a 3-month period. Eleven of these 29 patients, all of whom had had prior biliary tract surgery, also had recurrent bouts of cholangitis. Two patients, in the absence of persistent jaundice, had recurrent bouts of cholangitis as their indication for surgical intervention. All patients had intra- and extrahepatic biliary duct involvement, and in 29 patients the bifurcation was severely involved (Fig. 1). In the remaining two patients the area of most severe involvement was the distal common duct.

Before surgery, 19 of the 31 patients at the time of percutaneous transhepatic cholangiography had Ring catheters inserted into the intrahepatic biliary tree, and passed down through the areas of stricturing into the duodenum (Fig. 2). In eight of the 19 patients only one Ring catheter was inserted, generally into the right hepatic duct, but in 11 patients both the right and left intrahepatic ducts were cannulated percutaneously. Ring catheters were inserted before operation in only five of the first 15 patients operated on before 1983 for sclerosing cholangitis. However, 14 of the last 16 patients, operated on since 1983, have had catheters inserted, and in nine of the 14 patients the catheters were placed bilaterally. These catheters were placed before operation not to decompress the obstructed biliary tree, but to (1) aid in the dissection of the hepatic duct bifurcation at the time of surgery; (2) to assist in dilating the intrahepatic ducts at the time of surgery; and (3) to aid in the placement of the Silastic transhepatic biliary stents.

Operative Procedure

Patients were explored through a right subcostal incision. The extrahepatic biliary tree was identified, and if the gallbladder had not previously been removed, a cholecystectomy was performed. The common duct was dissected free and encircled with a vessel loop. Often because of prior surgery as well as inflammatory changes in the duct, identification of the extrahepatic biliary tree would have been difficult if a Ring catheter had not been placed before operation. As soon as the common duct was encircled, it was dissected distally to where it passed posterior to the duodenum. At this point the distal common duct was divided, the Ring catheters extracted from the duodenum, and the distal common duct oversewn. The proximal biliary segment, with the Ring catheters acting as a guide, was then carefully dissected up to the hepatic duct bifurcation. The hepatic duct bifurcation was easily identified by palpatating the divergence of the two Ring catheters. The bifurcation was dissected both anteriorly and posteriorly by reflecting the proximal biliary segment in a cephalad direction. The Ring catheters aid greatly in retracting the proximal biliary segment, as well as in identifying and dissecting out the right and left hepatic ducts. When the bifurcation has been dissected, the right and left hepatic ducts are divided and the extrahepatic biliary tree removed from the operative field.

As described in our last communication, if Ring catheters are not present, the right and left hepatic ducts are carefully and tediously dilated with the use of Bake's dilators.[5] This maneuver has to be performed carefully because if a false passage is made, and the Bake's dilator passes through the wall of the intrahepatic ductal system, further dilatation up into the intrahepatic biliary tree is impossible. With Ring catheters in place, this dilatation can be performed rapidly, safely, and without the risk of a false passage. Dilatation is performed by suturing progressively larger Coude catheters to the Ring catheter, and withdrawing the Ring catheter out the top of the liver, thereby progressively drawing larger catheters up through the intrahepatic biliary tree, and thus dilating it. Generally a #12 F Coude catheter is sutured to the Ring catheter and pulled up into the intrahepatic biliary tree first. A #14 F Coude catheter is then sutured to the #12 F catheter and used to further dilate the biliary tree. This is followed by pulling up a #16 F Coude catheter, and then finally the #18 F Silastic transhepatic biliary stent. These maneuvers are performed over a guidewire, so that if a catheter breaks or becomes unsutured, the tract is not lost. This progressive catheter dilatation has made what in the past has been a relatively

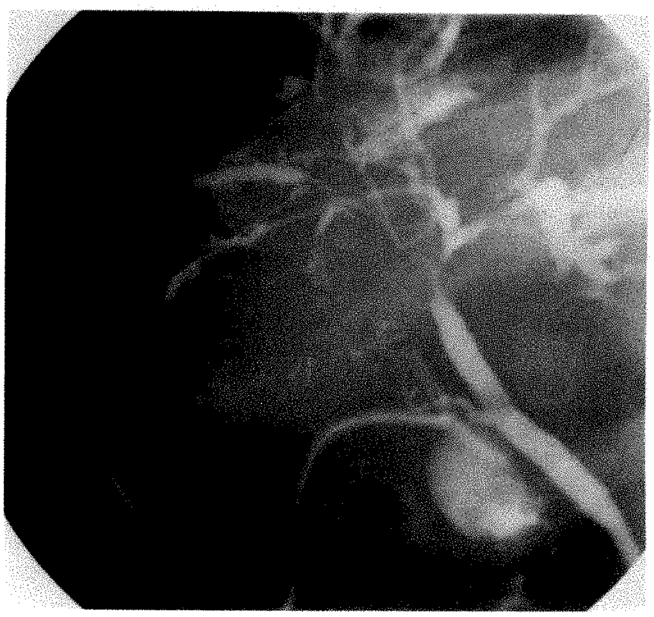

FIG. 1. Percutaneous transhepatic cholangiogram of a patient with sclerosing cholangitis and with persistent jaundice, with the most severe disease being at the hepatic duct bifurcation. Note that the T tube, inserted at another institution, has been displaced.

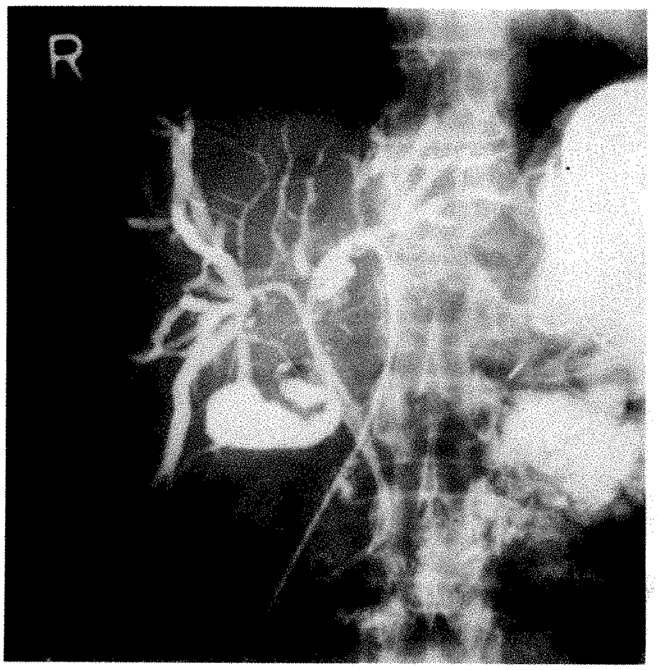

FIG. 2. A patient with sclerosing cholangitis, persistent jaundice, and severe bifurcation involvement. Ring catheters have been inserted percutaneously before operation, to serve as technical aids at the time of surgery.

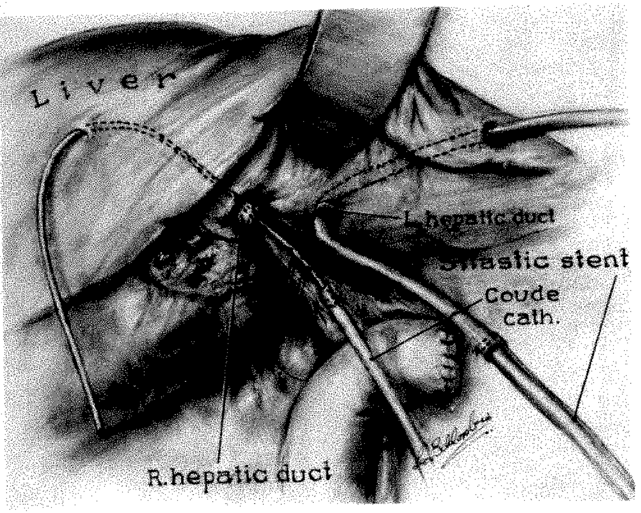

FIG. 3. Progressively larger Coude catheters are sutured, first to the Ring catheter, and then to each other,, and are drawn up through the biliary tree, thereby dilating it. Finally, a Silastic transhepatic biliary stent is sutured to the last Coude catheter, and is drawn into place.

unsafe and uncertain dilatation, into a safe and certain way to ensure dilatation of the intrahepatic ducts (Fig. 3).

Silastic transhepatic biliary stents were placed in 30 of the 31 patients. In one of the two patients with only a distal biliary stricture, a T-tube was used. In six patients only one stent was inserted, generally because one lobe was atrophic and not believed to be worth decompressing or because the biliary tree was so strictured in one lobe that it could not be intubated. In 19 patients, bilateral transhepatic biliary stents were inserted, and in five patients three stents were used. In the five patients in whom three stents were inserted, two stents were placed on the right side, one in each major segment. A Roux-en-Y jejunal loop 60 cm in length was then constructed. The Roux-en-Y loop was brought up into the right upper quadrant in a retrocolic position. One, two, or three hepaticojejunostomies were then performed, depending on how many major lobar or segmental hepatic ducts had been intubated with Silastic transhepatic biliary stents. The Silastic stents extended into the Roux-en-Y loop for approximately 10–15 cm. That portion of the Silastic stent that resided in the Roux-en-Y loop and in the intrahepatic ductal system, contained multiple side holes. That portion of the Silastic stent that exited through the diaphragmatic surface of the liver was brought out through a stab would either in the right or left upper quadrant. The stents were sutured securely to the skin with two stainless steel wires. The hepaticojejunostomies and stent exit sites were drained with drains brought out through stab wounds in the upper abdomen.

Clinical Course

In all 31 instances the resected specimens revealed benign inflammatory disease. Three patients died after operation, for a hospital mortality rate of 9.7%. Two of these three patients were among the five patients who had established biliary cirrhosis (hospital mortality rate of 40%). Among the remaining 26 patients with varying degrees of hepatic fibrosis, there was only one death for a hospital mortality rate of 3.9%. The three patients died 31, 37, and 60 days after surgery of liver failure and sepsis. Two of the patients who died developed hematobilia after operation, secondary to an hepatic artery portal venous fistula that required control *via* percutaneous embolization. This occlusion of hepatic arterial inflow to the liver may have further hastened their development of liver failure.

The convalescences of the 28 patients who were discharged from the hospital were prolonged but relatively uneventful. Three of the patients had continued episodes of cholangitis that required prolonged antibiotic administration to control. One patient developed a subhepatic collection after surgery that was drained percutaneously. A final patient with an unrecognized cardiomyopathy required treatment for pulmonary edema after operation. The average hospital stay of the 28 patients who were discharged from the hospital was 28 days. However, over the past 3 years during which an effort has been made to shorten the hospitalization of all surgical patients, the last seven patients have been operated on and discharged with an average length of stay of 15 days.

Among the three patients with biliary cirrhosis who were discharged from the hospital, two died of liver failure, 6 and 8 months after discharge. The only patient among the five patients with biliary cirrhosis who survived long term underwent liver transplantation 2.5 years after his reconstructive biliary surgery. He continues to lead an active life after liver transplantation 80 months after his initial biliary tract reconstruction.

The 25 patients without biliary cirrhosis who were discharged from the hospital have fared much better. The mean serum bilirubin level of this group of patients before surgery was 9.9 mg/dl. At 12 months after surgery the mean serum bilirubin level was 3.4 mg/dl, at 24 months 2.9 mg/dl, at 36 months 4.0 mg/dl, at 48 months 5.4 mg/dl, and at 60 months 4.3 mg/dl (Fig. 4). The changes in alkaline phosphatase and serum transaminase levels were less impressive (Fig. 5). Two of these 25 patients subsequently underwent successful liver transplantation, 48 and 80 months after biliary reconstruction, because of progressive liver disease. One patient is alive and well 93 months after her initial reconstruction. The second patient died of chronic rejection 1.5 years after her transplant. There have been six additional deaths among these 26 noncirrhotic patients. Five of the deaths have been from chronic liver failure, and the sixth was from metastatic lung cancer.

The Silastic biliary stents have been left in permanently to prevent restricturing within the major intrahepatic ducts (Fig. 6). The stents are changed over guidewires as an outpatient procedure every 3 months. An occasional patient because of excessive sludge formation will require stent changes as often as every 6 to 8 weeks. Episodes of fever have been unusual, and generally signify that a stent change is needed.

Mean follow-up for the entire group is 3.5 years. The mean survival for all 31 patients is 42 months, with a median survival of 44 months. Actuarial survival rates at 1, 3, and 5 years are 80%, 76%, and 63%, respectively. Among the five cirrhotic patients, mean survival is 19 months with median survival of 6 months. Actuarial 1-, 3-, and 5-year survival rates are all 20%. Among the 26 patients without cirrhosis, mean survival was 46 months, with median survival being 48 months. Actuarial 1-, 3-, and 5-year survival rates are 92%, 87%, and 71%, respectively (Fig. 7).

Discussion

Because sclerosing cholangitis is episodic in nature, has an extremely variable course, and is an uncommon disease, natural history data are difficult to obtain. The best data suggest that the disease proceeds slowly and inevitably to the point where in many patients biliary cirrhosis will develop and hepatic failure ensue.[2,3] One recent study, however, suggests that this scenario may not be as inevitable as previously believed.[6] All of these uncertainties make therapeutic interventions particularly difficult to evaluate. Steroids have been the mainstay of treatment for this disease almost from the time it was described. However, no data from any institution have established their efficacy in a broad group of patients. Other drugs such as azathioprine, D-penicillamine, and colchicine have been used, but again no convincing data support their benefit.

In several institutions, including our own, percutaneous intubation of the biliary tree and balloon dilatation

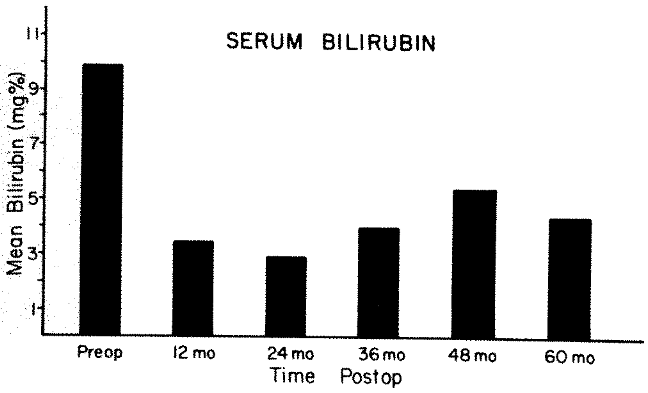

FIG. 4. Serum bilirubin levels before and after surgery for the 26 patients with hepatic fibrosis (before operation N = 26, 12 months N = 21, 24 months N = 20, 36 months N = 18, 48 months N = 13, 60 months N = 12).

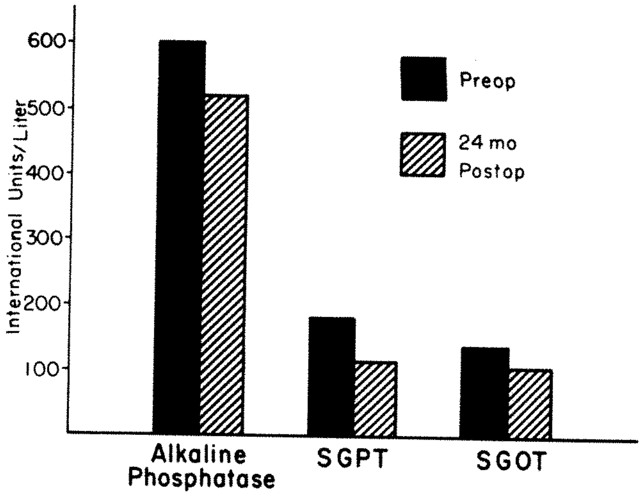

FIG. 5. Serum alkaline phosphatase, SGPT, and SGOT levels before and after surgery for the 26 patients with hepatic fibrosis (before operation N = 26, 24 months N = 20).

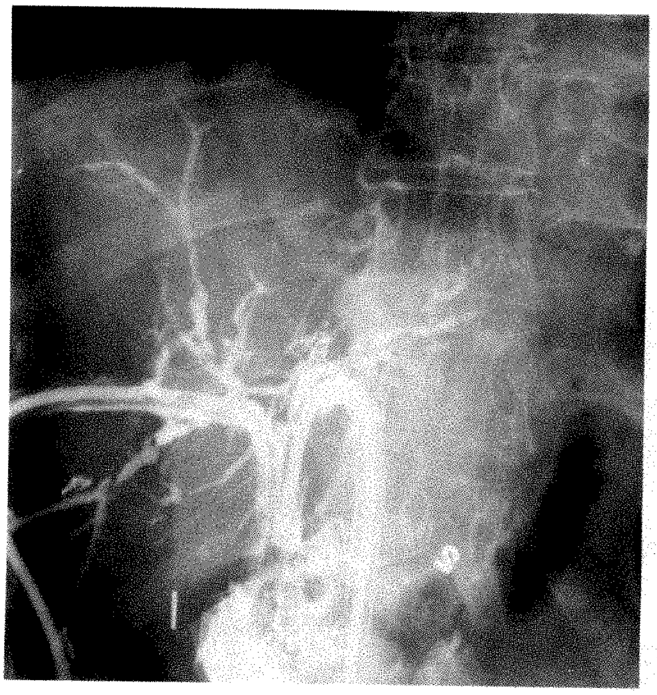

FIG. 6. Postoperative cholangiogram after bifurcation reconstruction demonstrating the biliary drainage achieveable with this procedure.

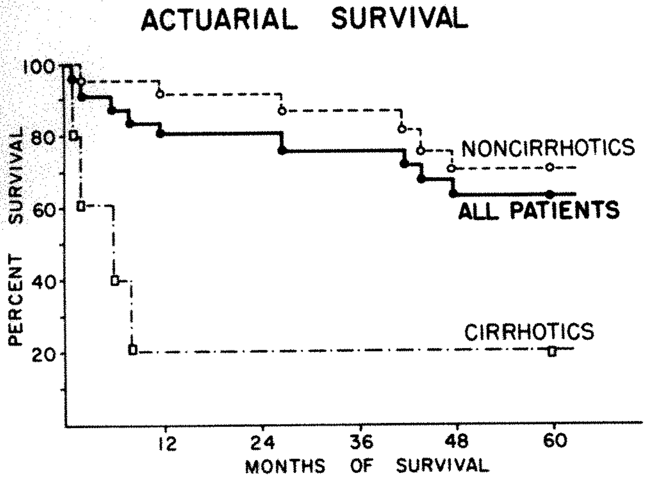

FIG. 7. Actuarial 5-year survival curves for the 31 patients with sclerosing cholangitis undergoing reconstruction of the hepatic duct bifurcations (all patients N = 31, noncirrhotics N = 26, cirrhotics N = 5).

have been used for iatrogenic strictures.[7] This technique has recently been extended to patients with sclerosing cholangitis. However, the strictures in sclerosing cholangitis often do not lend themselves to this approach. The biliary tree with its multiple fibrotic branches can be difficult to intubate either percutaneously or endoscopically. Moreover, multiple procedures and, sometimes, general anesthesia are required with balloon dilatation. Thus, in our experience, this course of therapy has frequently been unsuccessful and/or not well tolerated. Others have suggested operatively resecting the distal biliary tree and performing a hepatico- or choledochojejunostomy to a Roux-en-Y loop. The end of the Roux-en-Y loop is then brought out as a cutaneous or subcutaneous stoma to provide access for postoperative catheter balloon dilatation of intrahepatic strictures. In one report of 16 patients managed with this approach, results have been moderately encouraging in noncirrhotic patients.[8]

The recognition and documentation that the strictures in sclerosing cholangitis are often most severe in the area of the bifurcation, as reported from this institution,[1] has led to a new surgical approach reported first in 11 patients in 1983.[5] Although others had recognized in the past that severe stricturing often occurred at or near the hepatic duct bifurcation, its functional significance had not been recognized because of the failure of the fibrotic intrahepatic biliary tree to dilate. In 1983, we suggested that these bifurcation strictures were functionally significant, and that the disease might be treated effectively by resecting the hepatic duct bifurcation, dilating the intrahepatic biliary tree, and permanently stenting the ductal system with Silastic transhepatic biliary stents. Because it was believed that the stricturing would recur if the Silastic stents were removed, our approach was to leave them in permanently. Among the 11 patients initially reported, one patient died after operation without leaving the hospital. Among the remaining 10, seven are still alive. Three patients eventually required hepatic transplantation because of progressive liver disease, and two of these three remain among the seven still surviving. Mean follow-up of this group of 11 patients now extends to 64 months.

Hepatic transplantation remains another option for the management of patients with sclerosing cholangitis. A large experience has been obtained in Pittsburgh, and sclerosing cholangitis is now the third most common indication for liver transplantation in adults at that institution.[9] Transplantation is a big operative procedure that requires chronic immunosuppression. However, at a certain stage of the disease it remains the only and an excellent option. Nevertheless, the risks of hepatic transplantation are still such that if it can be avoided, or put off, and other alternatives made available, many believe that would be a preferable option.

A recent report from the University of Pittsburgh documents that 1- and 3-year survival rates are 71% and 57%, respectively, among 55 patients undergoing liver transplantation for sclerosing cholangitis.[9] In the current series of 31 patients undergoing resection of the hepatic duct bifurcation and transhepatic stenting, 1- and 3-year survival rates are 80% and 76%, respectively. However, in the 26 noncirrhotic patients, survival rates are 92% and 87% at 1 and 3 years, respectively. This group of noncirrhotic patients may not be directly comparable to patients with established cirrhosis who undergo liver transplantation. However, the results obtained in these noncirrhotic patients may suggest that our surgical approach is warranted in this subset of patients.

Our operation is only palliative and will be of benefit only if large duct obstruction plays a significant role in the progressive liver disease that patients with sclerosing cholangitis experience. In our series three patients required liver transplantation because of progressive liver failure. The transplants were successful in all three patients. Moreover, in the University of Pittsburgh series prior biliary tract surgery did not adversely influence long-term survival.[10] Thus, if our approach is not successful, hepatic transplantation remains a viable option.

The current series of patients suggests that the option of excising the hepatic duct bifurcation in the face of persistent hyperbilirubinemia and major stricturing in this area, along with dilatation of the intrahepatic biliary tree and permanent stenting, is an alternative that has a great deal of appeal. If one excludes patients who before operation are demonstrated by needle biopsy to have cirrhosis, the operative procedure can be done with a very low hospital mortality. Furthermore, with the use of Ring catheters placed percutaneously before operation, the hepatic duct bifurcation can be identified, dissected, and readily excised. In addition, with the Ring catheters in place, the operative dilatation of the intrahepatic biliary tree can be quickly and safely accomplished. Finally, by the long-term use of operatively placed Silastic transhepatic biliary stents, restricturing can be avoided. The demonstration that this operative procedure can result in a marked and persistent lowering in serum bilirubin, and an excellent 5-year actuarial survival, speaks in favor of this approach.

Our current approach is to follow patients with sclerosing cholangitis without specific therapy as long as persistent hyperbilirubinemia does not develop. When persistent hyperbilirubinemia develops, as defined by a serum bilirubin level of 5 mg/dl or greater for at least 3-months, percutaneous liver biopsy should be performed. If there is any question about the right lobe being atrophic, then the left, or perhaps both lobes, should be biopsied. If biliary cirrhosis is present, the patient should be referred for consideration of hepatic transplantation. If biliary cirrhosis is not present, and cholangiography demonstrates severe stricturing at or near the hepatic bifurcation, or in the distal biliary tree, we believe that primary biliary reconstruction should be considered. The approach of excising the hepatic duct bifurcation and the extrahepatic biliary tree, dilatation of the intrahepatic biliary tree, and long-term stenting can provide such a patient with good quality long-term survival. If the patient does not respond to this primary procedure, or subsequently the liver disease progresses and jaundice recurs and/or biliary cirrhosis develops, liver transplantation can still be performed. We believe such an approach does not preclude, but may well postpone, or even avoid in some instances, the need for liver transplantation.

DISCUSSION

DR. RONALD K. TOMPKINS (Los Angeles, California): Dr. Cameron and his group have done their usual fine job in presenting the results of a successful treatment of a very difficult disease.

We at UCLA have had similar experiences with this disease in the past, and we agree with their thesis that operative therapy in the proper patient is far superior to medical therapy for sclerosing cholangitis.

I do have some questions that I hope that the group will address in their closing remarks.

First, in reviewing the manuscript last evening, I noticed that there were 100 patients at Hopkins during this period of time with the diagnosing of sclerosing cholangitis. Of these, only 31 were selected for operation, and I wonder if the authors would tell us what their specific selection criteria are. I think that would be very helpful to us.

Secondly, it has been difficult for us to determine at what time after the onset of obstruction of the biliary tract that secondary biliary cirrhosis develops. I wonder if the authors could give us some clues as to the time frame for the development of biliary cirrhosis.

Thirdly, amongst radiologists, there is an interest now for percutaneous dilatation of these strictures and for nonoperative treatment of this disease, and I wonder what the experience has been at Hopkins with this method and whether they are considering this as an alternative in the management of these patients.

I think Dr. Cameron mentioned that these transhepatic stents stay in permanently, and I wonder if he could tell us what the incidence of cholangitis and septic complications is with those permanent in-dwelling tubes.

Finally, I would agree with the authors that the patient who is clearly defined as cirrhotic at the outset of the evaluation should be referred directly for a liver transplantation.

Liver transplantation is often a difficult operation in itself, and when there has been previous biliary tract surgery done, it makes the transplant much more difficult and increases the operative morbidity and mortality risk.

I enjoyed the presentation of this very nice paper, and I appreciate the authors' giving me the opportunity to review the manuscript.

DR. KENNETH W. WARREN (Boston, Massachusetts): About two years ago I promised myself that I would never discuss another paper on this subject.

Having recently written another chapter, and standing here today to discuss this paper, just shows that my word is not reliable, especially when I make a vow to myself.

Over the years, I have had a considerable experience with this disease. It is a disease of unknown etiology, despite its frequent association with inflammatory bowel disease.

It has no distinctive pathologic features. There is no satisfactory medical treatment. Initially, we who had been treating this disease for 30 or 40 years were rather tentative in our surgical approach. I think what Dr. Cameron and his group have shown here today indicates that an aggressive approach to a special type of sclerosing cholangitis, where the major lesion is at the bifurcation, will be a definite advance. Furthermore, long-term stenting is going to become increasingly popular. With the interventional radiologist doing such resourceful work in some of these patients, as Dr. Tompkins said, any operation on sclerosing cholangitis should assure a premanent approach to these ducts so that the radiologist can manipulate them more frequently.

Someone has already mentioned Ernie Ring. He takes care of one of my patients who has had multiple operations. Since he has been taking care of him—dilating ducts and replacing tubes—the patient's jaundice has disappeared.

One of the difficulties, of course, as we talk about liver transplants, is when to make the decision to perform the transplant. Dr. Cameron pointed out that if the patient is developing progressive cirrhosis, that probably is the time. I think it is very difficult to say this is correct, because the interval that a patient may undergo with no symptoms, or relatively minor symptoms, may be long. I have had one patient go 19 years without symptoms, but when he returned he had such progressive cirrhosis and portal hypertension that he was not a candidate for liver transplantation.

Having started this discussion by saying that I promised myself never to talk or write about sclerosing cholangitis again, I hope that Dr. Cameron and his group, as well as others, will continue to study this problem.

DR. JOHN W. BRAASCH (Boston, Massachusetts): I appreciate this opportunity to discuss this paper.

When Dr. Cameron speaks about intubation of bile ducts with Silastic tubes with or without operation, I listen, because he has had perhaps the largest experience—in this country and outside this country—with this particular technique in managing strictures.

Sclerosing cholangitis, as has already been pointed out several times this morning, is a kind of mystery disease. The preoperative diagnosis is strictly radiologic. We don't know the cause; and then the condition shades off into carcinoma of the duct, primary biliary cirrhosis, traumatic strictures, and chronic stone cholangitis. In fact, recently it has been pointed out that patients with AIDS may show this very peculiar type of bile duct reaction.

Our experience parallels Dr. Cameron's except that we have perhaps paid more attention to the presence of a major stricture than to the presence of cirrhosis. We try to save as much of bifurcation as one can, and it is possible in some of these patients not to remove the whole extrahepatic biliary system there, and thus get away with a lesser resection.

We do use the anastomosis, and we do stent, but perhaps for not as long as Dr. Cameron does, because we are a little afraid of the complications of chronic stenting.

In concluding, I would like to ask one question, and that is: How do you recognize the cirrhosis that would point you more towards a liver transplant than a reparative operation? We have had problems with biopsy material in estimating the degree of cirrhosis. In our experience, a small piece of tissue frequently does not give you the whole picture of the liver.

I have enjoyed this paper very much.

DR. C. RANDLE VOYLES (Jackson, Mississippi): I, too, have watched the work of Dr. John Cameron since the early 1980's and I applaud him for his update today.

He has been a pioneer in the work of the surgical approach to sclerosing cholangitis, and I have applied some of the concepts that he has utilized in Jackson, Mississippi, my first exposure being with Les Blumgart in London.

The basic concept is to transplant when the liver damage is irreversible; if you have hepatic reserve with a bad extrahepatic duct, then replace the extrahepatic duct.

I have two questions based on my experience with these patients. Number one, we know cirrhotics don't do well with any operation, much less extrahepatic duct replacement. Of your noncirrhotic patients, can you look at the cholangiograms and predict which patients are going to do well? I suspect those with dilated intrahepatic ducts are a significantly different group from the patients that have diffuse intrahepatic disease.

Secondly, what is the natural history of your noncirrhotics that have the operation? You have presented data regarding bilirubin out to five years. How quickly do these patients develop frank cirrhosis, impaired liver function, and portal hypertension? I suspect on the basis of your preoperative cholangiograms that you may be able to identify some long-term winners; how many of your patients are well at five years?

DR. HARVEY J. SUGERMAN (Richmond, Virginia): Two years ago before the society, we presented data on extrahepatic biliary obstruction secondary to chronic pancreatitis, and I notice from this presentation that four of the 31 patients had biliary obstruction secondary to chronic pancreatitis, and I would like to have just a little better feel for what evidence of sclerosing cholangitis was present in that group of patients, since extrahepatic biliary obstruction secondary to chronic pancreatitis is a very common event.

I presume that this was a totally separate subgroup of that group of patients; and secondly, it has been my impression from our liver transplanters that certainly the greatest difficulty (the greatest blood loss) has been in those patients who have had to have their liver transplants after one or more previous operative procedures. I just wonder about the difficulties in patients who have undergone their transplantation and have previously undergone this operative procedure in terms of the technical difficulties and blood loss in that group of patients, and wonder if it wouldn't have been better to use percutaneous biliary dilatation with Ring catheters.

DR. JOAQUIN S. ALDRETE (Birmingham, Alabama): I think Dr. Cameron's paper is not only very important, but also timely because, at the present time, one of the greatest decisions concerning patients with sclerosing cholangitis is whether to send them directly to liver transplantation or treat them by some other operative method.

Having the advantage, or perhaps the misfortune, of being involved in our institution in both of these methods of treatment with such patients, I would like to offer some comments and ask a question of Dr. Cameron. I totally agree with his criterion for selection of patients to be treated without transplantation. It seems to me that there are two types of patients with sclerosing cholangitis. First, there are those that have a rather rapid progression into the terminal states of the disease. They promptly develop biliary cirrhosis, and there is no question that such patients should directly go the route of hepatic replacement.

Other patients, however, have a slower course in the deterioration of their hepatic function, and, particularly if they have segments of dilated bile ducts, our experience, (although with a smaller number of cases), has been similar to that reported by Dr. Cameron. These patients with sclerosing cholangitis that have localized segments of stenosis, usually located near the area of the bifurcation, are the ones that can be treated by intubation.

We have seen four such patients that we have followed from one to six years after doing a similar intubation procedure, with the only difference being that the stents we used were completely internal and permanently implanted. I have been very satisfied with the results obtained with these patients.

In these days, the identification of this small but existent population of patients is important because there is a tendency to send all patients with sclerosing cholangitis directly to the transplant team. Although the results are spectacular when the transplant works, one must remember that there is still 20–30% mortality, and the survivors require per life immunosuppression that is sometimes expensive and cumbersome. Although I am one of the greatest enthusiasts of liver transplantation, I think the possibility of safely postponing or avoiding it, with the patient alive and functioning, should be pursued.

The careful and precise operative technique described by Dr. Cameron can help prevent some of the technical problems if subsequent transplantation was required. I noticed that he percutaneously places a catheter in the bile duct so that it can be readily identified. He cuts the bile duct very early and does all the dissection very close to the hilum of the liver, leaving the portal vein and the hepatic artery relatively undisturbed to facilitate their discussion when subsequent transplantation of the liver is required.

The problem is in selecting the patients for the intubation method, but Dr. Cameron has been very specific in his criterion.

Another problem is that some of these patients develop or have carcinomas of the bile ducts concomitant with the primary sclerosing cholangitis. In fact, the last patient in whom we performed a transplantation for this disease had a carcinoma of the bile ducts that we could not detect before operation. So, my question to Dr. Cameron is:

How often have you seen carcinomas in these patients? Again, I congratulate you on a superb piece of work and for pointing out that there are checks and balances, and that not everything is clear-cut in the operative treatment of sclerosing cholangitis.

DR. HENRY A. PITT (Closing discussion): Dr. Tompkins asked about the selection criteria. Patients were selected for this operation if they had persistent jaundice or recurrent cholangitis and the major point of obstruction was near the hilum or more distally. In general, we have reserved this operation for patients with a total bilirubin of more than 5 mg/dL that persists for at least 3 months. In only two of our patients was the indication for surgery recurrent cholangitis without persistent jaundice.

Dr. Tompkins also asked about balloon dilatations as a treatment for patients with sclerosing cholangitis. Over the past 8 years, we have managed approximately 20 patients at Johns Hopkins with percutaneous transhepatic balloon dilatation of biliary strictures. Most of these strictures have been postoperative, whereas only two patients with sclerosing cholangitis have been initially managed with this technique. Both of these patients had persistent symptoms and eventually came to surgery. Moreover, we have been impressed that balloon dilatation can be quite painful. As a result, several patients have requested general anesthesia when repeat dilatations were recommended. Thus, if a nonoperative technique requires multiple procedures and anesthetics, we wonder whether one operation isn't better.

Three of the 31 patients had problems with cholangitis after surgery. These episodes usually result from tube occlusion and can be managed with tube change and a short course of systemic antibiotics. Most of the patients have their tubes changed electively every 3 or 4 months and do not take oral antibiotics in the interim. However, three of our patients have required more frequent tube changes and chronic oral antibiotics to prevent recurrent cholangitis.

Several discussants asked about hepatic transplantation, and their questions implied that morbidity and mortality of liver transplantation might be increased if the patient has had prior biliary surgery. In discussions with Dr. Starzl, he states that the operation is technically more difficult if the patient has had prior biliary tract surgery. However, in terms of 3- and 5-year survival, the bottom line seems to be unaffected by prior biliary surgery in adults with sclerosing cholangitis. Yet at the University of Pittsburgh, prior surgery for biliary atresia does adversely affect the long-term outcome of liver transplantation in children with this problem.

Dr. Warren and others asked about the etiology of sclerosing cholangitis. A growing body of data now suggest that the etiology of sclerosing cholangitis is multifactional and that sclerosis of the bile ducts may represent the end-stage of many diseases. In some patients, including those with inflammatory bowel disease, the etiology may be an autoimmune phenomenon. In a small percentage of patients, bacterial infections or congenital anomalies may result in sclerosing cholangitis. We have also described patients with both histiocytosis X and sclerosing cholangitis. Recent data, including some from AIDS patients, also suggest that viral infections can result in sclerosing cholangitis. Presently, we are treating the end-stage of this disease. We need to learn more, however, about the etiology so that we can eventually develop specific therapies to prevent the problem.

Dr. Warren and others asked about the use of long-term stents and the timing of liver transplantation. We have left the stents in our patients indefinitely to provide access for removal of biliary sludge or stones. Postoperative balloon dilatation of intrahepatic strictures can also be accomplished via these access ports. With respect to subsequent liver transplantation, the indications for these patients are the same as for those without prior surgery. In general, these patients become candidates for transplantation when they have established cirrhosis and progressive liver failure. One pitfall to be aware of, however, in diagnosing secondary biliary cirrhosis is the atrophy/hypertrophy complex. Some of these patients with long-standing obstruction of only one side of the liver will develop cirrhosis in one lobe and hypertrophy in the other. Thus, if the right lobe is atrophied and biopsy from that lobe demonstrates cirrhosis, an additional biopsy from the left lobe may be necessary to provide the entire picture.

Dr. Braasch suggested that his approach is very similar to ours. I believe I have already answered his question about cirrhosis. Obviously, we rely upon the expertise of our hepatic pathologists, who review these biopsies very carefully and help us to make clinical decisions.

Dr. Voyles asked whether we can predict outcome from the patient's cholangiographic pattern. The one group that has done well uniformly is the small subset of patients in whom the disease involves primarily the common bile duct. Some, but not all, patients with diffuse intrahepatic involvement have had a poor outcome. Thus, despite moderate intrahepatic disease, if the patient has a major point of hilar or extrahepatic obstruction but no evidence of cirrhosis on liver biopsy, we would recommend our biliary reconstructive approach. In some patients, we have even observed improvement of the intrahepatic cholangiogram after surgery.

Dr. Voyles also asked about the quality of life of the long-term survivors. The majority of these patients are really quite well. They have their tubes changed three or four times a year, but this procedure is frequently done on an outpatient basis.

Dr. Sugerman asked about the four patients with associated chronic pancreatitis. These patients had typical sclerosing cholangitis with strictures above the intrapancreatic portion of the bile duct. Many patients with sclerosing cholangitis have sludge in their bile ducts as a result of the strictures and stasis. We believe that passage of this debris may cause a "gallstone" type of pancreatitis. In addition, the biliary strictures associated with this disease may also involve the sphincter mechanism. One or both of these factors may cause pancreatitis in patients with sclerosing pancreatitis. Moreover, by dividing the bile duct and diverting the flow of bile, our operation may actually prevent ongoing "gallstone" pancreatitis.

We would agree with Dr. Aldrete that both biliary tract surgery and hepatic transplantation should be available for patients with sclerosing cholangitis. We are performing both procedures at Johns Hopkins. We recommend transplantation for patients with established cirrhosis. However, this procedure and the associated immunosupression have real morbidity and mortality. Therefore, we feel that biliary reconstruction is preferred for patients who have not yet progressed to cirrhosis.

Dr. Aldrete also commented on concomitant cholangiocarcinomas. We have presented 31 patients. However, two additional patients not included in this series were initially thought, on the basis of their cholangiograms and other clinical data, to have sclerosing cholangitis. At surgery they had cholangiocarcinomas at the hilum, in addition to sclerosing cholangitis. We believe that this association is another reason why patients should be managed initially with resection of the hepatic duct bifurcation and biliary reconstruction, rather than with either balloon dilatation or hepatic transplantation.

CLASSIFIED AD SECTION

Classified advertising is avabilable in **ANNALS OF SURGERY** for those recruiting personnel or interested in obtaining positions. Display space is available for those desiring greater visibility or more space for their message.

Classified ad copy, like other advertising copy, will be reviewed for approval prior to publication.

Classified Rates: $9.00 per line or fraction of line. The average line will be 62 characters.

Box Numbers: Replies may be directed via Box # to J.B. Lippincott Company, at an extra charge per insertion of $6.50 to cover handling costs in forwarding such replies to the advertiser.

How to Order: Send typewritten text copy for the ad with remittance in full to:

ANNALS OF SURGERY

East Washington Square
Philadelphia, Pa. 19105
(215) 238-4215

Deadline: Copy received by the 15th of month will run in the second following month's issue, e.g. November 15th for January issue. Ads received after the 15th will run in the next available issue.

GENERAL SURGEONS—Newly established prepaid group practice desires to begin offering general surgery services. Looking for general surgeons interested in establishing and building a department. Physicians must be from high quality residency programs. Positions available immediately. Address C.V. to: **Larry A. Oates, M.D., Regional Medical Director—ANS, Carolina Permanente Medical Group, P.A., 3120 Highwoods Boulevard, Raleigh, North Carolina 27604, (919) 878-9870.**

Chairman, General Surgery Department—San Bernardino County Medical Center is seeking a new Chairman of Dept. of General Surgery. Individual will have major clinical and academic responsibilities at SBCMC and must qualify for academic appointment at Loma Linda University School of Medicine. Inquiries should be accompanied by curriculum vitaes and addressed to: **M. Kenneth Mudge, M.D., Chairperson, Dept. of General Surgery Search Committee, c/o Medical Director's Office, Rm. 101, San Bernardino County Medical Center, 780 E. Gilbert St., San Bernardino, CA 92404.** Equal opportunity employer.

KANSAS: We are seeking a general surgeon interested in a full-time private practice opportunity in the greater Kansas City area. For further information, please send current CV to: **Linda Smith, Central Business Services, Inc., 3101 Broadway, Suite 1000, Kansas City, Missouri 64111; or call 1-800-821-5147 or 816-561-1025.**

All Surgical Specialties, Nationwide. Excellent quality of life and compensation. Dr. Len Goodman, SMA, P.O. Box 25786,

---

Stanford University School of Medicine invites nominations and applications of candidates for appointment to the full-time faculty as Professor and Chairman of the Department of Surgery. Interested candidates should send a curriculum vitae and supporting documentation to: **Norman E. Shumway, M.D., Ph.D., Chairman, Search Committee for Surgery, Department of Cardiovascular Surgery, Stanford University School of Medicine, Stanford, CA 94305.** Stanford University is committed to increasing representation of women and members of minority groups on its faculty and particularly encourages applications from such candidates.

GENERAL SURGEON—B.C./C.E. with interest in peripheral vascular surgery and noninvasive lab to join two busy general surgeons in medium size midwestern city. Needed by July, 1989. Close to metropolitan area and two university medical centers. Excellent hospital facilities with young, progressive medical staff. Benefits and salary leading to partnership opportunity. Send CV to: **President's Office, Memorial Hospital, 450 E. 23rd, Fremont, Nebraska 68025.**

MOUNT SINAI MEDICAL CENTER/SURGICAL ONCOLOGIST—Wanted general surgeon, board certified or eligible, with special interest in Head & Neck surgical oncology. Individual will work with Senior Surgical Oncologist to further develop Head & Neck program and do some general surgical oncology. Responsibilities will include patient care administration, research, and education of both medical students and surgical residents in fully approved surgical residency training program. Successful applicant should have bibliography related to field of interest. Address inquiries to: **Victor D. Dembrow, M.D., Director of Surgical Oncology, Mount Sinai Medical Center, 4300 Alton Road, Miami Beach, Florida 33140.**

VASCULAR SURGEON—Board certified/eligible vascular surgeon needed to join 300 physician multi-specialty group in Sacramento, CA. Competitive salary and excellent fringe benefits. Ninety miles from Sierra skiing and San Francisco. California license required. Send curriculum vitae to: **Mrs. Carolyn Whelan, The Permanente Medical Group, Inc., P.O. Box 254999, Sacramento, CA 95865-4999.** EOE.

TRAUMA/CRITICAL CARE SURGEON—The University of Chicago Department of Surgery is actively seeking a full-time Trauma/Critical Care surgeon to participate on an active Trauma Service and direct Surgical Intensive Care as a part of a Multi-Disciplinary Critical Care Program. The applicant should be Board Certified in General Surgery and have training or experience in Trauma and Surgical Critical Care. Please send inquiries and CV to: **Thomas Vargish, M.D., Trauma/Critical Care, Department of Surgery, University of Chicago, 5841 South Maryland Avenue, Chicago, Illinois 60637.** The University of Chicago is an equal opportunity/affirmative action employer.

SURGICAL ONCOLOGIST OR GENERAL SURGEON—Outstanding opportunity for a well trained Surgical Oncologist or General Surgeon to affiliate as an Associate with a premier Northern California surgical practice located in the North Sacramento area. Generous salary and benefits. Partnership offered 2-5 yrs. A turn-key situation located in a beautiful growing community. **Call collect Physician Relations Manager 916-537-5009.**

Immediate Opportunity

Surgery

Group or solo practice

Affiliate with our progressive, well-equipped hospital and help us meet the needs of the 55,000 residents of our hospital district. Renovation ($6.6 million) of major areas including surgery now under way.

Income guarantees, relocation assistance and practice enhancement services provided.

Send current CV or call collect –

Michael R. Fraser
Administrator
Kennewick General Hospital
900 S. Auburn
Kennewick, WA 99336

509/586-8406

BC/BE General Surgeon to associate with two active internists in NE Wisconsin. New clinic and modern hospital with state of the art ICU. **Reply Box AS588B. J.B. Lippincott Co., East Washington Square, Philadelphia, Pa. 19105.**

VASCULAR SURGEON: Full time academic position. Excellent opportunity with large clinical volume and funds for research. Candidate should be eligible for appointment as Assistant Professor of Surgery, Suny Stony Brook. Attractive area on North Shore of Long Island. Must be board certified or eligible for vascular certificate. Excellent salary/benefits. Send curriculum vitae to: **Leslie Wise, MD, Chairman-Department of Surgery, Long Island Jewish Medical Center, 270-05 76th Avenue, New Hyde Park, N.Y. 11042.** An equal opportunity employer.

This Publication is available in Microform.

THE BILLINGS CLINIC

Certified Cardiopulmonary Perfusionist

Progressive medical center in the Northwest area is seeking a certified Cardiovascular Perfusionist. Qualifications: Applicant must be certified or eligible for certification as a Perfusionist; licensure as a registered nurse is helpful but not required; demonstrated ability to work effectively with cardiovascular team. Salary commensurate with experience, excellent benefits.

Forward resume to:

Personnel Manager
The Billings Clinic
P.O. Box 35100
Billings, MT 59107-5100.

MOUNT VERNON HOSPITAL
FAIRFAX HOSPITAL SYSTEM

ONCOLOGY FELLOWSHIPS

Positions are available to physicians who are licensed to practice medicine in the United States and have at least two years of training in medicine or surgery.

The oncology training offers a one year fellowship beginning July 1, 1988 and July 1, 1989. The program consists of primary clinical responsibility of both in-patients and out-patients undergoing treatment with various biologic response modifiers and chemotherapeutic agents.

Continuity of patient care, principles of patient management, and design and conduct of clinical trials are stressed. Seminars and conferences on biostatistics, immunology, cell biology, molecular biology, clinical pharmacology, and diagnostic pathology and radiology are given regularly.

The annual salary is $45,000.00, including medical and dental insurance, life insurance, vacation, and sick leave. In addition, moving and travel expenses are available.

For further information please contact:

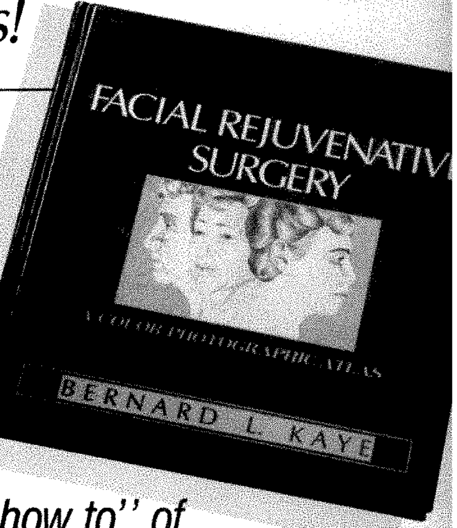
FACIAL REJUVENATIVE SURGERY

A Color Photographic Atlas

BY BERNARD L. KAYE, M.D.

With a section by Scott L. Blonder, M.D.



*A remarkable full-color atlas describing the "how to" of facial rejuvenative surgery...**with 510 superb full-color illustrations!***

The "how to" of face lifts and ancillary rejuvenative procedures

This full-color photographic "how to" atlas takes you step by step through Dr. Kaye's techniques in face lift surgery and other rejuvenative procedures, techniques that have earned the author an international reputation in plastic surgery. Full-color intraoperative and "before and after" photographs are supplemented by concise narrative text and original schematic diagrams showing important points of each procedure. A full discussion of anesthesia and support systems is also included.

Full-color intraoperative photographs with a uniquely realistic view

The physical orientation of most of the intraoperative photographs is as though you were looking over Dr. Kaye's shoulder, as a visitor in the operating room would view the procedures. Images are shown in the same orientation as would apply on the operating table—horizontal, not vertical—so that there is no need for you to transpose mentally the position of the patient when repeating the techniques described in the book.

A comprehensive visual presentation of Dr. Kaye's personal techniques

In the first chapter, Dr. Kaye describes and discusses the supportive and anesthetic techniques and adjuncts that he uses for face lifts and other related procedures. In this chapter, Dr. Scott Blonder, anesthesiologist, also discusses anesthetic techniques which are particularly useful for aesthetic rejuvenative facial surgery, and which permit a smooth anesthetic course without excessive bleeding, especially when using general anesthesia, and a quick, smooth awakening and recovery from general anesthesia without bucking or gagging.

Part I. Standard Procedures, describes the face lift and neck lift operation. It includes the usual techniques as well as variations and modifications for special situations. **Part II, Ancillary Procedures,** covers the various ancillary rejuvenative procedures which Dr. Kaye performs along with face and neck lift operations.

About the author

Bernard L. Kaye, M.D., *is Clinical Professor of Surgery (Plastic), University of Florida College of Medicine at Jacksonville, Jacksonville, FL, and a world-renowned authority on plastic surgery.*

Management of Variceal Bleeding in Patients with Noncirrhotic Portal Vein Thrombosis

W. DEAN WARREN, M.D.,* J. MICHAEL HENDERSON, F.R.C.S.,* WILLIAM J. MILLIKAN, M.D.,*
JOHN T. GALAMBOS, M.D.,† and F. CURTIS BRYAN, B.A.

From the Departments of Surgery and Medicine,† Emory University Hospital, Atlanta, Georgia*

Since 1971, 70 patients have been seen at Emory University Hospital with gastroesophageal varices secondary to extrahepatic portal vein thrombosis (PVT). Thirty-seven of these patients had had prior major operative therapy. In only three patients (8%) was shunt surgery successful, and there was a high incidence of rebleeding, other morbidity, and mortality. Of especial note are the serious consequences of simple splenectomy; splenomegaly and thrombycytopenia should rarely, if ever, be used as indication for splenectomy in portal hypertension. In 1977, the use of selective distal splenorenal shunt (DSRS) was begun at Emory in this population and a selective shunt has been possible in 24 of 29 patients (83%) who had had no prior operative therapy. Results have been excellent with a greater than 90% patency rate, long-term portal perfusion in all, no encephalopathy, and late rebleeding in one patient. Quantitative studies at 3–6 years show stability of liver function, significant decrease in spleen size, and rise in platelet count. However, long-term follow-up (>15 years) is required in PVT patients before definitive assessment can be obtained. A specific problem of the PVT patient is late shunt stenosis which requires close observation; dilatation of the shunt was performed in six of the 24 patients with a patent shunt. Poor results with non-shunt operative procedures in PVT were again documented. The proper role of endoscopic variceal sclerotherapy is not yet clear, but appears to be an excellent addition to the therapeutic options. In conclusion, for patients with a patent splenic vein, initial therapy should be a selective shunt; for patients without a patent splenic venous system, endoscopic sclerotherapy is the procedure of choice.

EXTRAHEPATIC PORTAL VEIN THROMBOSIS (PVT) in the noncirrhotic is a relatively uncommon cause of portal hypertension in this country. Effective management of bleeding varices in PVT patients is especially important as progressive liver deterioration with death from hepatic failure is not the limiting factor in survival, as in patients with cirrhosis, chronic active hepatitis, or other severe hepatic disease. When first seen, PVT patients are usually young, in good general health, and capable of normal educational and work achievements if variceal hemorrhage is controlled and therapeutic endeavors do not induce other serious problems.

In earlier papers we and others have emphasized the unique physiology of PVT patients as related to liver blood flow.[1-3] To most surgeons a diagnosis of portal vein thrombosis signifies an absence of portal perfusion of the liver and there is no concern about shunting all portal flow into the systemic venous circulation.[4-11] The portacaval, mesocaval, and central splenorenal shunts are examples of this type of operation, which we refer to as total shunts. In 1893, Pavlov and his associates published a paper in which they studied the Eck fistula (portacaval shunt) in dogs.[12] In this paper they defined clearly the syndrome of portal-systemic encephalopathy and this aspect of the work is often cited in the literature. They also studied carefully an interesting subset of animals, those which survived and prospered, regaining their normal health; autopsy studies revealed occluded or markedly stenosed shunts in all. Also noted was the development of large *hepatopetal* collateral veins (the portal vein was ligated as part of the Eck operation) which restored some portal perfusion of the liver. They concluded that a modicum of portal venous blood perfusing the liver was necessary to ensure health and long-term survival of these experimental animals.

Presented at the 100th Anniversary Meeting of The Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Supported by General Clinical Research Center Grant RR00039.

Reprint requests and correspondence: W. Dean Warren, M.D., Whitehead Professor and Chairman, Department of Surgery, Emory University Hospital, 1364 Clifton Road, NE, Atlanta, GA 30322.

Submitted for publication: December 16, 1987.

The human with extrahepatic portal vein thrombosis fits this model, with high pressure in the general portal venous system (including the spleen), a normal hepatic sinusoidal pressure and *hepatopetal* collateral flow. The pattern in cirrhosis is markedly different with a high hepatic sinusoidal pressure and *hepatofugal* collaterals. When the hepatic sinusoidal pressure is essentially the same as splenic pulp pressure, there is no hemodynamic predisposition for collateralization to the liver *versus* the spleen. This latter hemodynamic pattern is seen after a selective distal splenorenal shunt (DSRS) in patients with PVT. In patients with PVT, hepatopetal collaterals are easily demonstrated by angiography and are usually designated "cavernous transformation of the portal vein." One aim of this study is to determine if long-term hepatic portal perfusion is sustained after DSRS in patients with PVT and if such flow is clinically relevant.

It is well known that splenectomy will alleviate the pancytopenia of portal hypertension.[5,7,8] However, splenectomy is rarely indicated because the risk of the splenomegaly and pancytopenia is low, and the risk (acute and chronic) of the operation is high. In addition, in some patients, the splenic vein is the only portal tributary suitable for shunting and splenectomy leads to loss of this option for control of variceal bleeding. As emphasized in many papers,[5,10,13] the most ill-advised of all interventions in portal hypertension is splenectomy for a low platelet count in a child with a patent splenic vein. A second question then arises: is splenectomy ever indicated in extrahepatic PVT?

There have been a number of groups advocating nonoperative therapy in patients with PVT,[14–17] because the tolerance for bleeding is great, and shunt failure has occurred historically in a high percentage of surgical patients. This position has been greatly strengthened by the reintroduction and marked improvement in endoscopic variceal sclerotherapy. The success at Emory of sclerotherapy for bleeding varices in other conditions has also stimulated our interest in the role of sclerotherapy in the management of patients with PVT.

Materials and Methods

This is a prospective but nonrandomized study of patients with portal hypertension and variceal bleeding secondary to extrahepatic PVT in the absence of cirrhosis, cancer, or other liver pathology, such as polycystic disease. We have also excluded two important related conditions, isolated splenic vein thrombosis and idiopathic portal hypertension (portal sclerosis). The purpose of this work is to reassess our previous concepts regarding pathophysiology, diagnosis, and management of PVT and extend the duration of our follow-up.

All patients were seen and studied at Emory University Hospital in Atlanta, a tertiary care referral center for adults. The first distal splenorenal shunt for PVT in Atlanta was performed in 1977, but we have elected to include all patients seen at this hospital since 1971, the year a general study of portal hypertension was begun.

Evaluation of patients included liver biopsy and angiography in addition to conventional clinical and laboratory procedures. Angiographic evaluation consisted of splenic and superior mesenteric artery injection with both arterial and venous phase filming. This was accompanied by hepatic and renal vein angiography and manometry; in some patients direct splenoportography was necessary for more accurate delineation of the venous anatomy. Endoscopic procedures were used frequently, both for diagnostic and therapeutic purposes. Quantitative tests followed a protocol previously published by us.[18] Liver function was assessed by galactose elimination capacity (GEC) and liver blood flow was measured by low-dose galactose clearance. The estimation of portal perfusion of the liver was limited to angiography following the departure to another University of the Faculty member responsible for our radionuclide technique. Cardiac output was measured by both echocardiography and radionuclide angiocardiography. Calculation of liver and spleen volumes by computerized tomography were also studied by techniques previously reported.[18] Assessment of encephalopathy included clinical evaluation, EEG, blood ammonia, and trail testing.[19]

A subset of six patients having DSRS have had preoperative and serial postoperative quantitative evaluation for up to 6 years. The purpose of this "in depth" study has been to document the hepatic function and hemodynamic effects of DSRS. These patients are believed to be representative of the overall DSRS group, and have been emphasized in this analysis because they have been available for repeated study of several years' duration.

Patient Population

Seventy consecutive patients with PVT admitted to Emory University Hospital since 1971 form the patient base for this investigation. Some general characteristics of these patients are presented in Table 1. One feature of crucial importance in management is the presence of a major tributary of the portal system that remains patent and functional. The two most important vessels in this regard are the splenic and superior mesenteric veins; also of value are gastroepiploic, left gastric, and inferior mesenteric veins. The analysis of our data may be somewhat anomalous in that 37 patients (53%) had undergone major operative therapy before being seen at Emory. In only three (8%) of these patients was there a normal tributary found, facilitating a DSRS in one patient and a mesocaval shunt in the two others.

Another important determinant in this group was absence of the spleen that was confirmed in 29 patients at the time of referral (Tables 1 and 2). In 24 patients, simple splenectomy had been performed (frequently as treatment for hypersplenism) and in five patients, a central splenorenal shunt had been attempted. Unfortunately in none of the patients having splenectomy in other hospitals do we have unequivocal data as to the state of the portal circulation before the splenectomy. Table 2 outlines the nature of the previous operations in this group.

In 33 patients there had been no prior major operative therapy and 29 of these were seen after the decision to use DSRS in PVT patient therapy. Selective shunts are the procedure of choice for our group as we attempt to achieve both decompression of gastroesophageal varices and maintainance of portal flow to the liver. In these 29 patients, some type of selective shunt was achieved in 25.

There was equal distribution between males (36) and females (34) and the mean age at the time of first admission to Emory was 35 years (Table 1). This in all probability reflects the adult nature of the patient population at Emory University Hospital since we do not have a pediatric service at this Institution. Patients who had had prior operative therapy at other institutions were about 10 years older than those first treated at Emory.

Results

The excellent long-term outlook of patients with PVT has been emphasized by some authors and questioned by others. Our population of older patients showed some hazards of the disease not often seen in children. These included venous infarction of the small bowel, death from pulmonary emboli, massive hemobilia, and late, severe encephalopathy requiring closure of a central splenorenal shunt. Nevertheless, the outlook for our PVT patients is certainly better than that of the patients with chronic liver disease, as more than 90% survive for 5 or more years after initial therapy.

Patients with PVT often appear to be in excellent health if seen before a complication arises. Careful study, however, reveals the liver to be smaller than normal, as is total hepatic blood flow. The liver biopsy results are essentially normal as are the ordinary liver test results. True liver function test results are on the lower side of normal.

Exploration for shunt	1
Total	37

Mortality

Six of the 70 patients have died (Table 3). Two of the deaths were due to unrelated problems, cancer of the brain and pancreas. One was due to rebleeding, in a complex patient described below. There was a single operative mortality (1.8%) in a 62-year-old patient who had bled through sclerotherapy with a recent failed attempt at a portacaval shunt at another hospital. An urgent attempt to create a makeshift shunt was unsuccessful, and splenectomy (the splenic vein was thrombosed) and gastric devascularization were performed. He died in the hospital of bilateral pneumonia and general sepsis.

Therapies

The selection of type of intervention (if any) was determined by our assessment plan as shown in Figure 1. The results achieved with the patients in different ana-

6	69/F	Brain tumor. Splenectomy/devascularization 3 years prior.

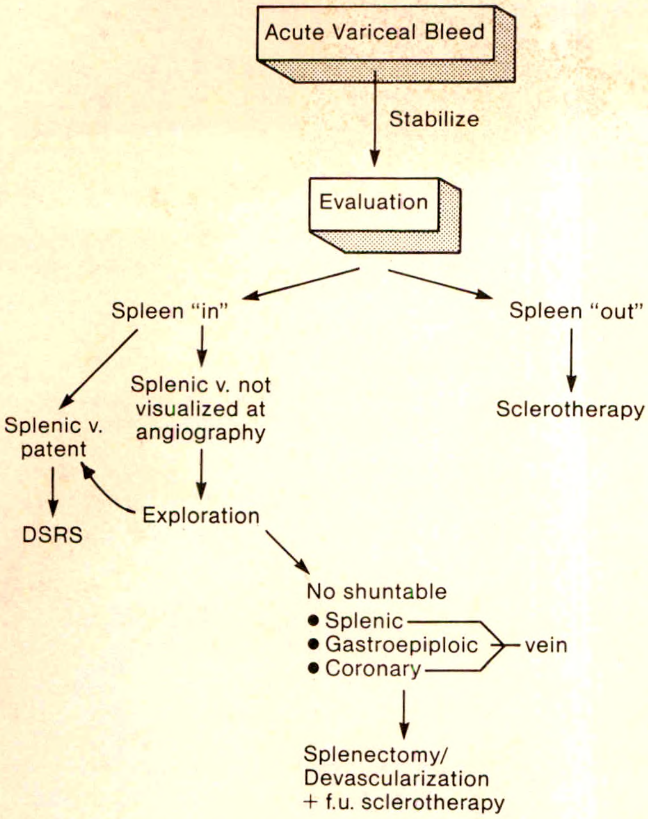

FIG. 1. A flow diagram showing our recommended management. Management options are dictated by prior surgical therapy and patency of portal venous tributaries.

tomical categories and prior therapies are as follows (Table 4).

Shunts

Selective shunts. Twenty-nine patients had exploratory surgery with intent to create a selective shunt, and in 25 this was successful. In the shunt group there were 19 DSRS, three distal splenocaval shunts, two gastroepiploic-renal, and one left gastric to renal shunt. One of the 19 DSRS was performed in a 20-year-old woman in whom a splenic transposition procedure (splenopneumopexy)[20] had been performed 20 years previously.

Patency of shunt. There was only one early thrombosis in the shunt group, a splenocaval anastomosis, for an overall patency rate of 96%. One DSRS had a successful early revision for a patent but kinked splenic vein, which had resulted in outflow obstruction and early postoperative bleeding. A rather specific problem in the PVT patients is the need for re-evaluation of the shunt at 3–6 months for possible stenosis. Patients whose splenic vein shows evidence of prior phlebitis are particularly at risk, and if stenosis is documented at shunt catheterization, dilatation of the anastomosis is indicated (Figs. 2 and 3). This was necessary in six of the 25 patients, a much higher incidence than seen following shunts for cirrhosis or other hepatic problems. Dilatation failed in one of the gastroepiploic shunts and revision of the anastomosis was required at 1 year. This increased tendency to stenosis is believed to be related to the thrombophlebitic process within the portal venous system. Our practice of interrupting the anterior row of sutures in the anastomosis probably facilitates the use of postoperative dilatation.

TABLE 4. *Definitive Bleeding Control, Deaths and Follow-up Status by Main Therapy Groups*

Management	No. of Patients	Rebleeding	Deaths	Loss to F/U
DSRS	25	1	1	1
Splenectomy	10	6	2	2
Devasc/sclerosis	10	5	3	2

Mesocaval	2	1	0	0
No therapy	7	0	0	1

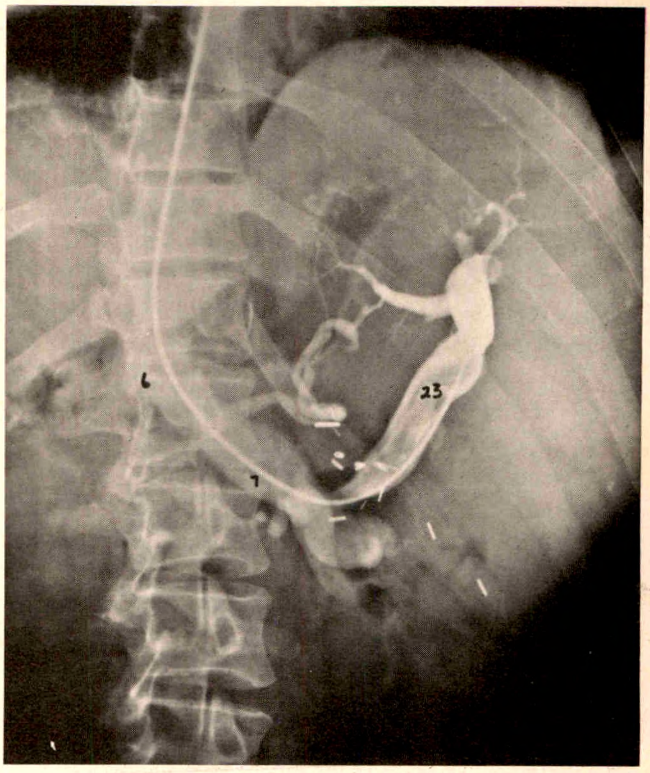

FIG. 2. Stenosis of a DSRS 4 months after operation in a patient who had phlebitis of the splenic vein.

Portal perfusion of the liver. Portal perfusion of the liver *via* the portal venous collaterals was present in all patients immediately after operation. In 15 patients restudied from 6 months to 6 years later, this hepatic portal perfusion was sustained in every instance (Figs. 4 and 5), and bleeding controlled (Fig. 6). Proof of portal perfusion requires repeat superior mesenteric angiography in PVT patients.

Rebleeding. There have been three episodes of bleeding after operations. Two of these were in the early postoperative period, a phenomenon seen frequently in selective shunts. This was managed by revision of a kinked shunt in one patient, and by sclerosis in the other following documentation of shunt patency by catheterization. One patient bled at 1 year after a gastroepiploic shunt, which had required dilatation for stenosis. After the bleeding episode, a reoperation with reanastomosis was done successfully. The patient with a thrombosed splenocaval shunt has not rebled.

Encephalopathy. There has been no evidence of encephalopathy clinically, by EEG, or by trail testing thus far. However, the post-shunt period is still short, with the first patient just 10 years post-shunt.

Study group. The quantitative data on the six patients studied serially in depth is summarized in Table 5 and Figures 7 and 8. There is no significant change in GEC, liver volume, and portal perfusion. Liver blood flow shows a significant ($p < 0.05$) increase at late follow-up. Spleen volume, shown in Figure 7, shows a significant reduction ($p < 0.05$) from the preoperative mean (±SD) of 905 ± 540 cc to 472 ± 246 cc at 1 year and 337 ± 169

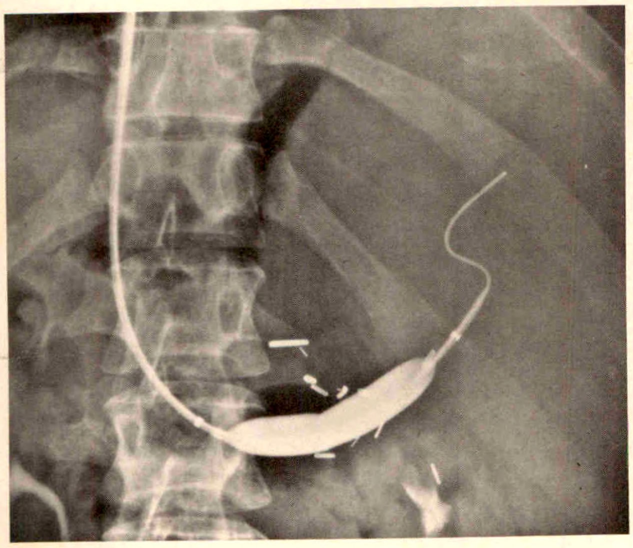

FIG. 3. Dilation of the stenosis was satisfactorily achieved with the balloon, shown in position across the splenorenal anastomosis.

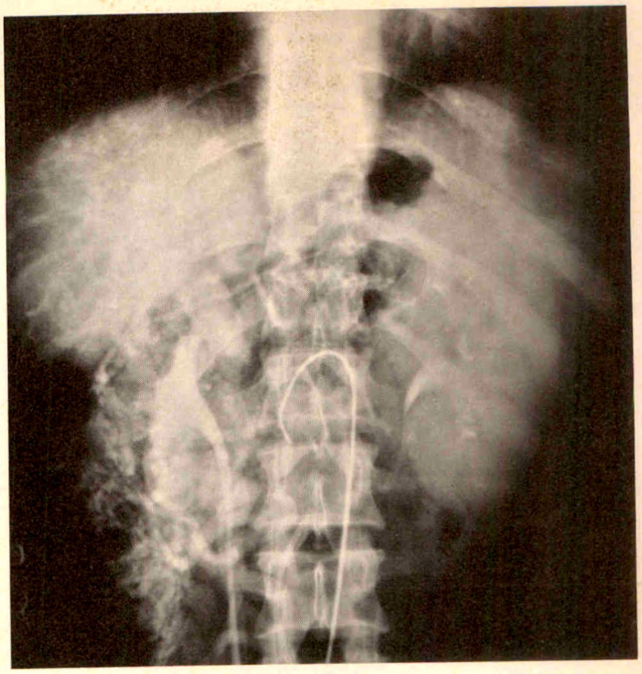

FIG. 4. Portal perfusion in portal vein thrombosis (preoperative). Venous phase of superior mesenteric artery injection showing cavernous transformation and excellent filling of all intrahepatic portal venous radicles.

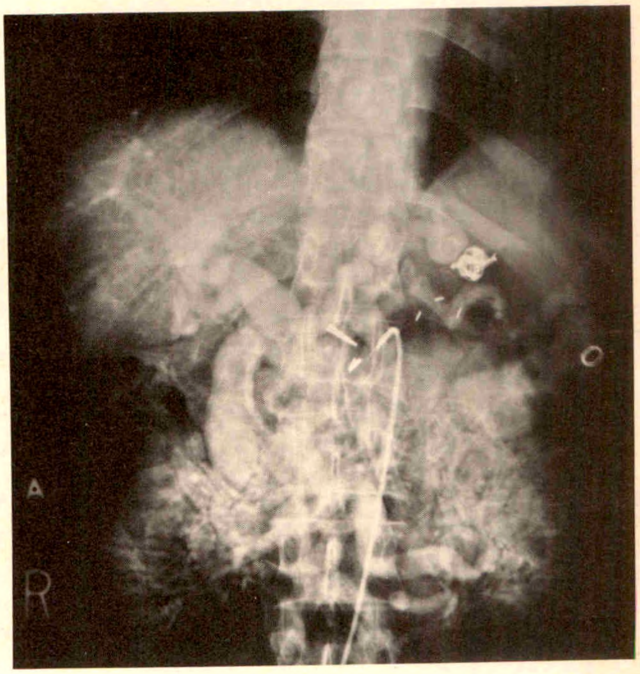

FIG. 5. The same study in the same patient 6 years after DSRS. Excellent portal perfusion is shown; the large hepatopetal collaterals are evident.

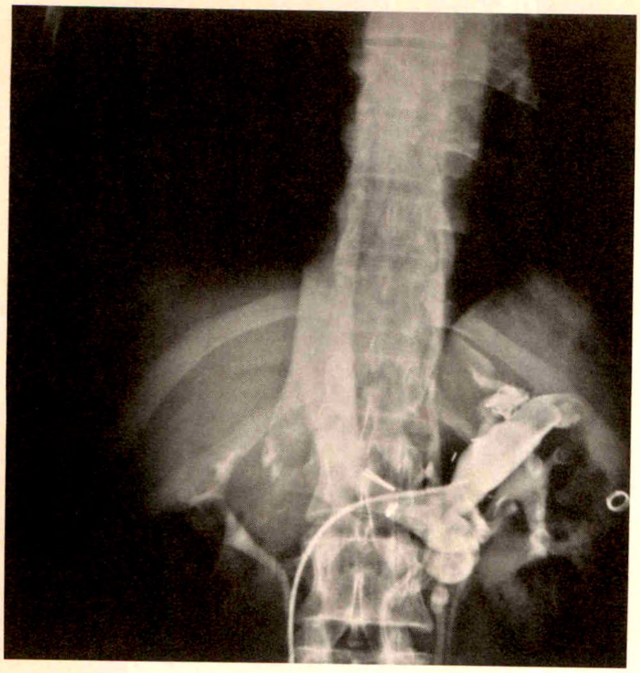

FIG. 6. Widely patent shunt at 6 years in same patient as Figures 4 and 5.

cc at mean 4.5 year follow-up. Platelet count increase, shown in Figure 8, is also significant ($p < 0.05$), rising from 99 ± 59 to 145 ± 46 and 183 ± 35 K/mm^2 at 1 and 4.5 years, respectively.

In addition, three patients in this group have had successful and uncomplicated pregnancies in the past 3 years. This is a further measure of return to normality after DSRS.

Other shunts. In two patients with prior splenectomy, a superior mesenteric caval shunt was possible. A Marion–Clatworthy vein-to-vein anastomosis was done in a patient who had rebled repeatedly after a splenectomy at age 15 years. At the time of shunting the patient was 56 years old and had received more than 100 units of blood over the post-splenectomy period. After shunting there has been no rebleeding and the shunt has been shown to be patent by angiography at 16 years. The patient has no clinical, psychometric, or EEG evidence of encephalopathy. She has had a mild hyperammonemia in recent years; the liver volume is 990 cc.

TABLE 5. *Data on Hepatic Function and Hemodynamics in 6 Patients Studied In Depth Before and Serially After DSRS*

DSRS (N = 6)	Before	1 Year	3–6 Years
GEC (mg/min)	392 ± 40	377 ± 66	403 ± 66
LBF (ml/min)	1069 ± 345	1078 ± 345	1500 ± 429*
Portal perfusion	1	1	1
Liver volume (cc)	1039 ± 242	1131 ± 195	1159 ± 169

* $p < 0.05$.

A second mesocaval shunt used a dacron interposition graft. This patient did well for 7 years and then rebled. Angiography revealed an occluded shunt; current therapy is endoscopic sclerosis.

Four makeshift shunts were constructed using large but variceal vessels, all of which thrombosed. These patients are being managed currently by sclerotherapy.

Central splenorenal shunt with incapacitating encephalopathy: closure of shunt. The patient had a central splenorenal shunt performed at age 21 years, developed hyperammonemia 15 years later, followed by progressive hepatic encephalopathy. When first seen at Emory (age 42 years), there was overt and severe symptomatology despite a rigorous antiencephalopathy regimen. Blood ammonia level after a meal with 20 g of protein exceeded 500 µg/dl. The patient was totally incapacitated. A decision was made to close the shunt and manage future bleeding, if necessary, with sclerotherapy. After closure of the shunt, clinical and laboratory abnormalities began to clear rapidly. Within a short time she could tolerate a normal protein diet. Of equal significance was the return to normal of the EEG, memory, and other aspects of CNS function, demonstrating the reversibility, by restoration of portal perfusion, of a most severe encephalopathy sustained for a period of years.

Five years later, having enjoyed excellent health and return to all her normal activities, variceal bleeding recurred. Endoscopic sclerotherapy was offered in her home city; she and her family elected to return to Emory. While awaiting urgent air transportation to the United States and Atlanta, the patient sustained an exsanguinating hemorrhage and died.

Non-shunt Operations

Before the rediscovery of endoscopic sclerotherapy, nonshunt procedures such as splenectomy and gastric devascularization were often used in patients for whom no shunt was possible or had been attempted and failed. Twenty patients fall into this category, 12 of whom had the spleen *in situ* at the time of operation at Emory. This group has not fared well with rebleeding occurring in more than 50%, a mortality rate of 25%, and an additional four patients were lost to follow-up. The severity of mortality and morbidity raise the question of the appropriateness of procedures using splenectomy without a shunt for patients with PVT.

Simple devascularization of the stomach may be useful, on occasion, essentially to improve effectiveness of long-term endoscopic sclerotherapy. There was one spectacular success in the devascularization group,

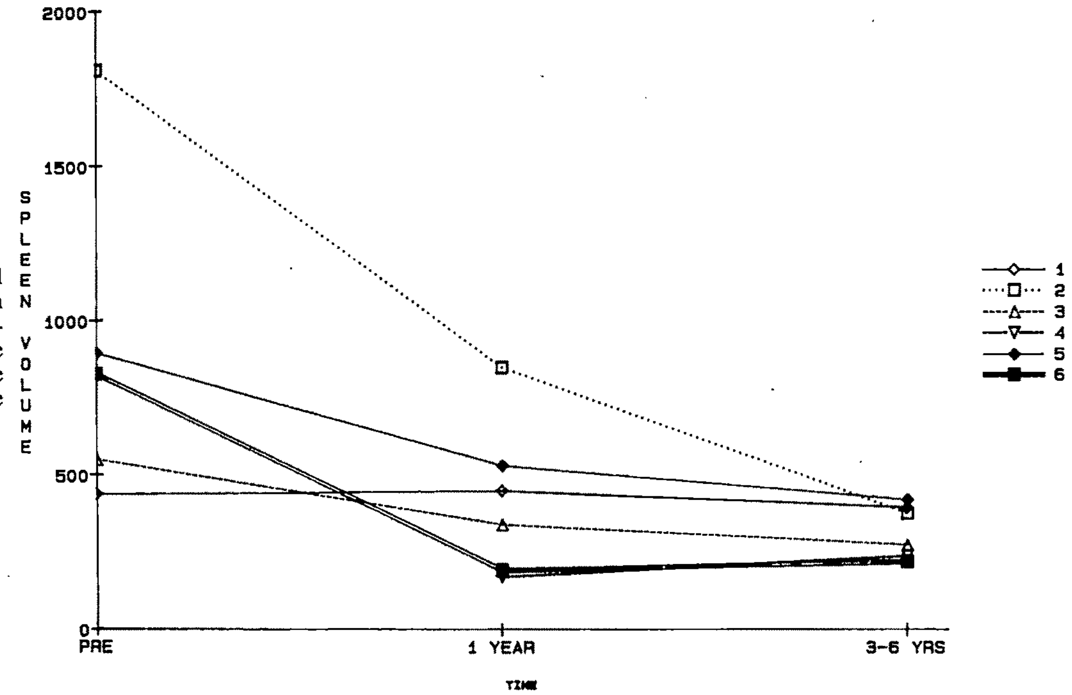

FIG. 7. The individual changes in spleen volume in the 6 patients studied in detail after DSRS. The changes from preoperative to 1 year and 3-6 years are statistically significant.

which highlights a principle and emphasizes an exception to the rule. The patient was referred with massive gastrointestinal (GI) bleeding that was emanating from below the duodenum. This man had sustained a common bile duct injury for which a Roux-en-Y loop of jejunum was used in the repair. With the occurrence of hemorrhage, an angiogram was obtained that disclosed PVT and a large collateral from the susperior mesenteric vein to the area of the hilus of the liver. At operation the Roux loop was greatly distended with blood. The bowel was opened near the biliary–enteric anastomosis and torrential bleeding was coming from varices passing from the jejunal loop into and up the common bile duct. A ligature of the jejunal branch of the superior mesen-

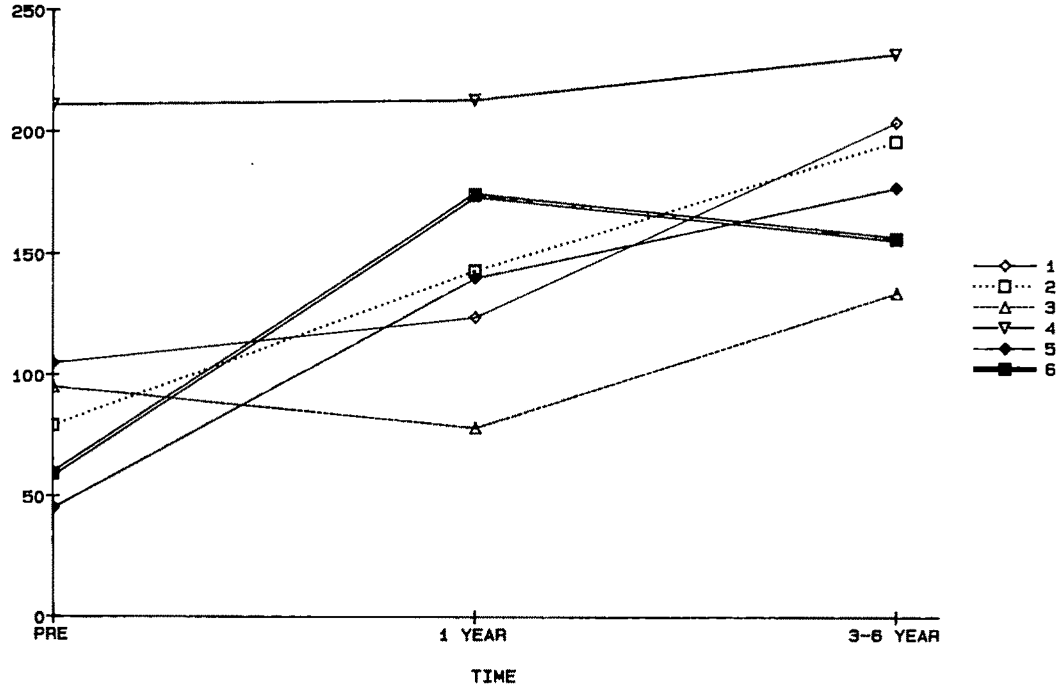

FIG. 8. The individual changes in platelet counts in the six patients serially studied after DSRS. Note the initial thrombocytopenia in 5, and the continuing and significant improvement.

TABLE 6. *Outcome for Patients with no Patent Major Portal Vein Tributary at Time of Referral*

Management	No. of Patients	Rebleeding	Deaths

Devascularization/sclerosis	10	5	3
Sclerosis	12	4	0
Makeshift shunt	4	3	0

teric vein at its base in the mesentery caused immediate cessation of bleeding.

The principle of hepatopetal collaterals in PVT is demonstrated clearly by this patient, and secondly illustrates the need to be aware of unusual sources of bleeding into the GI tract. Another instance of the Roux-en-Y–PVT connection has been reported by the Emory Faculty from Grady Hospital.[21] A Roux-en-Y loop provides a major conduit for inflow into the collateral veins perfusing the liver.

Endoscopic Sclerotherapy (EVS)

EVS has become the initial form of therapy for bleeding esophageal varices in the cirrhotic patient in many centers. In PVT, however, the pathophysiology of the process is different and hard data as to outcome are scarce. One of our concerns has been the danger of leading to further phlebitis and/or thrombosis of the major venous tributaries that could be used for a selective shunt. However, based on long-term studies of other therapies in PVT, we believe it is too early to take a firm position as to the proper role of EVS and PVT patients. There are no good data with long-term follow-up to answer the questions of rebleeding rate, extension of thrombosis, and other forms of morbidity and mortality of which we are aware. Repeated studies have small numbers with limited follow-up.[14-17] In the Emory series, 29 patients have had sclerotherapy for long-term management. Twelve (41%) have had EVS begun here after splenectomy elsewhere or having no patent major tributaries of the portal system. The remaining 17 followed operation here, including six unsuccessful shunts (1 DSRS, 4 makeshift, 1 mesocaval).

The first patient with PVT sclerosed at Emory was in 1978 and has a 9-year follow-up; the mean duration of follow-up is 50 months. Rebleeding has occurred thus far in eight patients (28%), but there has been no mortality. Morbidity has included one patient with aspiration pneumonia and two patients with long-term neurological sequelae in whom cause and effect has not been clearly shown. Although the precise role of EVS remains to be defined, it has already proven to be a valuable addition to the therapeutic armamentarium.

Discussion

There remain several areas of debate regarding the proper role of various diagnostic and therapeutic modalities in patients with PVT who have experienced GI bleeding. The issues range from the natural history of the disease, if left untreated, to results and complications of standard operative procedures, to new and promising forms of nonoperative interventional therapy.

Natural History

This study cannot assess this issue as all patients were referred by other physicians. There is no primary pediatric or family practice program at the Emory Hospital and consequently we rarely see patients with asymptomatic PVT.

Results of Operative Therapy for Bleeding Varices

In this aspect of the disease the Emory program has been quite active. Since 1971, the year our ongoing program for the study of portal hypertension was begun, we have seen 70 patients with PVT and a history of bleeding varices or other symptoms. Over half of our patients had had one or more operative attempts at control of varices before first being seen at Emory. This patient population (those with prior operation) has led to heightened understanding of two fundamental issues. First is the poor long-term results achieved in patients in whom no major tributary of the portal system was patent, and second, the predominant role splenectomy has played in producing this unhappy result. Table 6 shows the disheartening figures for those patients with no patent vessel for possible shunt; the poor results for long-term control of bleeding probably carry over into the sclerotherapy group as well. Although we do not have good data on the patency of the portal system before splenectomy in other hospitals, some insight can be obtained by comparing the success of shunt operations at Emory in patients with the spleen present *versus* those in whom it had been excised. After the initiation of the selective shunt policy at Emory, we have seen 30 patients in whom the spleen was present at operation and a shunt was possible in 25 (83%). In stark contrast is the 3 of 37 (8%) success rate for those with any prior operation and the 2 of 24 (8%), which followed simple splenectomy. Our dismay at these figures is intensified by the realization that many of the splenectomies were done solely to relieve the thrombocytopenia of hypersplenism.

Patency of Shunts

Long-term patency of shunts in patients with PVT is considered a rarity by some authors, but was clearly achieved in this study. Of the 25 patients whose vessel status permitted construction of a selective shunt, 24 (96%) had patent shunts proven by angiography before discharge. One patient had a minor revision of a kinked but open shunt; the sole occlusion was in a splenocaval anastomosis. The first DSRS patient is now 10 years post-shunt and has a patent shunt.

Because of the phlebitis present in many of the veins used for shunting, early reassessment has been carried out. In six of the 24 patent selective shunts, nonoperative dilatation was required for stenosis at the 3- or 6-month evaluation. One gastroepiploic anastomosis failed dilatation and required revision of the anastomosis at 1 year.

All of our four makeshift shunts in this series have occluded, four of five central splenorenal shunts done before referral to us had occluded, and one of two mesocaval shunts (an interposition graft) occluded. These results certainly are influenced by the nature of the phlebitic veins often encountered and the altered anatomy between tributaries must also be important. A central splenorenal shunt when the superior mesenteric and portal veins are thrombosed and the spleen is excised as part of the operative technique would certainly carry a high risk of failure! The DSRS maintains the high volume splenic flow as well as the collateral flow; this is undoubtedly a major factor in the excellent patency rates demonstrated by this study.

Control of Bleeding

Again, the selective shunts have been excellent in this regard. There has been a single long-term rebleed, in a patient with a stenosed gastroepiploic–renal shunt. There were two early postoperative bleeding episodes, a feature of selective shunts where transplenic decompression may require several weeks for maximum pressure reduction. Such bleeding is common before leaving the hospital; subsequent rebleeding has not occurred in either patient.

Nonshunting operations are performed widely in countries with portal hypertension secondary to schistosomiasis, hepatic fibrosis, and nonalcoholic cirrhosis, but numerous authors have cited the many dangers of splenectomy in the PVT patient.[4,9,12] The functional anatomy of the portal system is radically altered by the thrombotic process and splenectomy can accentuate this dysfunction. This may take many forms, such as thrombocytosis, venous infarction of the bowel, increased susceptibility to infection, loss of opportunity for a selective shunt, or by simply increasing the likelihood of esophagogastric bleeding by removal of low risk collaterals. As one reviews these patients and the analysis of experts in the field of PVT, the negative impact of splenectomy (with or without gastric devascularization) appears undeniable. There are no controlled trials of this question and there should be none with the possible exception of patients with an intact spleen but occluded splenic vein who have failed sclerotherapy.

Encephalopathy

The question of portasystemic encephalopathy in PVT, with or without shunts, continues to stimulate workers in this field.[22–24] There have been a number of reports indicating the problem to be significant[1,22,23] and others that fail to find real encephalopathy in any of their patients.[8,24]

The patient re-reported here is undeniable evidence that the syndrome of nitrogen-dependent encephalopathy in its severest form can occur after a total shunt in a patient with PVT. The question now is how often does this occur and should it enter into the decision as to optimal therapy for individual patients. There are insufficient data at this time to make a definitive statement. For accurate assessment of this question, studies are needed related to the pathophysiology of the encephalophy itself and two additional prerequisites. First is the long-term study of such patients (15–25 years) and second is the demonstration of a patent shunt at the time of restudy. Some recent studies from France illustrate these points.[24] Although only minor abnormalities were reported in those patients, it should be noted that the mean interval after operation was less than 5 years, and shunt patency was not documented. Crucial to this field will be long-term studies with clear demonstration of shunt and portal perfusion data at the time of the late assessment.

In our data on the selective shunt approach we have shown patent shunts and low rebleeding rates, sustained portal perfusion of the liver, and lack of encephalopathy; however, the time frame is too short (longest follow-up 10 years) for a definitive conclusion.

Sclerotherapy

An assessment of this new therapy is difficult at this time. There is little doubt that EVS is a major therapeutic modality for control of variceal bleeding, and the only question being when it should be used. The rebleeding rate for this group has not yet been determined. Rebleeding in the Emory patients has occurred eight times (28%), but this includes a large number of patients who had had previous operation which proved to be unsuccessful. The results of sclerotherapy as the first intervention has not been firmly established, in part because of the relatively recent return to this therapeutic modality. Small series[15–17] or incomplete[14] and limited follow-up leave this question open. A concern at our institution is the possibility of the sclerotherapy leading to occlusion of veins that could be used for a definitive shunt. Although there have been anecdotal reports of thrombus propagating to the intra-abdominal vessels, a true evaluation of this risk has not been accomplished. Sclerotherapy for varices in cirrhosis, chronic active hepatitis, and hepatic fibrosis has yielded good results at Emory; extension of this judgment to the PVT patients would be premature.

Miscellaneous Aspects of Interest

Eleven of the 25 DSRS patients are women in the childbearing age and thus far three have become pregnant. All three had uneventful deliveries of normal babies. With similar results from other centers there should be little concern about childbearing if such is desired by the patient.

Coagulopathy was not routinely studied but two patients are known to have an hypercoagulable syndrome. One has protein C deficiency and the other has an antithrombin III deficiency. PVT patients should be studied routinely for problems related to hypercoagulability and long-term anticoagulant therapy used when indicated.

The Roux loop anastomosed to the common bile duct provided graphic demonstration of the volume of portal flow which can perfuse the liver around a thrombosed portal vein. This phenomenon is not seen in portal sclerosis (ideopathic portal hypertension), another condition in which a normal liver biopsy and normal liver function are common. The venous pathology in portal sclerosis is so peripheral that no venous pathway can bypass the obstruction. In that regard portal sclerosis resembles schistosomiasis; there are hepatofugal collaterals, but no hepatopetal portal collateralization. Simple cholecystectomy in a PVT patient can be a vivid experience because of the collateral flow through and around the gallbladder bed!

Recommendations

This experience has led us to evolve our current management as shown in Figure 1. The emphasis is on full evaluation to determine the optimum method to prevent further bleeding. In essence, if a patent splenic vein can be found, a DSRS is, we believe, optimum therapy. In those who have no vein suitable for selective variceal decompression, sclerotherapy probably offers the best alternative approach.

DISCUSSION

DR. JOSEF E. FISCHER (Cincinnati, Ohio): This excellent presentation is another logical step in the attempt of the Atlanta group to define the place of shunting in the therapy of these difficult patients. As they very well pointed out, the patient with extrahepatic portal block has a basically normal liver and, unlike the patient with cirrhosis, has a dual blood supply to the hepatic lobule, the anatomy of which is normal.

There is no better theoretical place than in the patient with extrahepatic portal block for the idea of dividing the left side and the right side of the portal circulation in order to sustain perfusion to the liver. Total perfusion to the liver is probably decreased because, as the fourth power of the radius and the collaterals tend to be small, flow varies; but, in fact, as they pointed out, hepatic resistance is normal.

I would like to ask three questions of the group. First, Dr. Warren and his group have for some time attempted to define portal blood flow and separate the components of hepatic artery and portal venous flow, and I wonder whether they have any data through which they have been able to estimate the respective contributions of the hepatic artery and what residual portal venous flow exists in this particular population.

The contribution of the portal venous flow probably has some long-term prognostic significance.

Secondly, I gather that you do not recommend prophylactic shunting in this group. Prophylactic shunts are generally thought not to be indicated in patients with large varices and who have not bled; but in view of the fact that these patients who have not bled represent a group of patients with relatively normal preserved flow, in a patient with hypersplenism that is symptomatic and worries the gastroenterologist, would you allow yourself to be talked into a prophylactic "distal splenorenal shunt"?

I have on a couple of occasions. I have not yet been sorry, and I wonder what your own experience has been.

The third question was partially answered, but if memory serves me correctly, in 1964, Thompson and Sherlock in the *Lancet*[1] reviewed a very extensive long-term experience with extrahepatic portal block, coining the term "premature aging of the liver"—a condition in which patients with extrahepatic portal block seem to show a terminal phase of their extrahepatic portal block that is indistinguishable from that of patients with cirrhosis; and these patients died of encephalopathy, hepatic failure, ascites, and jaundice, at the age of approximately 50 years.

The argument was used in that paper that long-term deprivation of the normal volume of portal flow was responsible for hepatic failure. Is there another patient population that you have not discussed in this paper, or are these patients not old enough to exhibit this hepatic failure, or do you simply not believe in the entire concept?

DR. JOAQUIN S. ALDRETE (Birmingham, Alabama): That is a very nice updating of an old problem by Drs. Henderson, Millikan, and Warren.

I think that, in some of these patients with extrahepatic portal vein thrombosis, an important etiological factor, in at least one group, is hypercoagulability, which can usually be documented before operation, when the platelet count is over 300,000.

It is important to note that most of these patients have not only thrombosis of the portal vein itself, but also have some intraluminal trabeculations that extend toward the splenic vein and superior mesenteric veins. These trabeculations are part of the intima and cannot be removed; thus, eventually they lead to thrombosis of these veins.

The patients who do not have this extensive involvement and in whom the splenic vein is clear are suitable for a distal splenorenal shunt. My first question to Dr. Henderson is: Did you study some of the coagulation parameters in these patients before operation?

Because these patients have relatively normal liver function and their ascites can be effectively treated, they can be well for a long period of time. You showed in your slide where you categorized the patients studied in groups, according to the therapy they received. There were seven patients that received no therapy, and theirs was the only group that didn't experience any rebleeding. Would you give us some more information on that group?

Dr. Henderson, you mentioned a patient that had a central splenorenal shunt and developed encephalopathy, and later on, you showed that there was flow through the portal vein. I am unclear. I thought that all these patients had thrombosis of the portal vein. Did this patient re-establish the flow through other collaterals communicating with the intrahepatic portal branches? We have seen this once or twice; nevertheless, would you clarify that for me?

This paper is very important because it categorizes the indications for operation in each one of the groups of patients with extrahepatic portal thrombosis.

DR. MARTIN A. ADSON (Rochester, Minnesota): This study is just elegant: the long observation of a carefully studied group of patients. I have a single question. This concerns a patient about 25 years old with a distal splenorenal shunt done about 10 years ago. He is doing very well, playing racquetball, going into postgraduate training. He has had splenic infarcts on two occasions. These were not incapacitating, but enough to worry me about what is going on. No obvious coagulopathy is evident.

Can the authors tell me what I should think about that patient? Can I do something to prevent further troubles along those lines?

DR. ROBERT ZEPPA (Miami, Florida): The authors are indeed to be congratulated on this study, since it is one of the largest surgical studies of portal vein thrombosis with which I am familiar, and because no other patients have been studied quite so effectively and thoroughly as this group.

We had a small experience with this particular problem, but in no way does it compare to the particular series that has been reported today.

I have just one question. Except in cirrhotic patients, our experience with spontaneous thrombosis of the portal vein and extrahepatic portal system is very, very limited.

Our experience with portal vein thrombosis has been almost totally restricted to those patients who have had a history of omphalitis at birth, or severe peritoneal sepsis, either during childhood or young adulthood, with complete thrombosis presumably from pyelophlebitis.

These patients, interestingly enough, have done fairly well after devascularization procedures where no shunt could be done. This is not to say that the devascularization procedures in our hands eliminates the varices. The varices are still there, but the bleeding rate has been strikingly low, which has surprised us no end; and so far very few of these patients have had to come to sclerotherapy.

I wonder if the authors would comment upon the etiology of the thrombosis in their series of patients.

DR. W. DEAN WARREN (Closing discussion): This is sort of a complex topic and not of interest to a lot of you here in the audience, but an understanding of this disease will help a fairly large number of patients.

Joe Fischer, a long-time worker in the field, has raised some very pertinent questions. The first regards the quantitation of portal flow. He always likes to use that question because he knows that I can't answer it, and it gives him a perverse sense of pleasure, as you can see by his laughter. We utilized a technique at one time measuring radionuclide fractions in which it was estimated that about 30 to 40% of normal portal flow reached the liver through the huge collaterals that are called "cavernous transformation" by angiographers.

We do not advocate prophylactic shunt in these patients, but like you, have on a couple of occasions yielded to pressure from patients who live far from Atlanta, have a huge spleen, a platelet count of 50,000, and a white count of 1800; the doctor says, basically, "Well, I will just have to get his spleen taken out up here." We then say, "All right, it is better to do the shunt." A shunt takes care of the splenomegaly and hypersplenism; we don't advocate prophylactic shunt, and do it only when we are locked in.

Sheila Sherlock has mentioned this hepatic failure or fatigue syndrome that comes on after many years. I don't think it is explainable from our data. It seems to occur in about 10% of patients. You always wonder about viremias from the many, many transfusions these patients have had. The adult population with which we deal usually has had many transfusions; one patient had over 200 units of blood transfused prior to her shunt. We simply can't predict what will happen farther down the line, but we will be following these patients very closely. Dr. Fischer, yours is a very good question.

Dr. Aldrete, we do study these patients for hypercoagulability, and this is another good question. We have never seen the thrombocytosis to which you refer preop, except when there has been a splenectomy. If there is hypersplenism with thrombocytopenia and you take the spleen out, then there will be thrombocytosis in a certain number of patients, and we have had one patient in whom it then proceeded to cause coagulation of the entire portal system. It is a real problem.

We have also found deficiencies in protein C and protein S, which can give a diffuse hypercoagulability; unless the patients have bled, we have not operated on such patients, because they are a fairly marked increased risk. In that group of patients who have not had an operation and undergone sclerotherapy, careful long-term follow-up is very important. They are going to continue to be subject to bleeding, because their stomach will have sustained portal hypertensive pressure.

In terms of flow, PVT is a very important subset. Those big collaterals that Dr. Henderson showed in his slides are not hepatofugal collaterals. They are hepatopetal collaterals, carrying portal blood to the liver; this is what differentiates this condition from cirrhosis. In PVT, the liver has a normal sinusoidal pressure, as does the spleen after shunt. The collaterals go to the liver, therefore, as well as the spleen. In post-shunt cirrhosis there is high pressure in the liver and low pressure in the spleen, this gradient tends to push portal flow toward the spleen over the course of the years, and that is an important differential for the long-term well-being of these patients.

Dr. Adson has had a large experience in this field. As to the patient that he presents with the intrasplenic infarct, I have no experience. Some of these people do have a definable coagulopathy; I think I would get a hematological consult to see if there isn't a syndrome in which portal vein thrombosis might be a component of a larger problem of a hematologic nature.

Dr. Zeppa, my old-time friend and colleague, mentioned omphalitis and sepsis. We can identify such patients less often because ours are almost all adults. We don't see the children that you and others with children's hospitals do, but Sherlock estimated that about a third of them could be proven to come from one of those two causes. The new syndromes of the coagulation abnormalities are going to account for some more. We don't do quite the blue stomach devascularization of Zeppa and Womack and Johnson, but rely more heavily on a sort of devascularization, and then follow that with sclerotherapy.

Biliary Secretory IgA Levels in Rats with Protein–Calorie Malnutrition

GREGORY M. LIM, B.S.,* GEORGE F. SHELDON, M.D.,† and JOHN ALVERDY, M.D.

Malnutrition is a recognized cause of failure of host defense mechanisms. In the past 5 years, it has been demonstrated that the gut, long known to have significant morphologic changes with protein calorie malnutrition (PCM), is an immune organ affected by malnutrition. To assess the role of biliary immunoglobulin A (S-IgA), part of the barrier to bacterial invasion from the gastrointestinal tract, the following study was performed. Seventy-eight Fisher female inbred rats weighing 110–130 g were randomly separated into two groups. The control rats were fed standard rat chow. The experimental rats were fed a 2% agar protein depletion (PCM) diet (USP XV). The biliary tract of the rat was cannulated with Silastic tubing and bile flow and rat secretory immunoglobulin A (S-IgA) was sampled at intervals. S-IgA was measured by the Elisa method. Total bile protein was measured by micro-Kjeldahl. Bile was collected from the rats on day 0, 7, 14, 21, 29, 36, 42, and 49. During the study, the weight of rats fed the PCM diet decreased from 127.4 ± 14.5 g at day 0 to 83 ± 2.6 g on day 37. Control rats gained weight from 124.4 ± 14.5 g at day 0 to 153.6 ± 3.8 g at day 37. Total biliary protein at day 0 was 2.52 ± .05 mg/ml and at day 36 was 2.51 ± 11 mg/ml for PCM rats and 2.57 ± 10 mg/ml for control rats. Normal rats and control rats both had an initial increase of S-IgA from 2.74 ± 73 mg/ml on day 0 to 5.75 ± 1.75 mg/ml on day 37. Both PCM and control rats demonstrated an increase in S-IgA levels despite significant loss of weight in the experimental group. Similarly, total biliary protein was not decreased in either group. The results suggest that gut immune system is preserved despite significant protein calorie malnutrition.

From the Department of Surgery (Medical student), University of California, San Francisco, California, and Department of Surgery,† University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, North Carolina*

INFECTIONS ARE STILL THE MAJOR CAUSE of morbidity and mortality in our society.[1] Most of these infections occur after initial exposure of foreign proteins, bacteria, or viruses to mucous membranes. In response to the continual threat of infection, the body has developed an efficient host immune defense system concentrated in the mucous membranes. In the intestinal tract, because of the continous exposure to microbes and food antigens, it has been estimated that there are about 7.5 (10^{10}) anti-body-producing cells lining the mucosa of the gastrointestinal tract. Heremans calculated that this represents approximately 50 g of immunoglobulin-producing cells in the gut, which is comparable to the mass of the immunoglobulin-producing cells in the spleen.[1]

Although immunoglobulin A (IgA) had been observed as a precipitate in immunoelectrophoresis of human serum,[1] its purification allowed its role to be defined. IgA was also found to be the predominate immunoglobulin in human milk and human saliva as well as in many other secretions.[2] Tomasi demonstrated that secretory IgA was a dimer of IgA molecules with an additional polypeptide chain, the secretory component (SC).[3] It was later discovered that S-IgA also contained another polypeptide structure called the J-chain. The J-chain adds to the compact structure of S-IgA, and thus S-IgA antibodies are more resistant to enzymatic action than are serum IgA antibodies.

IgA with the J-chain is produced by specialized lymphoid cells (B-cells). It is then linked to SC on the surface of specialized epithelial cells (M-cells).[1] According to Brandtzaeg, the binding of Sc to the IgA dimer requires the presence of the J-chain.[4] After the binding of the IgA dimer to the SC polypeptide, the complex is transported through the epithelial cell and is then released at the apical surface of the cell. Thus, S-IgA is found in secretions like milk, saliva, tears, bile, as well as in fluids of the nasal, bronchial, intestinal, and genitourinary surfaces. The levels of IgA are indirectly regulated by the amount of exposure of foreign antigen.

Presented at the 100th Anniversary Meeting of The Southern Surgical Association; Hot Springs; Virginia; December 6–9, 1987.

Reprint requests: George F. Sheldon, M.D., Professor and Chairman, Department of Surgery, University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC 27599.

Submitted for publication: December 10, 1987.

According to Walker and Isselbacher, diminished levels of S-IgA may be related to mucosal atrophy.[5] Patients with S-IgA deficiency have an increased incidence of circulating antibodies to food and bacterial antigens, which suggests an increased permeability of the mucosal barrier. Patients with protein–calorie malnutrition may have an increased incidence of intestinal infections, circulating antibodies to food and bacteria, and higher incidence of autoimmune disease.

Malnutrition affects the humoral immune system in many ways. The B lymphocyte subpopulations and immunoglobulin synthesis of serum IgG, IgM, and IgA are usually normal or increased; however, secretory IgA (S-IgA) levels in the respiratory and gastrointestinal fluids are generally decreased as are secretory IgA antibody responses.[6]

Secretory IgA binds and neutralizes viruses and bacterial enterotoxins, S-IgA agglutinates bacteria and prevents the attachment of bacteria to epithelial cells. However, the bacteriolytic action of S-IgA antibodies *via* lysozyme and the complement system has been verified by some investigations and not by others. Successful immunization for poliomyelitis involves the complex gut immune system. The polio virus (Sabin) oral immunization has led to a predominately IgA response in intestinal secretions, whereas parenteral immunization (Salk) did not cause elaboration of intestinal antibody.[7] The local immune response is dependent on route of administration (oral or parenteral) as well as the amount of antigens. Secretory IgA is the predominant antibody in bile. Polymeric IgA is transported into bile after the addition of the SC portion by the hepatic cells[1] and is a major source of intestinal S-IgA.

From previous work, it has been demonstrated that malnourished patients exhibit an increased susceptibility to infection, and thus, one might expect a decrease in the amount of S-IgA.[8] Protein–calorie malnutrition has a profound effect on the structure of the gastrointestinal (GI) tract. Moreover, atrophy of mucosal epothelium, Peyer's patches, and gut-associated lymphatic tissue (GALT) could diminish the cell numbers and function for maintaining GI immune function, specifically S-IgA.

Moreover, earlier studies have shown that route of nutrition (parenteral or enteral) influences gut morphology. Gut atrophy occurs when food is absent from the GI tract and is associated with increased susceptibility to infection.[9,10] Acknowledging that S-IgA is only one component of the complex GI immune system, these studies were done to determine if S-IgA was affected by malnutrition in rats. Because S-IgA is prominent in bile, the model used evaluates S-IgA in bile.

Materials and Methods

Seventy-eight female inbred Fisher rats weighing 110–130 g were randomly separated into two groups of 38 and 40. The control group included 38 rats, the test (PCM) group included 40 rats. The control rats were fed a standard rat chow diet and water *ad libitum*. The PCM rats were fed a 2% agar protein depletion diet (USP XV) and water *ad libitum*. This diet was selected as the test rats will lose a predictable amount of weight. Moreover, few rats will die because of malnutrition.

During the experimental period, five rats from each group were studied every 7 days. The rats were weighed and anesthetized intraperitoneally with sodium pentathol, 0.01 ml/100 g body weight (BW), and intramuscularly with ketamine, 0.01 ml/100 g BW. A celiotomy was performed and the common bile duct was cannulated with Silastic tubing (O.D. 0.025″, I.D. 0.012″). Bile was collected over a 30-minute period and the rats were killed.

The rat bile specimens were then measured and the bile flow rate was calculated. It is important to measure bile flow so that obstruction of the bile flow by cannulation can be avoided. The samples were stored in plastic vials at −20 C until the total protein and S-IgA assays were performed (Fig. 1).

Rat S-IgA used for standards in the assay was purified from rat bile courtesy of the Rosalind Russell Laboratory at the University of California–San Francisco. Standards were prepared by diluting rat S-IgA with 0.01 M PBS— 0.1% Tween 20 pH 7.4 at concentrations of 12.5–200 mg/ml on the day the assay was performed.

Immulon II 96-well microtitre plates (Dynatech Labs, Alexandria, VA) were coated with goat anti-rat S-IgA (1 μg/ml in 0.01 M PBS pH 7.4, 200 μl/well). The goat antisera was purchased from Miles Laboratories (Ames Division, Elkhart, IN) and purified. The purification of the antisera involved dialysis with 0.02 Tris-HCL. 0.028 M NaCl buffer pH 7.2, purification of the IgG fraction *via* affinity chromatography with DEAE Affigel blue (Bio Rad Labs, Rockville, NY), concentration with Lyphogel (Gelman Sciences, Inc., Ann Arbor, MI), dialysis with 0.01 M phosphate buffered saline (PBS) pH 7.4, and stored at 4 C in a borosilicate glass vial. The optical density at 280 mm of the antisera was used to calculate the protein concentration. Plates containing the goat anti-rat S-IgA were placed in a 37 C humid incubator for 1–2 hours, then stored at −20 C. Before being used, the plates were thawed and washed three times with PBS-Tween 20, allowing 2–3 minutes equilibrium time per wash, then drained and blotted. Bile samples were thawed and diluted 1:20,000 with PBS-Tween 20. Two hundred microliters per well of blank solution (PBS-Tween) was pipetted to the first two columns of a coated microtitre plate. To avoid the "edge effect," the edge rows were not used, and 200 μl/well of various concentrations of standard was pipetted into two rows of the plate. Adjacent wells were filled with 200 μl/well of PBS-Tween 20 and the remaining wells received diluted

TABLE 1. *Biliary Flow, IgA Values—Normal* Versus *Control*

* The malnutrition phase of the experiment was terminated at day 36. On day 37, five PCM rats were refed and samples during the refeeding made at day 42 and 49. Six PCM rats died between days 32 and 36.

bile, four replicas per sample. The plate was placed in a humid 37 C incubator for 1 hour, and then washed three times with PBS-Tween 20. Conjugated horseradish peroxidase-IgG (IgG specific for rat S-IgA) (Jackson Immunoresearch Labs, Inc., West Grove, PA) was diluted 1:5000 with PBS-Tween 20, then added to the plate, 200 µl/well. The plate was incubated 1 hour at 37 C and washed three times with PBS-Tween 20. During this interim, a horseradish peroxidase substrate solution was prepared using 0.04% o-phenylenediamine dihydrochloride and 0.04% of 30% H_2O_2 in a 0.1M citric acid 0.2 M Na_2HPO_4 buffer. After the plate was washed, 200 µl/well of substrate solution was added and the rection was allowed to proceed 15 minutes ± 2 seconds at room temperature. The reaction was stopped by the addition of 50 µl/well of 2.5 N H_2SO_4 and the optical density of each well was determined with a Multiskan microtitre plate reader blended with air using the 492 mm filter (Flow Laboratories, Inc., McLean, VA). Sample values were obtained by interpolation from linear regression of the standard curves. Total bile protein was measured by a colorimetric micro-Kjeldahl method (SIGMA bulletin 690).

Results

On day 0, 10 rats were operated on and their bile ducts were cannulated. Bile was collected for 30 minutes. The average flow of bile was 1.42 ± 0.59 ml/hr. The average total protein content of the bile collected was 2.52 ± 0.05 mg/ml, whereas the average concentration of S-IgA was 2.74 ± 0.73 mg/ml (Table 1).

The 2% agar diet used in many previous experiments produced a predictable weight loss with minimal malnutrition-related mortality.[8-10] The female Fisher rats in the control group weighed 124.4 ± 14.5 g at the beginning of the experiment. These rats fed a "normal" diet of rat chow gained weight, 29.1 ± 9.3 g. Rats fed a 2% agar protein depletion diet (USP XV) loss weight (44.4 g) to 83.0 ± 2.6 g during the experiments. The weight changes at the extreme of the experiment (36 days) are statistically significant ($p < 0.001$). Immune function such as survival from *Escherichia coli*-Hb peritonitis usually differs from control after 14 days of the 2% agar protein depletion diet.[7,9,10] The experiment represents an extreme nutritional challenge to the immune system.

On day 7, another two groups of five rats, one control and one PCM, were studied. The bile ducts were cannulated and bile was collected for 30 minutes. The control rats had an average flow rate of 1.54 ± 0.58 ml/hr, an average total protein content of 2.61 ± 0.10 mg/ml, and an S-IgA concentration of 1.68 ± 0.77 mg/ml. In the PCM rats, the average bile flow rate was 1.44 ± 0.49 ml/hr, an average total protein value was 2.4 ± 0.07 mg/ml, and an average S-IgA concentration was 1.95 ± 0.54 mg/ml.

On day 14, another five rats from each group were operated on and bile was collected. The control rats had an average flow rate of 1.62 ± 0.16 ml/hr, an average total protein value of 2.55 ± 0.05 mg/ml, and an S-IgA concentration of 2.46 ± 1.34 mg/ml. The PCM rats had an average flow rate of 1.56 ± 0.70 ml/hr, an average total protein value of 2.47 ± 0.10 mg/ml, and an average S-IgA concentration of 3.14 ± 0.91 mg/ml.

On day 21, another five rats from each group were operated on and bile was collected. The control rats had an average flow rate of 1.91 ± 0.29 ml/hr, an average total protein value of 2.44 ± 0.04 mg/ml, and an S-IgA concentration of 4.13 ± 0.40 mg/ml. The PCM rats had an average flow rate of 1.27 ± 0.40 ml/hr, an average total protein value of 2.32 ± 0.09 mg/ml, and an average S-IgA concentration of 3.90 ± 2.40 mg/ml.

On day 29, another five rats from each group were

TABLE 2. *Data Analysis: Day 36*

	PCM	Control	p value
Wt (g)	−44.4 ± 12	19 ± 10.7	<0.001
Total protein (bile) mg/ml	2.51 ± 11	2.57 ± 10	NS
S-IgA (mg/ml)	+3.01 ± 1.02	1.69 ± 63	NS

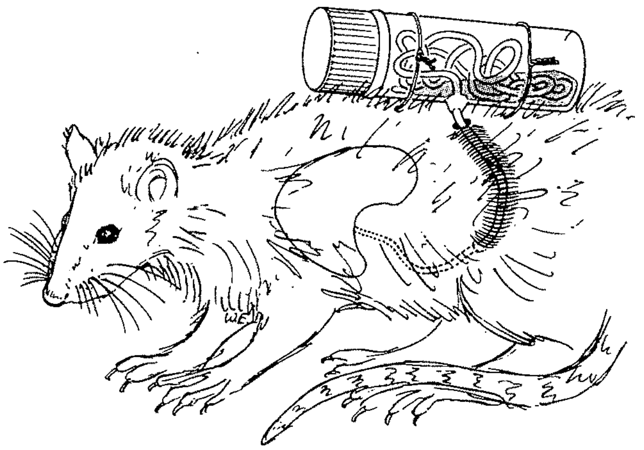

FIG. 1. Rat biliary sampling preparation.

operated on and bile was collected. The control rats had an average flow rate of 2.19 ± 0.88 ml/hr, and average total protein value of 2.52 ± 0.08 mg/ml, and an S-IgA concentration of 3.68 ± 1.24 mg/ml. The PCM rats had an average flow rate of 1.88 ± 0.52 ml/hr, an average total protein value of 2.30 ± 0.08 mg/ml, and an average S-IgA concentration of 4.21 ± 1.27 mg/ml.

On day 36, another five rats from each group were operated on and bile was collected. The control rats had an average flow rate of 3.06 ± 2.16 ml/hr, an average total protein value of 2.57 ± 0.10 mg/ml, and an S-IgA concentration of 5.44 ± 0.36 mg/ml. The PCM rats had an average flow rate of 1.86 ± 0.23 ml/hr, an average total protein value of 2.51 ± 0.11 mg/ml, and an average S-IgA concentration of 5.75 ± 1.75 mg/ml.

On day 37, five PCM rats were refed with standard rat chow and on day 42 bile was again collected. The five control rats had an average flow rate of 2.36 ± 0.96 ml/hr, an average total protein value of 2.57 ± 0.05 mg/ml, and an S-IgA concentration of 1.50 ± 0.43 mg/ml. The PCM rats had an average flow rate of 2.83 ± 1.04 ml/hr, an average total protein value of 2.50 ± 0.72 mg/ml, and an average S-IgA concentration of 2.19 ± 0.79 mg/ml.

On day 49, the experiment was terminated and samples of bile were collected from the rest of the rats. The control rats had an average flow rate of 2.59 ml/hr, an average total protein value of 2.53 ± 0.09 mg/ml, and an S-IgA concentration of 2.81 ± mg/ml. The PCM rats had an average flow rate of 3.25 ± 0.96 ml/hr, an average total protein value of 2.46 ± 0.06 mg/ml, and an average S-IgA concentration of 3.28 ± 1.38 mg/ml.

Statistical analysis, using 95% confidence interval, was established using a pooled t-test and the levels of IgA and total protein for the PCM and control rats were found to be statistically the same ($p < 0.05$). These results suggest that protein–calorie malnutrition minimally affects the levels of biliary IgA and protein, which did not significantly ($p < 0.05$) change during a 36-day period of a protein depletion diet (Table 2).

Discussion

One of the major defense mechanisms against bacterial and viral invasion through mucosal surfaces is from secretory immunoglobulins, *i.e.,* S-IgA and S-IgM, and secondarily, IgE, IgG, and IgD. Immunoglobulin A (IgA) is in secretions of the gastrointestinal and respiratory tracts as well as in milk and saliva.

The origin of IgA in the gastrointestinal tract appears to be from lymphoblastic cells of the gut-associated lymphoid tissue (GALT) which differentiates to precursor IgA producing plasma cells.[11,12] The plasma cells located in the lamina propria of the intestine are stimulated by intestinal antigens that "leak" or are transported by specialized membranous epithelial cells (M-cells) to produce S-IgA (dimeric form). In the presence of IgA deficiency, S-IgM will be increased as compensatory measure.

Secretory IgA differs from serum IgA in that IgA is bonded tightly to the J-chain and is secreted into the crypts of the mucosa. It is also linked to the secretory component (SC), which protects the molecule from proteolytic enzymatic action in the intestine.[13,14]

In the bile, approximately 60% of the IgA is in the S-IgA form. Serum IgA is transported into the hematocytes and is transformed into the polymeric form.[15,16] It is then secreted into the bile. In bile duct obstruction, S-IgA is increased in the serum. On relief of the obstruction, the level of S-IgA in the serum returns to normal levels.

The action of S-IgA is protective and binds with intestinal antigens. It neutralizes bacterial and viral enterotoxins along with agglutinization of the organisms. It also functions to prevent the attachment of bacteria to the surface epithelium. This function is important in infections such as Streptococcal pharyngitis or cholera. S-IgA does not seem to have any clearcut effect on the complement system, although bacteriolytic action *via* the complement system has been described.[17] Human serum antibody responses are variable and are probably due to the nature of the antigen, the amount involved, the age of the patient, and the route of infection.

Protein–calorie malnutrition (PCM) is associated with many immunologic defects. PCM causes an increased gastrointestinal permeability to antigenic factors. In severely malnourished children, a selective decrease in secretory IgA levels in intestinal secretions occurs. PCM is associated with an increased incidence of intestinal infection, circulating antibodies to food and bacterial antigens, and evidence of autoimmune disease. Paradoxically, some studies of children who have kwashiorkor reveal T-cell lymphokin levels—migration inhibition factor (MIF) and leukocyte migration inhibition factor (LMI), which are similar to normal children.[18] However, studies by Sirisinha et al. found S-IgA levels decreased in children who have PCM.[19]

Our study was undertaken to determine if the S-IgA levels of bile in rats were lowered by malnutrition. The weight of the Fisher rats in PCM and control rats was predictable. The weight of PCM rats decreased from an average weight of 127.4 ± 14.5 g at day 0 to 83 ± 2.6 g on day 37, whereas the control rats' weight increased from 124.4 ± 14.5 g on day 0 to 153.6 ± 3.8 g on day 37. The control rats, who were fed a normal diet, increased in weight and appeared healthy. The levels of S-IgA in PCM rats increased from 2.74 ± 0.73 mg/ml on day 0 to 5.75 ± 1.75 mg/ml on day 37, as did the control rats' S-IgA levels increase from 2.74 ± 0.73 mg/ml to 5.44 ± 0.36 mg/ml. Both the PCM and control rats' S-IgA levels similarly increased despite the PCM rats losing weight and the control rats gaining weight. These results suggest that the immune system of the gut may be of great importance and appears to be maintained, whereas other bodily systems deteriorate in the presence of malnutrition.

The total biliary protein level on day 0 was 2.52 ± 0.05 mg/ml and on day 36 was 2.51 ± 0.11 mg/ml for PCM rats and 2.57 ± 0.10 for the control rats. The total biliary protein levels remained constant in both the PCM and control rats. Even in the absence of sufficient protein, PCM rats maintained a constant biliary protein level. No differences occurred between the control rats and the PCM rats in terms of total protein and S-IgA concentrations in their bile.

Prior experiments of *E. coli*-Hb adjuvant peritonitis and other immune studies show that rats of this breed, age, and sex become highly susceptible to infection at 14 days. During 14–21 days of a 2% agar diet, weight loss is approximately 25% of starting weight. One to two weeks of the diet causes substantial loss of body protein and fat. The model results in pronounced loss of weight and protein in the small intestine as well.

It is surprising that IgA, the "antiseptic paint" of the gastrointestinal tract is maintained in severe malnutrition. It is especially surprising that IgA is well preserved in PCM because of the well-known atrophy of the small intestinal mucosa associated with malnutrition. Because the intestinal mucosa comes into greatest contact with foreign antigens, bacteria, and viruses, constant levels of S-IgA aid in maintenance of protection against ingested bacteria, viruses, and other antigens. It appears the biliary S-IgA is a protein of high biologic priority.

DISCUSSION

DR. GEORGE L. JORDAN, JR. (Houston, Texas): We are indebted to Drs. Sheldon and Lim for the information contained in this paper. Immunology has been a subject of interest to surgeons over a good many years now, but actually only a few surgeons are conducting serious experimental studies. The subject of secretory immunoglobulins is almost nonexistent in the surgical literature. In fact, I had a computer search of the recent literature and found only one other recent article, and that was by Dr. Sheldon and his group. That particular article showed that secretory IgA in the bile decreased in animals fed intravenously and that oral food intake was necessary in maintaining normal levels. This study shows that restricting protein in the diet did not reduce IgA secretion in the bile of animals in this experiment. These studies are obviously of great importance to the general surgeons, because the bacteria which enter through the gastrointestinal tract are the cause of intra-abdominal infections following gastrointestinal surgery in most cases. I don't pretend to be an expert in this area myself, but this study raises several questions.

1. Dr. Sheldon, do you believe that the decrease in IgA secretion of the bile in animals on intravenous feeding simply represents the lack of stimulation resulting from food, or is it a contributing factor to sepsis in the critically ill patient in our ICU's?
2. Studies by others have demonstrated that vitamin A deficiency does reduce secretory IgA in the bile. Did these animals have a normal vitamin intake during the time of their protein deprivation, and have you evaluated other dietary-restricted programs?
3. Other investigators believe that the rat is not the optimum experimental animal, and state that the spectrum of immunoglobulins in the bile of the rat is not just like that in the human, and that there are other animals, such as the dog, in which there is a greater similarity between the two. Have you done studies in other animals, and particularly, have you done studies on human bile—for example, in patients that have a T-tube in place for a prolonged period?
4. Do you believe that there are methods which might increase the concentration of secretory IgA?
5. Do you believe that the determination of IgA in human bile or other gastrointestinal secretions might allow selection of patients who need special protection from infection in the postoperative period?
6. Have you studied any other immunoglobulins in the bile or in other fluids in the gastrointestinal tract? It is my understanding that immunoglobulins other than IgA are present in human bile in significant concentrations as compared to IgA, in contradistinction to the rat.

DR. CAROL E. H. SCOTT-CONNER (Jackson, Mississippi): The importance of the gut as a component of host defense has long been recognized. The gut-associated lymphoid tissue is exposed to and processes a vast array of foreign antigens. Immunoglobulin A forms a crucial part of this defense against the translocation of intraluminal bacteria.

The experimental data presented by Dr. Sheldon nicely demonstrates that secretion of biliary IgA is not impaired in malnourished rats and underscores the teleological importance of this substance.

I would like to ask Dr. Sheldon to consider the role of IgA in the host defense impairment noted in extrahepatic biliary obstruction.

In mechanical biliary obstruction, biliary secretion of IgA is blocked, and intraluminal IgA levels may fall. This decrease in biliary secretory IgA might contribute to the profound suppression in reticuloendothelial and lymphocyte function noted in extrahepatic biliary obstruction.

There are experimental data to suggest that internal biliary drainage which restores the intrahepatic circulation mitigates many of the adverse effects noted in obstructive jaundice.

In contrast, external biliary drainage, while effective in decreasing the level of jaundice, does not. Restoration of intraluminal bile salts has been implicated as one possible mechanism. Increase in intraluminal biliary secretory IgA levels might be another.

I would like to ask whether you have looked at biliary secretory IgA levels in rats with mechanical biliary obstruction using your nice experimental preparation, and, in particular, if you have studied the effect of reversal of obstruction by internal biliary drainage as opposed to external biliary drainage.

DR. R. SCOTT JONES (Charlottesville, Virginia): This was an excellent experiment and an excellent presentation. I think the study was designed and analyzed critically.

Dr. Sheldon has introduced a concept of studying immunoproteins in bile that I think will stimulate further study.

I had an opportunity to read his manuscript and wanted to make one particular comment about his method of data analysis and the conclusion of his study. The principal information regarding the bile secretion in these rats that was presented included bile flow presented in mls per hour and IgA concentration in mgs per ml. And using those two parameters, he concluded that the secretion was similar in the experimental and control groups.

Another parameter of interest would be the total IgA secretion in these animals per unit time. In other words, if you multiply the volume of bile times the concentration of the immunoglobulin, you would then understand the total amount of IgA secreted per unit time, which may be a very important observation.

A very brief and rough calculation from the data would suggest to me that at the end of the period of starvation, if one did such a calculation, then the total output of IgA in the control animals would exceed the experimental approximately threefold. Whether that had statistical significance would certainly bear examination.

This is probably a very important mechanism, not only in biliary infections, but also the maintenance of the flora and minimizing of invasive infections in the G-I tract. I think this is truly creative work and extremely well done, and I want to compliment Dr. Sheldon and his colleagues on this important contribution.

DR. GEORGE F. SHELDON (Chapel Hill, North Carolina): I would like to thank the discussants for their kind comments. I especially appreciate Dr. Jones's, because I do think that this is new enough that we may not be looking at the parameters as we should. I am very grateful for that suggestion.

Dr. Scott-Conner, I appreciate your comments; we have not done any experiments with mechanical obstruction. Your suggestions and comments need to be examined. The obstructed bile duct is easy to produce. It may well be that IgA will be inactivated by obstruction, which may be what you are suggesting.

Dr. Jordan has raised all the questions. For most of them, I lack answers.

The decrease of IgA with I.V. feeding has shown that intraluminal presence of foodstuffs is necessary for IgA production.

(Slide) As to the type of diet, it is a standard diet made by USP and is called "2% Agar Protein Depletion Diet." It has a lot of vitamin A.

As animals and people become malnourished, the kinetics of interaction among vitamins and trace elements become complicated. What are sufficient quantities of vitamins and trace metals at one point in time may be insufficient later.

Are there methods to increase IgA? You probably could with some antigenic stimuli that could be ingested.

The question about other immunoglobulins is a good one. In this model, as shown by a French investigator, 90% of the immunoglobulin in this type of animal is IgA, so it is valid for this experiment. Whether it is valid in all instances in unknown. Patients with congenital absence of IgA and other dysgammaglobulinemias do not have a high incidence of intestinal infections. They have low IgA, but the other immunoglobulins are elevated.

Again, I would like to thank everyone for their comments. I would like to thank the Association for the privilege of membership and Dr. David Saviston, Dr. Richard Meyer, and Dr. Colin Thomas for their sponsorship for membership.

Notice to Contributors and Subscribers

ANNALS OF SURGERY is a monthly journal which considers for publication original articles in the field of surgery. It is the oldest continuously published journal in the English language solely devoted to the surgical sciences. The Editorial Board considers only papers judged to offer significant contributions to the advancement of surgical knowledge.

CONTRIBUTIONS. Four typed copies of the manuscript and four copies of the illustrations should be sent prepaid to the Chairman of the Editorial Board of Annals of Surgery.

David C. Sabiston, Jr., M.D.
Annals of Surgery
Department of Surgery
Duke University Medical Center
Durham, North Carolina 27710

Annals of Surgery has joined a number of other leading Medical Journals which endorse the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals." These Requirements were established by an agreement among a number of Editors of Clinical Journals in the United States, Canada and the United Kingdom. The Criteria for preparation of manuscripts are as follows:

SUMMARY OF REQUIREMENTS

Type manuscript double spaced, including title page, abstract, text, acknowledgments, references, tables, and legends.

Each manuscript component should begin on a new page, in this sequence:

Title page
Abstract and key words
Text
Acknowledgments
References
Tables: each table, complete with title and footnotes, on a separate page
Legends for illustrations

Illustrations must be good quality, unmounted glossy prints usually 12.7 by 17.3 cm (5 by 7 in.) but no larger than 20.3 by 25.4 cm (8 by 10 in.).

Submit the required number of copies of manuscript and figures (*see* journal's instructions) in heavy-paper envelope. Submitted manuscript should be accompanied by covering letter, as described under "Submission of Manuscripts," and permissions to reproduce previously published materials or to use illustrations that may identify subjects.

Follow journal's instructions for transfer of copyright.

Authors should keep copies of everything submitted.

PREPARATION OF MANUSCRIPT

Type manuscript on white bond paper, 20.3 by 26.7 cm or 21.6 by 27.9 cm (8 by 10½ in. or 8½ by 11 in.) or ISO A4 (212 by 297 mm) with margins of at least 2.5 cm (1 in.). Use double spacing throughout, including title page, abstract, text, acknowledgments, references, tables, and legends for illustrations. Begin each of the following sections on separate pages: title page, abstract and key words, text, acknowledgments, references, individual tables, and legends. Number pages consecutively, beginning with the title page. Type the page number in the upper right-hand corner of each page.

Manuscripts will be reviewed for possible publication with the understanding that they are being submitted to one journal at a time and have not been published, simultaneously submitted, or already accepted for publication elsewhere. This does not preclude consideration of a manuscript that has been rejected by another journal or of a complete report that follows publication of preliminary findings elsewhere, usually in the form of an abstract. Copies of any possibly duplicative published material should be submitted with the manuscript that is being sent for consideration.

TITLE PAGE

The title page should contain [1] the title of the article, which should be concise but informative; [2] a short running head or footline of no more than 40 characters (count letters and spaces) placed at the foot of the title page and identified; [3] first name, middle initial, and last name of each author, with highest academic degree(s); [4] name of department(s) and institution(s) to which the work should be attributed; [5] disclaimers, if any; [6] name and address of author responsible for correspondence about the manuscript; [7] name and address of author to whom requests for reprints should be addressed, or statement that reprints will not be available from the author; [8] the source(s) of support in the form of grants, equipment, drugs, or all of these.

ABSTRACT AND KEY WORDS

The second page should carry an abstract of not more than 150 words. The abstract should state the purposes of the study or investigation, basic procedures (study subjects or experimental animals and observational and analytic methods), main findings (give specific data and their statistical significance, if possible), and the principal conclusions. Emphasize new and important aspects of the study or observations. Use only approved abbreviations (*see* list of Commonly Used Approved Abbreviations elsewhere in this document).

Key (indexing) terms: Below the abstract, provide and identify as such, three to 10 key words or short phrases that will assist indexers in cross-indexing your article and that may be published with the abstract. Use terms from the Medical Subject Headings list from *Index Medicus* whenever possible.

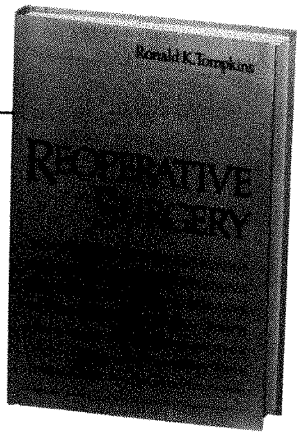
TEXT

The text of observational and experimental articles is usually—but not necessarily—divided into sections with the headings Introduction, Methods, Results, and Discussion. Long articles may need subheadings within some sections to clarify their content, especially the Results and Discussion sections. Other types of articles such as case reports, reviews, and editorials are likely to need other formats, and authors should consult individual journals for further guidance.

Introduction: Clearly state the *purpose* of the article. Summarize the rationale for the study or observation. Give only strictly pertinent references, and do not review the subject extensively.

Support for your **most** difficult decision

REOPERATIVE SURGERY



Edited by RONALD K. TOMPKINS, M.D., F.A.C.S.
With 27 Contributors

A wise and experienced surgeon has said, "The second most difficult decision to make in surgery is when to operate. The most difficult decision is when to re-operate." *—from the Preface*

When complications follow surgery...

Given the extensive, ever-expanding scope and complexity of many contemporary surgical procedures, postoperative complications have become a subject of increasing interest and significance. Many books on special aspects of surgery touch on the subject of complications, pitfalls, and alternative approaches, but this is the *first* to deal directly with reoperative surgery itself.

...experts can help...

This book is a multi-authored work which brings the experience of expert surgeons to bear on the difficult problems of reoperation in surgical patients. The surgical patient who requires another operation presents a singular challenge and set of problems to the surgeon which are not presented by the patient having his or her initial operation. A major feature of this work is the thoroughness of its coverage of the significant complications that follow general surgical procedures. Emphasis is placed on alternative approaches regarded as appropriate in the management of these complications. The use of specific case examples selected from the authors' personal experiences provide convincing evidence of the proper course of recommended action.

...with authoritative, personalized advice

Authors are all recognized experts who provide authoritative commentaries on surgical complications and their management. Each chapter is, therefore, highly personalized. Chapters cover general principles of reoperative surgery, anesthetic considerations, and separate coverage of most common general surgical procedures: the esophagus, the gastric system, inflammatory bowel disease, the liver, portal hypertension, biliary tract, pancreas, hernia, abdominal trauma, intra-abdominal infection, arterial surgery, cancer, anorectal surgery, the endocrine system, and surgery in children.

About 560 Pages. 208 Illustrations. 1988. $65.00.

Journal of Surgical Research

Clinical and Laboratory Investigation

Editor
Christopher K. Zarins, University of Chicago, Illinois
Associate Editors
Bruce L. Gewertz, University of Chicago, Illinois
Charles L. Rice, University of Washington, Seattle

Concerned with Clinical and Laboratory Investigations Relevant to Surgical Practice and Teaching

The *Journal of Surgical Research* emphasizes reports of clinical investigations or fundamental research bearing directly on surgical management that will be of general interest to a broad range of surgeons and surgical researchers. The articles presented need not have been the products of surgeons or surgical laboratories.

Features

Review articles and special articles relating to educational, research, or social issues of interest to the academic surgical community.

Official Organ of the Association for Academic Surgery

Volumes 44–45 (1988), 12 issues ISSN 0022-4804
In the U.S.A. and Canada: $230.00 All other countries: $281.00

Sample copies and privileged personal rates are available upon request.

Start anorectal therapy off on the right foot

Effective anorectal therapy begins with ANUSOL®. Offering prompt relief of pain, burning, and itching, ANUSOL allows anorectal patients to continue an active life-style. The rapid anesthetic action of pramoxine hydrochloride—available in ointment form—is as potent as benzocaine, but well tolerated and less sensitizing. And both ointment and suppository forms offer astringent and protectant properties to soothe irritated anorectal tissue.

To help put an end to anorectal discomfort, start your patients on the leading therapeutic choice for anorectal relief…recommend ANUSOL.

To receive a complimentary supply of patient booklets on anorectal care, along with an easel display, call 1-800-537-5179.

Anusol® Hemorrhoidal Suppositories and Ointment

helps anorectal patients stay active

In intra-abdominal and gynecologic infection due to indicated organisms

CEFOTAN® IM/IV (cefotetan disodium)

Does so much for so much less than cefoxitin

For Intravenous or Intramuscular Use
BRIEF SUMMARY

INDICATIONS AND USAGE

TREATMENT: CEFOTAN® (cefotetan disodium) is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary tract infections caused by *E coli*, *Klebsiella* species (including *K pneumoniae*), *Proteus mirabilis* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris*, *Providencia rettgeri*, and *Morganella morganii*).

Lower respiratory tract infections caused by *Streptococcus pneumoniae* (formerly *D pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K pneumoniae*), and *E coli*.

Skin and skin structure infections caused by *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis*,* *Streptococcus pyogenes* and *Streptococcus* species (excluding enterococci), and *E coli*.

Gynecologic infections caused by *Staphylococcus aureus*† (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis*,* *Streptococcus* species (excluding enterococci), *E coli*, *Proteus mirabilis*, *Neisseria gonorrhoeae*, *Bacteroides* species (excluding *B distasonis*, *B ovatus*, *B thetaiotaomicron*), *Fusobacterium* species,† and gram-positive anaerobic cocci (including *Peptococcus* and *Peptostreptococcus* species†).

Intra-abdominal infections caused by *E coli*, *Klebsiella* species (including *K pneumoniae*†), *Streptococcus* species (excluding enterococci), and *Bacteroides* species (excluding *B distasonis*, *B ovatus*, *B thetaiotaomicron*).

Bone and joint infections caused by *Staphylococcus aureus*.†

***NOTE:** Some strains of *Staphylococcus epidermidis* are resistant to cefotetan.

† Efficacy for this organism in this organ system was studied in fewer than ten infections.

PROPHYLAXIS: The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (eg, cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

Before therapy with CEFOTAN is instituted, careful inquiry should be made to determine whether the patient has had previous hypersensitivity reactions to cefotetan disodium, cephalosporins, penicillins, or other drugs. This product should be given cautiously to penicillin-sensitive patients. Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs. If an allergic reaction to CEFOTAN occurs, discontinue the drug. Serious acute hypersensitivity reactions may require epinephrine and other emergency measures.

Pseudomembranous colitis has been reported with the use of cephalosporins (and other broad-spectrum antibiotics); therefore, it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use.

Treatment with broad-spectrum antibiotics may alter normal flora of the colon and may permit overgrowth of clostridia. Studies indicate a toxin produced by *Clostridium difficile* is one primary cause of antibiotic-associated colitis. Cholestyramine and colestipol resins have been shown to bind the toxin in vitro.

Mild cases of colitis may respond to drug discontinuance alone. Moderate to severe cases should be managed with fluid, electrolyte, and protein supplementation as indicated. When the colitis is not relieved by drug discontinuance, or when it is severe, oral vancomycin is the treatment of choice for antibiotic-associated pseudomembranous colitis produced by *C difficile*. Other causes should also be considered.

PRECAUTIONS

GENERAL: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity. Those at risk include patients with renal or hepatic impairment, or poor nutritional state. Prothrombin times should be monitored in patients at risk and exogenous Vitamin K administered as indicated.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

INFORMATION FOR PATIENTS: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

DRUG INTERACTIONS: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycoside antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

DRUG/LABORATORY TEST INTERACTIONS: A false positive reaction for glucose in urine may occur with Benedict's or Fehling's solution.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels of Jaffe reaction and produce false increases in the levels of creatinine reported.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approx 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approx 2-4 times the usual human dose), only 1 of 10 treated animals was affected, and the degree of degeneration was mild. Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

USAGE IN PREGNANCY: Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

USAGE IN NURSING MOTHERS: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies the following adverse effects were considered related to CEFOTAN therapy.

Gastrointestinal symptoms occurred in 1.5 percent of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700).

Hematologic laboratory abnormalities occurred in 1.4 percent of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300).

Hepatic enzyme elevations occurred in 1.2 percent of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2 percent of patients and included rash (1 in 150) and itching (1 in 700).

Local effects were reported in less than one percent of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

DOSAGE AND ADMINISTRATION

TREATMENT: The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6* grams	3 g every 12 hours IV

*Maximum daily dosage should not exceed 6 grams.

PROPHYLAXIS: To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION: When renal function is impaired, a reduced dosage schedule must be employed. The following dosage guidelines may be used.

DOSAGE GUIDELINES FOR PATIENTS WITH IMPAIRED RENAL FUNCTION

Creatinine Clearance mL/min	Dose	Frequency
>30	Usual Recommended Dose*	Every 12 hours
10-30	Usual Recommended Dose*	Every 24 hours
<10	Usual Recommended Dose*	Every 48 hours

*Dose determined by the type and severity of infection, and susceptibility of the causative organism.

Cefotetan is dialyzable and it is recommended that for patients undergoing intermittent hemodialysis, one-quarter of the usual recommended dose be given every 24 hours on days between dialysis and one-half the usual recommended dose on the day of dialysis.

HOW SUPPLIED

CEFOTAN is a dry, white to pale yellow powder supplied in vials containing cefotetan disodium equivalent to 1 g and 2 g cefotetan activity for intravenous and intramuscular administration. The 1 g dose is available in 10 mL and 100 mL vials, and the 2 g dose is available in 20 mL and 100 mL vials. The vials should not be stored at temperatures above 22°C and should be protected from light.

1 g in 10 mL vial (NDC 0038-0376-10); 2 g in 20 mL vial (NDC 0038-0377-20); 1 g in 100 mL vial (NDC 0038-0376-11); 2 g in 100 mL vial (NDC 0038-0377-21)

Problems in General Surgery

Lloyd M. Nyhus, M.D., Editor.

This series of hardbound volumes features a symposium on a specific topic in general surgery in each issue. It serves as an outlet for the publication of original articles aimed at defining and suggesting solutions to difficult problems encountered in practice. Clinical problems are emphasized, with concentration on difficulties and complications. Leading authorities, chosen for their expert knowledge in their assigned topics, contribute articles on specific subjects, pooling the expertise of specialists for the benefit of generalists.

Published quarterly. Individual rate $59.00 per year (U.S.), $68.00 (elsewhere). Residents $39.00 (U.S. only).

Annals of Surgery

Official Publication of The American Surgical Association, The Southern Surgical Association, Philadelphia Academy of Surgery, and the New York Surgical Society

David C. Sabiston, Jr., M.D., Chairman of Editorial and Advisory Board.

Annals of Surgery—the world's oldest exclusively surgical journal—has provided the medical community with reports on significant contributions to the advancement of surgical science and practice for over 100 years. Its 20,000 subscribers find it a practical way to keep up to date with important developments in surgery.

Published monthly. Individual rate $53.00 per year (U.S.), $70.00 (elsewhere). Residents $35.00 (U.S.), $52.00 (Canada).

The American Surgeon

Official Publication of the Southeastern Surgical Congress, the Midwest Surgical Association, the Association of Clinical Anatomists, and the Society of American Gastrointestinal Endoscopic Surgeons (SAGES)

Arlie R. Mansberger, Jr., M.D., Editor-in-Chief.

An authoritative forum for the publication of original papers contributing to the advancement of surgery. Each issue contains information on the clinical application of new methods used in the management of patients; review articles with continuing education questions; condensed reviews of unusual case reports; "How I Do It" articles emphasizing the technical aspects of surgery.

Published monthly. Individual rate $49.00 per year (U.S.), $60.00 (elsewhere). Residents $32.00 (U.S. only).

Current Surgery

The Official Journal of the Association of Program Directors in Surgery

Lloyd M. Nyhus, M.D., Editor.

An internationally renowned editorial board prepares abstracts from every dependable source of surgical information throughout the world. Drawing on their own clinical experience and that of other recognized authorities, the members of the board provide commentary to further amplify and illuminate the material contained in each abstract. Also included are editorials, reports of new discoveries, residents' corner, and book reviews.

Published bimonthly. Individual rate $40.00 per year (U.S.), $46.00 (elsewhere). Residents $26.00 (U.S.), $32.00 (Canada).

Diseases of the Colon and Rectum

Official Journal of the American Society of Colon and Rectal Surgeons and the International Society of University Colon and Rectal Surgeons

Robert W. Beart, Jr., M.D., Editor-in-Chief.

This journal publishes reports on contemporary practice in the diagnosis and management of proctologic diseases and surgery. International in scope, it includes articles from physicians worldwide who share their important discoveries that offer new insights into basic research in metabolism, pathology, virology, radiology, and the clinical practice of medicine and surgery.

Published monthly. Individual rate $74.00 per year (U.S.), $89.00 (elsewhere). Residents $44.00 (U.S.), $59.00 (Canada).

Journal of Cardiovascular Surgery

Official Journal of the International Society for Cardiovascular Surgery

J. E. Connolly and S. S. Rose, Co-chief Editors.

The Journal is devoted to disease of the heart and the entire vascular system. It presents concise, informative coverage of the most significant work being done in diagnostic, experimental, and clinical surgery of the heart and blood vessels.

Published bimonthly. Individual rate $80.00 per year (North America only).

BECAUSE OF DORNIER, 500,000 PEOPLE HAVE HAD THEIR KIDNEY STONES REMOVED WITHOUT A SCRATCH.

Over the past three years, 500,000 people got some good news about kidney stone surgery — they didn't need it.

Instead, they underwent a revolutionary new technique — extracorporeal shock wave lithotripsy — a technique developed by a group of scientists at Dornier, the company that put 20 years of research into perfecting ESWL® technology.

Everything we've learned in those 20 years, and through our 500,000 successful treatments, has gone into today's Dornier lithotripters. And this experience makes us confident about comparing our proven clinical results with the claims of any newcomer to the field.

Our pioneer clinical success is unparalleled. Our goal is to constantly bring new advances to lithotripsy, the field we pioneered. This pursuit has led us from our original HM3 kidney lithotripter to the second generation non-water-bath HM4, dozens of which are treating patients right now.

And just on the horizon is the Dornier biliary lithotripter,* which has already been used clinically with hundreds of patients in Germany, and which is about to undergo clinical trials in the U.S.

Dornier is dedicated to lithotripsy alone. As lithotripsy evolves, it will be Dornier that will continue to bring you the state-of-the-art first. Because Dornier means lithotripsy.

For more information, contact Dornier Medical Systems, 824 Livingston Court, Marietta, GA 30067. Or 1-800-DORNIER.

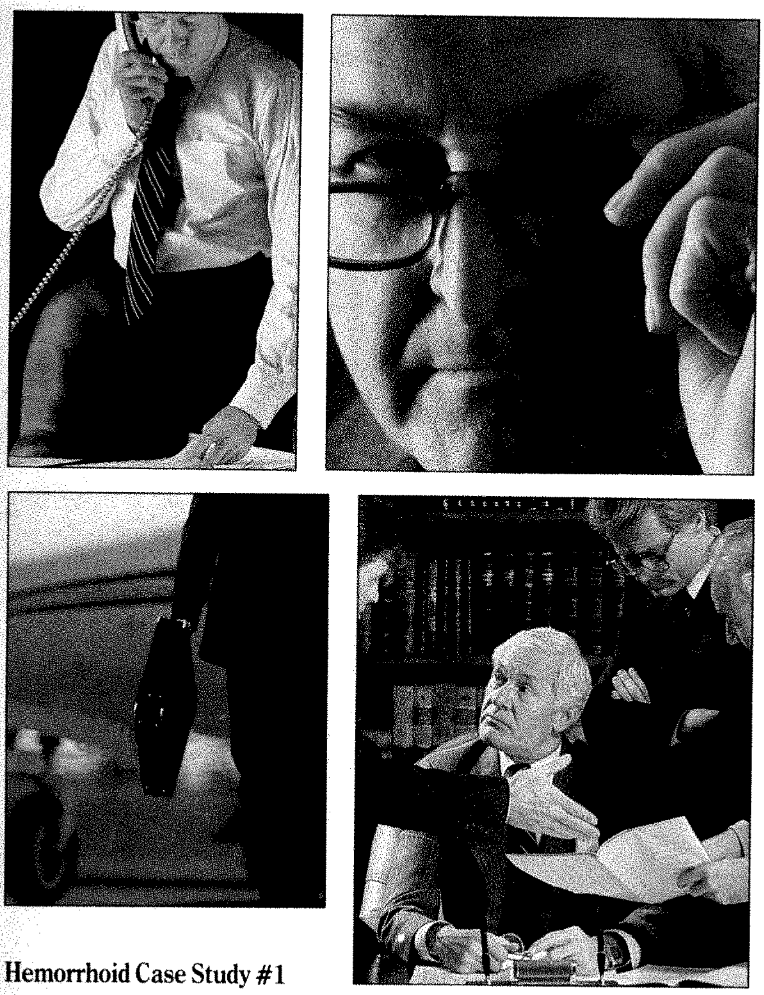
Striving for excellence . . .
Committed to a better future.

Do you really think he's going to sit still for a sitz bath?



Hemorrhoid Case Study #1

Patient: 56-year-old business executive.

Symptoms: Profuse rectal bleeding.

Diagnosis: Patient had undergone a hemorrhoidectomy ten years previously. Complete colonoscopy revealed normal findings except for the recurrence of several symptomatic Grade 2 internal hemorrhoids.

Treatment: Patient's travel and work schedule precluded compliance with prescribed treatment of sitz baths and suppositories three times a day. A decision was made to use ULTROID.™ Two 6-minute treatments at 16 milliamps were administered over a one-week period. Patient tolerated maximum milliamperage well and reported no pain during or after treatment.

Result: Patient reported no disruption to his work schedule or lifestyle. Subsequent postprocedure follow-up indicated no recurrence of symptomatic bleeding.

Hemorrhoids: A Problem Worth Solving.

The evidence is overwhelming. Every year 123,000 Americans undergo painful hemorrhoidectomies.[1] Millions more suffer from symptoms of itching, bleeding, and tissue prolapse through the rectum.

Patients with symptomatic hemorrhoids want immediate relief and a real solution.

ULTROID™: A Clinically Proven Solution.[2]

Now with ULTROID, Microvasive® introduces the future of nonsurgical hemorrhoid management. It is a monopolar, low-voltage treatment modality, clinically evaluated on hundreds of patients. ULTROID works biochemically at the feeding vasculature of the hemorrhoid's base. It leaves no visible ulceration or scarring.

ULTROID: Safe, Painless, and Effective.

ULTROID is the only modality that works on all four grades of symptomatic internal and mixed hemorrhoids. It works without cauterization, without burning. It can be used in your office, without special patient preparation or anesthesia. And, with ULTROID, patients experience no postprocedure pain or lifestyle disruption.

ULTROID: The New Treatment of Choice.

For more information on this new hemorrhoid treatment, our physician-moderated seminars, and product monograph, write or call our PHYSICIAN INFORMATION SERVICE, 800-225-3226.

Alcohol Protects Against Cholesterol Gallstone Formation

WAYNE H. SCHWESINGER, M.D.,* WILLIAM E. KURTIN, PH.D.,† and ROBBIE JOHNSON*

Epidemiologic studies have suggested that alcohol intake may protect against cholelithiasis. Gallstone formation was studied in 20 prairie dogs fed a 0.4% cholesterol-supplemented liquid diet. In ten animals, ethanol provided 35% of total calories. In ten pair-fed controls, ethanol was replaced with isocaloric maltose. After 3 months the gallbladders were inspected for gallstones, and gallbladder bile was analyzed. Cholesterol macroaggregates were present in all controls and pigment concretions were noted in five. No stones were observed in ethanol-fed animals. Bile in the ethanol group contained less cholesterol than the controls (5.60 ± 0.71 *vs.* 9.16 ± 0.61 mmol/L, $p < 0.05$) while phospholipids, total bile acids, and bilirubin were unchanged. The resulting cholesterol saturation index was reduced in the ethanol group (0.81 *vs.* 1.22, $p < 0.05$). The ratios of trihydroxy to dihydroxy bile acids were also different (2.07 ± 0.25 in ETOH *vs.* 3.29 in controls, $p < 0.05$). The bile calcium concentration was higher in control animals presumably secondary to the use of complex sugars (5.36 ± 0.37 *vs.* 3.77 ± 0.32 mmol/L, $p < 0.05$). These results confirm that ethanol inhibits cholesterol gallstone formation. They further suggest that this effect is dependent on reductions of biliary cholesterol and selective changes in bile acid concentrations.

From the Department of Surgery, University of Texas Health Science Center at San Antonio, and the Department of Chemistry,† Trinity University, San Antonio, Texas*

THE INFLUENCE of ethanol on cholelithiasis is still incompletely understood. In autopsy studies the prevalence of gallstones appears to be increased when alcoholic cirrhosis is present.[1,2] This finding is explained largely by an increment in pigment stone formation.[3,4] Cholesterol stones, in contrast, are reported only infrequently in cirrhotic patients who undergo cholecystectomy.[5,6] Moreover, epidemiologic surveys have suggested the intriguing possibility that biliary disease may actually be decreased by alcohol ingestion. In the Framingham study, the amount of alcohol consumed appeared to have an inverse relationship to the incidence of definite gallbladder disease, although this effect did not reach statistical significance.[7] Similarly, data from the Kaiser-Permanente cohort indicated that heavy drinkers had a risk of hospitalization for cholelithiasis, which was only one-third that for nondrinkers.[8] More recently, Scraggs et al. have reported a case control study of 267 patients with gallstones carefully matched to both community and hospital controls. They also noted that the consumption of alcohol was associated

with a substantial decrease in the prevalence of gallstones.[9]

Because the prairie dog has been shown to be a useful model for the study of various aspects of lithogenesis, the effects of oral ethanol in this animal were investigated. Ethanol administered as 35% of total calories prevented cholesterol stone formation. This protective effect was accompanied by changes in both bile acid distribution and biliary calcium concentration as well as by a relative cholesterol desaturation.

Materials and Methods

Animals and Diet

Twenty adult male prairie dogs (cynomys ludovicianus) weighing 0.6–1.4 kg were obtained from Otto M. Locke (New Braunfels, TX) and individually housed in a thermoregulated room (23–25 C). During a 2-week adaptation period the animals were fed a standard laboratory chow containing negligible cholesterol (Teklad, Madison, WI). They were then divided into pairs with the members matched in weight as closely as possible. Animals were pair-fed a commercially prepared, nutritionally complete semisynthetic liquid diet as the sole source of oral intake (Bioserv, Inc., Frenchtown, NJ). Experimental animals received a diet containing 0.4% cholesterol by weight to which ethanol was added to provide 35% of total calories. Previous experiments have demonstrated that this diet results in peak serum ethanol levels of 240–320 mg/dL. Control animals received an identical cholesterol-supplemented diet except that ethanol was replaced by equicaloric amounts of maltose–dextrin. Both diets were kept refrigerated in darkness in their dry form to minimize cholesterol oxidation and were reconstituted on alternate days.

At the end of 90 days, the prairie dogs were anesthetized and a celiotomy was performed. The common bile duct was cannulated with polyethylene tubing, the cystic duct ligated, and the gallbladder aspirated. One drop of gallbladder bile was examined under light and polarizing microscopy for biliary crystals.[10] The remaining gallbladder bile was frozen and stored for subsequent analysis. Measurements of hepatic bile flow were conducted for 1 hour. Blood was collected by cardiac puncture, allowed to clot and then centrifuged, after which serum was carefully aspirated and frozen. The gallbladders were removed, opened longitudinally, and inspected for stones. The animals were then killed with an intracardiac injection of T-61 Euthanasia Solution (Hoechst, Somerville, NJ).

Biochemical Analyses

Prior to analysis, frozen bile was rewarmed in a 37 C water bath and centrifuged for 5 minutes at 2000 rpm. Cholesterol content was determined using a commercial colorimetric assay kit based on the enzymatic oxidation of cholesterol (Sigma Diagnostics, St. Louis, MO). Total phospholipids were also measured enzymatically using the color reagent described by Qureshi et al.[11] and the method of Takayama et al.[12] Bile acids were determined by high performance liquid chromatography (HPLC) as described previously.[13] The column was a Microsorb C18 column (0.5 × 25 cm, Rainin Instrument Co., Inc., Woburn, MA), and the mobile phase was acetonitrile–methanol – 0.03 mol/L phosphate buffer, pH 3.4 (10:60:30). The flow rate was 1 mL/min and detection was at 204 nm using a LDC Spectromonitor D variable wavelength absorbance detector. Conjugated and unconjugated bilirubin were also determined by the method described previously.[13] HPLC was performed on a 25 cm Microsorb C18 column using 0.1 mol/L dioctylamine acetate in methanol as the eluting solvent. The flow rate was 0.75 mL/min and detection was by absorbance at 435 nm. All bilirubin analyses were conducted in dim red light. Total calcium concentrations were determined by atomic absorption spectrophotometry (Varian Instrument Co., Palo Alto, CA).

Quantitative Treatment of Data

All data are reported as mean ± SEM. Statistical comparisons of mean values among groups were assessed by the unpaired Student's t-test. Proportions were evaluated by the chi square test. Cholesterol saturation indices (CSI) were calculated from bile lipid data using the computer program of Kuroki et al.[14] as derived from the critical tables of Carey.[15]

Results

All animals appeared to tolerate the liquid diet without difficulty. Changes in total body weight recorded at the end of the experiment were small, and there was no significant difference in the weight changes (−0.10 ± 0.04 kg for control animals *vs.* −0.13 ± 0.06 kg for ethanol-fed animals).

Gallstone Formation

Upon gross inspection, the gallbladders of all control animals were found to be packed with aggregated cholesterol crystals or cholesterol stones. In addition, several small black concretions were visible in five of the ten control animals. Infrared spectroscopic analysis of one of these black deposits showed that it was composed of approximately 40% calcium bilirubinate by weight. By contrast, no cholesterol macroaggregates or pigment deposits or crystals were found in any of the ethanol animals by either gross or microscopic observation ($p < 0.001$).

TABLE 1. *Gallbladder Bile Composition*

	Control	Ethanol
Cholesterol (mmol/L)	9.2 ± 0.7	5.6 ± 0.7*
Bile salts (mmol/L)	146.9 ± 10.0	152.2 ± 11.1
Phospholipids (mmol/L)	20.0 ± 1.5	16.7 ± 1.3
Total lipids (mmol/L)	176.1 ± 11.7	174.4 ± 12.5
CSI	1.16 ± 0.02	0.80 ± 0.06*
Cholesterol:phospholipid ratio	0.46 ± 0.01	0.34 ± 0.03*
Total calcium (mmol/L)	5.49 ± 0.38	3.77 ± 0.35*
Unconjugated bilirubin (μmol/L)	10.8 ± 1.4	11.2 ± 2.6
Conjugated bilirubin (μmol/L)	183.5 ± 27.3	162.2 ± 29.0

* $p < 0.05$.

Hepatic Bile

Bile flow rate was measured at the time of hepatic bile collection. The difference found between the flow rates of the two groups approached but did not reach significance (0.7 ± 0.2 mL/h for control animals *vs.* 1.2 ± 0.2 mL/h for alcohol animals).

Gallbladder Bile

Analytic data for the major components of gallbladder bile in both control and ethanol groups are presented in Table 1. The mean cholesterol level was lower in the ethanol-fed animals by a factor of almost 2. Total bile salt concentrations were the same in the two groups, while phospholipid values were slightly, but not significantly, lower in the alcohol group. Total lipid concentrations were equal. The difference in cholesterol levels resulted in a significant difference in the CSI for the biles of ethanol and control animals. In the case of controls, the CSI of all biles was greater than 1, while in the ethanol group only one bile had a CSI greater than 1 (Fig. 1). In addition, the cholesterol:phospholipid ratio was significantly lower in the alcohol group. Although no difference was found in the concentration of total bile salts in the two experimental groups, marked changes did occur in the levels of specific bile salts. The changes in the major bile salts are summarized in Table 2. A significant increase in the total amount of dihydroxy bile salts was found in ethanol-fed animals. This increase was due in large part to a doubling in the mean concentration of taurochenodeoxycholic acid. At the same time a small decrease in the total amount of trihydroxy bile salts was found in the alcohol group compared to controls. These changes resulted in a decrease of the trihydroxy:dihydroxy bile salt ratio from a value of greater than 3:1 in controls to approximately 2:1 in the ethanol group ($p < 0.005$).

Total calcium concentrations in gallbladder bile were significantly lower in ethanol-fed animals when compared to controls. Unconjugated bilirubin values were the same in both groups. The biles of ethanol animals were found to have a small, but not significant, decrease in the concentration of conjugated bilirubin. The monoconjugated form of the pigment accounted for more than 95% of total bile pigments.

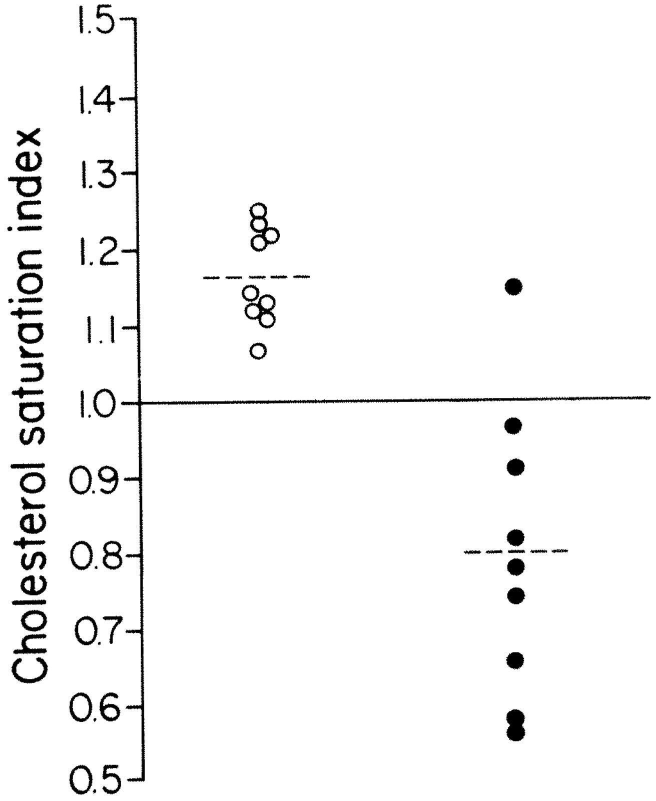

FIG. 1. CSIs are plotted for individual animals. Mean values (----) for control (○) and ethanol-fed (●) groups are significantly different ($p < 0.05$).

Discussion

Although epidemiologic studies have indicated that moderate alcohol intake reduces the risk of biliary disease, investigations of the mechanisms responsible for this effect have been hampered by serious methodologic problems. To overcome these difficulties, the prairie dog was chosen as the best model for study. In this animal the biliary lipid composition is similar to that of humans and becomes supersaturated with cholesterol when a lithogenic diet is provided.[16] As in humans, cholesterol

TABLE 2. *Bile Salts in Gallbladder Bile*

	Control	Ethanol
Taurocholic acid (mmol/L)	110.0 ± 7.5	97.5 ± 8.1
Taurochenodeoxycholic acid (mmol/L)	16.6 ± 1.4	35.6 ± 5.4*
Taurodeoxycholic acid (mmol/L)	18.8 ± 2.6	16.5 ± 3.3
Trihydroxy:dihydroxy ratio	3.19 ± 0.16	2.07 ± 0.3*

* $p < 0.005$.

lithogenesis then proceeds from the supersaturation phase through both crystal nucleation and stone growth phases. In these experiments, a liquid diet was used to overcome the natural aversion of prairie dogs to alcohol and to allow accurate pair feeding.[17] This approach ensured that each group received equal calories and nutrients; thus, the effect of nutritional intake alone should be minimized.

At the end of the 3-month study period, it was clear that ethanol administration had effectively prevented cholesterol precipitation and stone formation. In fact, bile samples from the gallbladders of ethanol-fed animals demonstrated no microscopic evidence of cholesterol crystals, indicating a high degree of solubilization. These results parallel those seen when other substances are used to arrest stone formation in the prairie dog such as hyodeoxycholic acid,[18] aspirin,[19] and the bile acid analog, ursodeoxyoxazaline.[20] The diversity of these litholytic substances and their putative mechanisms of action underscores the newly appreciated complexity of cholesterol gallstone formation.

In the current study, multiple factors appeared to be affected by alcohol administration. Notably, the CSI, a numerical approximation of the cholesterol-holding capacity of bile, was significantly lower in the ethanol group. All but one of the biles tested from this group were below unity, the defined point of cholesterol saturation. Conversely, all control biles were supersaturated with cholesterol. On this basis alone one would expect that no cholesterol monohydrate crystals would precipitate in ethanol-treated animals because cholesterol saturation is a necessary although not sufficient prerequisite for stone formation.[21] These results are similar to those of Thornton et al.[22] who found a decreased CSI in the bile of healthy human volunteers maintained for 6 weeks on moderate alcohol intake.

The reduction of the CSI in this model was largely accounted for by a significant decrease in the concentration of cholesterol in gallbladder bile. Decreases in biliary cholesterol output have previously been observed in association with ethanol administration in biliary fistula dogs[23] and in patients with cirrhosis.[24] Such a decrease in bile cholesterol promotes its complete solubilization by incorporation into either mixed micelles or phospholipid vesicles. This effect of long-term ethanol administration could be caused by a variety of mechanisms including a decrease in the intestinal uptake of cholesterol or modification of the hepatic regulatory pathways. Little information is available concerning cholesterol absorption during periods of alcohol ingestion. However, because it is predominantly a passive process, it is not likely to be greatly changed.[25] In one of the few reported studies, a slight enhancement of cholesterol uptake was noted to occur following the acute administration of ethanol to rabbits.[26]

Conflicting data have been published concerning the effect of ethanol on hepatic rate-limiting enzymes. The activity of HMG-CoA reductase, the enzyme responsible for hepatic cholesterogenesis, has been found to be both increased or decreased in rats fed ethanol for 3 weeks or more.[27,28] This study provides no specific information on this point. Interestingly, there is general agreement among these same authors that ethanol induces a reduction in the activity of the other major rate-limiting enzyme, cholesterol 7-alpha-hydroxylase, which is responsible for the degradation of cholesterol to bile acids. It is not known how this change affects the biliary dynamics of the prairie dog model, although it is cited as a contributory cause for cholesterol accumulation in the liver during ethanol feeding.[29]

Bile salts are essential to cholesterol solubilization because of their ability to form mixed micelles. In this study, the total bile salt concentrations in the gallbladder were not statistically different between groups. Other investigators have noted that chronic ethanol feeding results in increased bile acid output in animals.[30,31] However, Nestel et al.[32] found no change in normal humans who consumed ethanol as 37% of calories. Moreover, once cirrhosis develops, the size of the total bile acid pool is decreased mostly as a result of selective reductions in deoxycholic acid and cholic acid.[24]

Importantly, the size of the bile acid pool is also not the only critical factor in the solubilization of cholesterol, but the specific distribution of bile acids must also be considered. Thus, Carulli et al.[33] have observed that the hydrophilic–hydrophobic balance of bile salts helps to determine the capacity of bile to maintain cholesterol in solution. The trihydroxy bile acids, because they are more hydrophilic than the dihydroxy bile acids, are less effective solubilizers of cholesterol. In this regard, the ratio of trihydroxy to dihydroxy bile acids was significantly decreased by ethanol intake. The level of chenodeoxycholate, one of the major dihydroxy bile acids was significantly elevated in animals receiving ethanol. This selective increment is important because of the specific desaturating potential of this agent.[34] The reason for the enhancement of chenodeoxycholate in association with alcohol intake is not known. It is possible that either increased synthesis occurs through an alternate enzymatic pathway[35] or that bacterial dehydroxylation in the intestine is suppressed.[36] Thus, this accumulated data and the work of others suggest that qualitative changes in the bile acid composition of ethanol-treated animals may contribute substantially to the prevention of cholesterol gallstones.

Physicochemical factors other than supersaturation are also important in the modulation of cholesterol solubility, and these may be affected by ethanol. Recently, increasing attention has been focused on crystal nucleation and the role played by the bile salt-independent vesicular mode of cholesterol solubilization. In model systems of supersaturated bile the key determinants of the nucleation time have been found to include the total lipid concentration, the cholesterol:phospholipid ratio, and the Ca^{+2} concentration.[37] In this study, the concentration of total lipids was unchanged, but the cholesterol:phospholipid ratio was significantly lower in the ethanol group, a finding consistent with a prolonged nucleation time. This decrease indicates that fewer cholesterol molecules are incorporated into each phospholipid vesicle resulting in a more stable carrier state.[38]

The finding of an elevated biliary calcium in the control animals and pigment deposits in 50% of the same group was not unexpected; others have noted similar findings in cholesterol-fed prairie dogs and guinea pigs.[16,39] Based on a recent study by Conter et al.[40] it seems likely that the calcium bilirubinate concentrations in the control animals are related to the use of a complex sugar as the equicaloric substitute for ethanol. Conter et al.[40] noted increased concentrations of phospholipid, calcium, and bilirubin in the gallbladder bile of animals on a high carbohydrate diet. In this study, the concentration of calcium was elevated in the control animals when compared to ethanol-fed animals. In addition, values from previous experiments using prairie dogs maintained on nonmodified diets were the same as in the alcohol groups (unpublished observations). The calcium elevation seen in the controls may have been sufficient, however, to result in a calcium–bilirubin solubility product that exceeded the point of saturation. It is also possible that the elevated bile calcium in control animals actually promoted the more rapid nucleation of cholesterol crystals. Calcium is reported to significantly increase the metastability of unilamellar phospholipid–cholesterol vesicles[37] and acts as a pronucleating agent by accelerating cholesterol aggregation and precipitation in model bile solutions.[41]

Overall, these studies document that a major mechanism by which alcohol can protect against cholesterol gallstone formation is to induce changes in the concentration and solubilization of cholesterol itself. Still unresolved is the issue of whether alcohol administration causes significant additional perturbations of other important factors such as nucleation time, gallbladder motility, mucin production, or bile protein secretion.

DISCUSSION

DR. HENRY PITT (Baltimore, Maryland): First, let me state that I concur with the author's conclusions and believe that this paper is an important contribution that adds to other data which Dr. Schwesinger has reported on the influence of alcohol on bile composition. I have one concern, however, about the control group that was used in this experiment. You compared a high cholesterol/high alcohol diet to a high cholesterol/high carbohydrate diet. This control group may have been appropriate, but were the groups comparable in terms of the relative proportions of carbohydrates, fats, and proteins?

To fully interpret your data, I would have liked to have seen other control groups. For example, a low cholesterol group with and without alcohol, a high cholesterol group without alcohol, and a low cholesterol/high carbohydrate group would have added considerably to your study. If data from these additional groups support your observations, the conclusions you have drawn would be even more secure.

In reviewing the manuscript, I was also looking for other data. For example, do you have data from hepatic bile on biliary lipids, calcium, or bilirubin? With those data you could speculate as to whether the changes that you have observed are occurring in the gallbladder or in the liver. Also, do you have data on serum bilirubin and calcium? With this information, you might be able to state whether there were differences in intestinal absorption. You did provide data on serum cholesterol, which was lower in the animals receiving ethanol. In the discussion of your paper, however, you suggested that ethanol was not affecting cholesterol absorption. How, then, do you explain the lower serum cholesterols in the ethanol-fed animals?

I was also looking for the gallbladder volumes of the two study groups. You reported hepatic bile volumes and stated that their differences were not statistically different. Frequently, when the gallbladders of these animals become filled with stone and crystals, the gallbladder volume may change. Were the gallbladder volumes different in your two study groups? Finally, your own very elegant work has demonstrated that ethanol can cause hemolysis. With hemolysis, biliary levels of bilirubin should be increased. How, therefore, do you reconcile your previous observations with the present study in which biliary bilirubin levels were similar in the two study groups?

DR. FRANK G. MOODY (Houston, Texas): Dr. Schwesinger and his colleagues are to be commended for looking at a very important issue: the prevention of gallstones. Very soon we are going to have a large population of patients in which, for surgeons, this is going to be an important issue.

There are many alternatives to cholecystectomy currently being touted, and soon you will read about the German trial where over 160 patients were treated by extracorporeal shock wave lithotripsy with bile salt adjuvant therapy. You will be surprised to learn that 100% of those treated in this way during the course of a year were rendered free of their presumed cholesterol gallstones.

In addition, percutaneous techniques are being developed which employ mechanical lithotripsy or dissolution by methyl-tert-butyl-ether. Furthermore, stones can be fragmented within the common duct by extracorporeal shock wave or direct mechanical lithotripsy. And the newest technique, tunable dye laser lithotripsy, is proving to be effective and safe. These advances will no doubt rapidly transform our approach to the treatment of gallstones.

DR. JAMES PATRICK O'LEARY (Dallas, Texas): I would like to compliment Dr. Schwesinger on his paper and to thank him for allowing me to read it ahead of time. I commend it to your perusal when it is in its final published form.

I would like to ask several questions. The serum cholesterol levels were low. Lower in the ethanol group than in the control group. Bile cholesterol was also low.

That raises the question: Are we dealing with a problem of absorption? Where is the cholesterol going? This gets back to the way the diet was constructed. If you were putting the alcohol with the cholesterol in the diet, then perhaps we have some local effect in the gut lumen that might be impacting on cholesterol absorption. Therefore, the animals may not be challenged with quite the same amount of cholesterol.

Do these animals conjugate their bile salt with taurine. In humans, about 80% of bile salts are with conjugated glycine. If the percentage of conjugation is different, would this make a difference in the study?

My third question has to do with the histology of both the gallbladder wall and the liver. I suspect that you looked at both of these and I was wondering if cholecystitis or changes in hepatic architecture were present.

DR. WILLIAM CHEADLE (Louisville, Kentucky): I, too, would like to compliment the authors on a very elegant and clinically relevant study in an appropriate model with proper analytic methods. It is certainly interesting that pigment stones account primarily for the probable increased incidence of gallstones in cirrhotic patients; however, ingestion of moderate amounts of alcohol seem to be protective against cholesterol stone formation.

Dihydroxy bile acids such as taurochenodeoxycholic acid have been shown to have a detergent effect on hepatocytes which can cause feathery hepatocyte degeneration. The increase in the dihydroxy to trihydroxy bile acid ratio seen in these animals, therefore, might eventually cause low-grade chronic hepatotoxicity. Have you examined liver tissue histologically in this model or others, and have you analyzed common duct bile acid composition which might be different from gallbladder bile and more indicative of that which is in contact with the hepatocytes?

DR. GORDON L. HYDE (Lexington, Kentucky): I, too, would like to welcome the authors to the Southern Surgical Association and commend their work.

I do question how this applies to human physiology and have some concerns that this paper will be misinterpreted by many to mean that drinking alcohol is good for you and will prevent gallstones.

You touched on the fact that the study was performed in dogs; are we certain that species differences might not account for the findings?

Secondly, according to my calculations, ethanol provided 35% of the total caloric needs of these animals which would equate to six to eight drinks a day for a 3-month period, hardly a normal alcoholic intake. Is this a dose-related phenomenon?

Thirdly, the duration of the experiment was only for 3 months. We know that alcohol has a salutary effect on triglyceride metabolism in moderate doses, but has a serious adverse effect in long-term use. Might this possibly apply to cholesterol metabolism in the long-term model?

I can share with you that, as an alcoholic myself, I used the triglyceride information as a rationalization to drink, and thought that if a little bit was good for your blood vessels, then a lot should be even better! Being in recovery now for many years, I have had many friends relapse, misinterpreting data such as this and using it as an excuse to drink.

The drug alcohol has serious adverse effects in 10% of the population. In this group it can be fatal and certainly a far worse illness than cholelithiasis. Let us be aware of the effect of this drug on the whole patient. For most of you, this is no problem, but for some of us, it is serious.

Until the evidence if solid, please be aware that this kind of information can have an adverse effect on thousands of our alcoholic patients.

DR. LESTER WILLIAMS (Nashville, Tennessee): I had not planned to discuss this paper, but the authors' suggestion concerning mechanism leads me to ask two questions. Each has been suggested by others.

Was there anemia? As you know, in the prairie dog with the carbohydrate diet, when there is anemia, this changes the mechanism by which these animals get their stones, and changes the nature of the stones which they get.

The second one is based on an observation of a number of years ago. When we used alcohol as a vehicle for one of our medicines and did not pay attention to total alcohol dose, our animals didn't do well. In those animals, because the liver was histologically bad, it handled cholesterol differently. I wonder what evidence you have about the liver in these animals.

DR. WAYNE H. SCHWESINGER (Closing discussion): I would like to thank all the discussants for their insightful questions and their thoughtful comments.

Dr. Pitt, I would certainly agree that we need to be looking at the possibility of enrolling other control groups. It was not until the end of the experiment and on careful reflection on the calcium data that we recognized that we may have selected as a control, and I think a necessary control, one that induced its own abnormalities. It would be appropriate, of course, to do a four-way study. The limitations of space and money have prohibited that approach, and we have had to stagger some of these experiments. I think we will need in the future to do other types of controls to solve the questions about calcium changes.

We did make an effort to collect hepatic bile, but due to technical problems in several animals in both groups, the collections of hepatic bile were insufficient to allow us to do complete determinations. In fact, the small sample size explains why the standard error was so large that we could not show statistical significance in terms of volumes. What I *can* say is that based on limited evidence in that experiment there was no qualitative difference in the lipid composition of hepatic bile as compared to gallbladder bile. There were quantitative differences, of course, in terms of concentrations, a reflection of the ability of the gallbladder to concentrate the lipids many times. So far as we could tell on this limited data, there were no major differences in the distribution of the cholesterol bile acids or phospholipids.

We have, in the past, demonstrated that ethanol administration is, in a variety of animal models, associated with intravascular hemolysis and increases in bilirubin in the hepatic and gallbladder bile. In our hands, however, those experiments require the intravenous administration of ethanol. When we administered ethanol orally, the hemolysis disappeared, so that the data we have in the current study does not contrast with the data that we have presented before related to hemolysis.

I am aware that in other animal models, hemolysis is thought to occur secondary even to oral ingestion. In particular, in the rat experiments done by Lieber there has been some evidence of increased unconjugated bilirubin in bile following ingestion of alcohol. That did not appear to be the case here, and these animals (to answer another question) were not anemic as compared with the control animals.

I appreciate Dr. Moody's underscoring of the importance of developments in the field of fragmentation of cholesterol stones by lithotripsy. I think that one of the things on the horizon facing general surgeons is the fact that many patients with asymptomatic gallbladder disease will be treated with the lithotriptor and then maintained on some type of chenolytic agent. I am not suggesting that alcohol be that agent, but it does give us some physiologic information about the kinds of substances that can cause a reduction in the cholesterol saturation index.

I am interested to hear that ethanol improves evacuation of the gallbladder in animals. Whether ethanol influenced gallbladder motility has been studied in humans before, and to my knowledge, was not the case. In experimental animals with better control, one might be demonstrating an important factor in the management of cholesterol gallstones. Nonetheless, one cannot overlook the fact that in the ethanol-treated animals, the predominant biologic change was the reduction of the cholesterol saturation index. It may be that a number of factors are responsible for this reduction in the incidence of stones.

Dr. Moody asked what would be an equivalent amount of Scotch? We plotted it out on the basis of the animals that we were dealing with and found that one would really have to drink probably half a bottle of Scotch or more to keep up with most of the animals. It is not the usual social dose of alcohol! We selected this dose because it is a dose that is typically used in research with rodents with alcohol and liquid diets. 35 to 37% is the level that is recommended for studies of the induction of enzyme systems and minimal changes in liver histology.

If I may have Slide No.30, I will demonstrate some of the changes that we see in liver histology. (Slide) We did obtain, of course, liver and gallbladder specimens, and what we saw was a range of changes. In this animal in the alcohol group, the liver histology was preserved normally. In contrast, in one of the other ethanol-fed animals, a moderate degree of lipid within the hepatocytes was documented. In a single animal, in the ethanol group, we actually see some periportal inflammation. No scar formation, however, and no necrosis was noted in any of the histologic specimens. Of interest, while we tried to rank the various changes in control and alcohol animals, the control animals had mild degree of fat in their liver as well, so it was impossible for us to demonstrate a statistically significant difference in histology.

Concerning the toxicity of dihydroxy bile acids as detergents that can affect hepatocytes: I would agree that is a possibility and has been documented even in patients receiving chenodeoxycholic acid for dissolution. However, again as was demonstrated in the liver slides that we reviewed, we found no necrosis or any severe evidence of damage.

Dr. Hyde, I certainly would accept the caveats which you raised about this topic, and I would be irresponsible if I should allow myself to be misinterpreted as suggesting that alcohol deserves to be used to prevent gallstones. I hope that the manuscript is clear in avoiding that conclusion. Certainly the doses we are talking about, as I have explained, were selected because they have been used by other investigators. Other lower doses will be used. I am, of course, not an advocate of irresponsible behavior for myself or others, and I think one does need to use caution when submitting this type of work. Thank you for bringing our attention to that concern.

There are, I am sure, many other questions. I think I have answered most. I greatly appreciated the opportunity to present this material.

Intraoperative Radiotherapy for Patients with Carcinoma of the Pancreas

The Howard University Hospital Experience, 1978–1986

WAYNE B. TUCKSON, M.D., ALFRED L. GOLDSON, M.D., EBRAHIM ASHAYERI, M.D.,
MICHELLE HALYARD-RICHARDSON, M.D., ROBERT L. DEWITTY, M.D., and LASALLE D. LEFFALL, JR., M.D.

During the period from 1978 to 1986, 106 patients were diagnosed with carcinoma of the pancreas; 30 of these patients were excluded from this study. Of the remaining 76 patients, 40 did not receive intraoperative radiotherapy (IORT) and were used as the nonrandomized control group for the 36 patients who did receive IORT after histologic confirmation of carcinoma of the pancreas. The records of 35 patients were available for review. The group receiving IORT ranged in ages from 43 to 89 years (20 males and 15 females). Seventeen patients had distant metastatic disease. The primary was located in the head of the pancreas in 32 and the body in three. No patient in this group had a curative resection. All patients were treated by a combination of biliary and gastric bypass prior to or concurrent with IORT. IORT was begun only after obtaining a histologic diagnosis and prior to the completion of any anastomosis. Necrotizing pancreatitis occurred in the treated group. There was no statistically significant difference in the survival of the nonrandomized control and treated groups.

From the Departments of Radiotherapy and Surgery, Howard University Hospital, Washington, DC

CARCINOMA of the pancreas is the fifth leading cause of death from cancer in the United States. Several centers are now using intraoperative radiotherapy (IORT) in patients with localized, nonresectable carcinoma of the pancreas to provide a boost dose directly to the tumor in an attempt to increase survival. IORT has been incorporated with several other treatment modalities including chemotherapy, surgical procedures (resection or bypass), external beam radiation therapy, and sensitizers. The safety of such treatment has been demonstrated. Except for the results reported from the Massachusetts General Hospital adding misonidazole to IORT and external beam therapy,[1,2] the median survival of those having received IORT has been 8.8–12 months. The paucity of major complications in recently treated patients coupled with apparent retardation of local disease and demonstrable necrosis of the tumor in the pancreas suggests that this treatment modality has value in some patients. The records of all patients at the authors' institution diagnosed as having carcinoma of the pancreas from 1978 to 1986 were reviewed. The treatment results are reported for those patients who received IORT with bypass procedures alone or in combination with iodine 125 implantation, external beam radiotherapy, chemotherapy, and/or intraoperative hyperthermia.

Materials and Methods

From 1978 to 1986, 106 patients were diagnosed as having carcinoma of the pancreas. In 19 patients the diagnosis was made on clinical grounds without histologic confirmation. Eleven had been diagnosed and treated at other medical centers and were admitted to the authors' institution in a moribund condition. These 30 patients were excluded from this study. Of the remaining 76 evaluable patients, 40 did not receive IORT and were used as a nonrandomized control group for the 36 patients who did receive IORT with 35 of the latter records available for review.

The control group included 15 patients who were diagnosed but not treated, one patient who had a curative pancreaticoduodenal resection, 20 patients who had gastric and biliary bypass only, three patients who received bypass and external beam therapy, and one patient who received bypass and iodine 125 implantation. Patients in this group did not receive IORT because of the following: (1) inability to confirm the diagnosis on frozen section; (2) inability to isolate the tumor from surrounding structures; (3) bulky distant metastatic disease; (4) death occurring prior to the treatment date; and

---

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

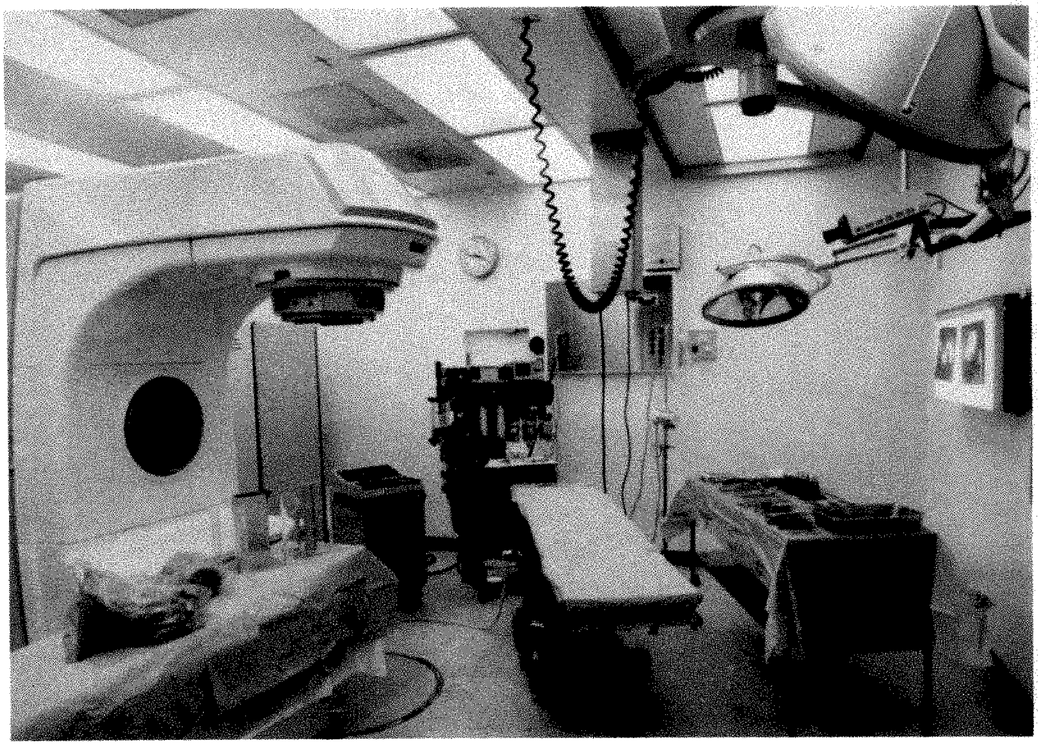

FIG. 1. The Howard University Hospital Intraoperative Radiotherapy suite consists of a standard operating room combined with a Clinac 18 Linear Accelerator, which can deliver electron beams of 6, 9, 12, 15, or 18 meV.

(5) patient refusal. Patients ranged in age from 36 to 92 years (average: 66.9 years) and included 16 males and 24 females. Twenty-six patients reported weight loss ranging from 8 to 65 lb (average: 24 lb). Twenty-one patients had distant metastatic disease on presentation and the primary was in the head in 38 and body and tail in two.

The 35 patients receiving IORT ranged in age from 43 to 89 years and included 20 males and 15 females. The duration of symptoms prior to the institution of therapy ranged from 2 weeks to 13 months. Twenty-one patients on presentation reported weight loss that ranged from 15 to 70 lb (average: 31.6 lb). Symptoms and physical findings were similar to those reported in other series. Seventeen patients had distant metastatic disease found at operation with the primary located in the head of the pancreas in 32 and the body in three. Twelve patients with distant metastases were treated during the Phase I toxicity study to determine side effects and complications of IORT.[3] No patients treated with IORT had bulky distant metastases. All patients had nonresectable lesions. Preoperative and postoperative enteral and parenteral hyperalimentation was liberally utilized.

Patients were administered general anesthesia in a special IORT suite and prepped and draped in the usual manner (Fig. 1).[4] Surgery and radiotherapy were initiated and terminated in the suite; patient transportation was not required. To achieve maximal visualization for both exploration and IORT, a bilateral subcostal surgical incision was usually employed. Once the tumor was exposed and staged, a wedge biopsy or preferably a transduodenal needle biopsy was performed to obtain frozen section confirmation of the diagnosis. No attempts were made for partial or total resection of the primary. The appropriate electron beam energy and specific applicator (collimator) size, which allowed for at least a 1–2 cm margin of normal tissue, were assessed by palpation and direct measurement of the visualized tumor.

The normal uninvolved intra-abdominal structures were then retracted from the treatment field while the applicator was placed down over the tumor. The transparent acrylic (Lucite) portion of the applicator, which is in contact with the tumor surface, permits direct viewing of the radiation field through its sides, and at the same time restrains the uninvolved bowel outside of the direct radiation port (Fig. 2).

All treatments were given with electron beams with energies of 9, 12, 15, or 18 meV, with 80–90% depth dose distributions of 3, 4, and 5 cm. The rapid and sharp fall-off in depth dose of electrons is attractive for the intraoperative technique because it limits the exit dose to normal structures, such as the spinal cord, which lies posterior to the tumor. Circular treatment cones of 6.0, 7.5, 8.5, and 9.6 cm in diameter were used to treat the pancreatic lesions. These cones were adequate in treating the well-circumscribed lesions of the pancreas; however, given the multicentricity of many pancreatic malignancies, larger cones of probable rectangular shape may be more efficacious when one considers treating the whole pancreas by the intraoperative technique. Step-

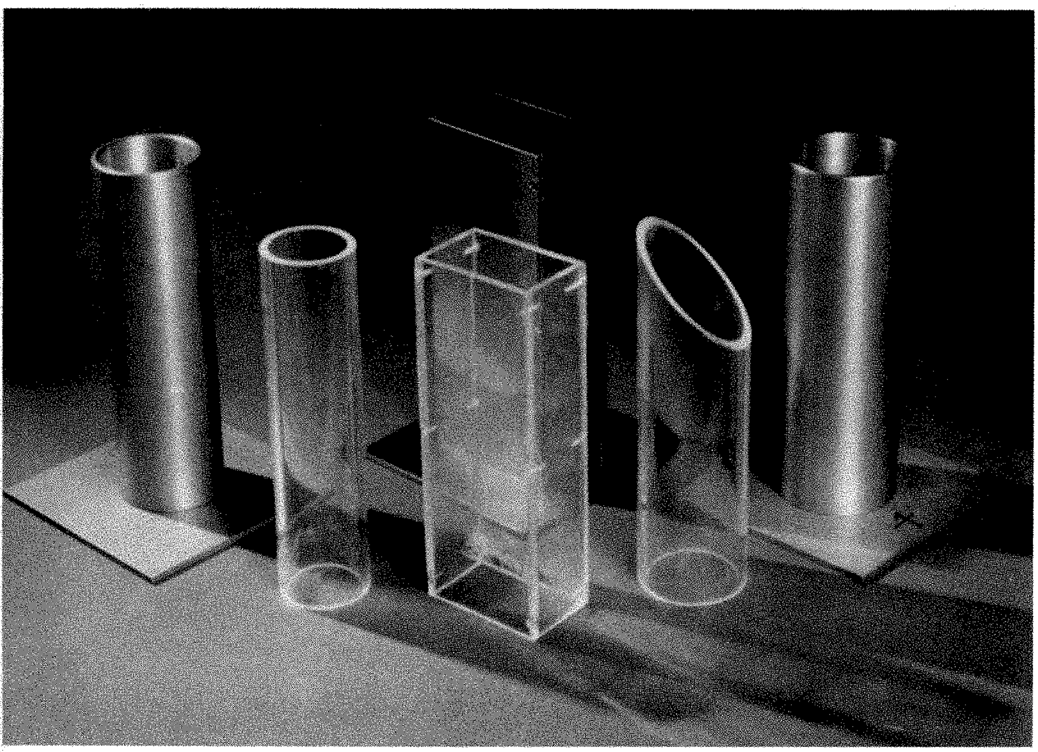

FIG. 2. These represent special electron beam collimators for IORT. The outer part is made of aluminum and is attached to the head of the accelerator; the inner part is made of acrylic and can telescope into the outer aluminum part.

wise decremental doses from 3000, 2500, 2000, and 1500 cGy were given in single doses in the Phase I study. The remaining patients received 2500 cGy as a boost dose plus fractionated external beam photons (usually 4000–4500 cGy). The irradiated volumes, which included the pancreas, its regional lymph nodes, and portions of the duodenum, varied from 30 to 180 cm^3.

During the interval of irradiation all members of the surgical team left the surgical radiotherapeutic suite. The patients' vital signs were monitored remotely via an oscilloscope mounted just above the treatment console control panel. Additional monitoring was achieved indirectly through a mirror system and the television camera mounted on the wall inside the treatment room.

Biliary and gastric diverting procedures were performed after completion of the IORT to avoid further operative trauma and irradiation to new anastomoses. After closure of the surgical wound, patients were transported to the surgical intensive care unit for observation. No special radiotherapy precautions were indicated.

TABLE 1. *Number of Patients Treated, Presence or Absence of Distant Metastases, and Survival Rates*

No. of Patients	Metastases*	Treatment IORT +	Survival (mo)
21	13	Bypass only	6.2
6	3	External beam	8.8
5	0	External beam and iodine 125	8.2
2	1	External beam and chemotherapy	6.7
1	0	External beam and IOHT	22

* Distant metastases did not alter survival.

Therapy and Results

IORT was given in various combinations including (1) bypass only; (2) bypass and external beam therapy; (3) bypass, external beam, and iodine 125 implantation; (4) bypass, chemotherapy, and external beam therapy; and (5) bypass, external beam, and intraoperative hyperthermia (IOHT). These data including survival rates are outlined in Table 1.

One patient was a 56-year-old man who received simultaneous IORT (2500 cGy) and IOHT (43–44 C for 40 minutes) with additional postoperative fractionated external beam irradiation (2000 cGy). Postoperatively, the patient complained of persistent midepigastric pain ultimately requiring implantation of a morphine pump. He survived for 22 months with good quality of life until his last 2 weeks. He died of massive upper gastrointestinal hemorrhage. Results of an autopsy are pending.

Only one patient in the series was still alive functioning fairly well but with progressive disease 11 months after treatment with IORT, chemotherapy, and external beam. Fifty seven per cent of patients receiving IORT had significant relief of abdominal pain within 1–2 weeks after treatment. In a nonrandomized control group of 40 patients treated with varying modalities, the survival rate was 5.4 months.

Metastases

Of the five aforementioned treatment groups, no liver or other distant metastases were present in the five patients treated with iodine implantation or in the one patient treated with hyperthermia. One of two patients treated with chemotherapy had liver metastases as did three of six treated with external beam and 13 of 21 treated with IORT alone (Table 1). There was no statistically significant difference in survival in patients with or without distant metastases.

Complications

During the Phase I study involving 19 patients, there were three perioperative deaths and three late complications. The complications were: (1) massive upper gastrointestinal hemorrhage from erosion into the superior mesenteric artery resulting in the death of a 65-year-old male 6.5 months after IORT; (2) posterior gastric wall ulcer in a 73-year-old patient who expired 3 months after treatment with massive tumor necrosis; and (3) ascending cholangitis and common bile duct stricture in a 52-year-old patient who died 3 months after treatment. All three patients had treatment volumes greater than 100 cm.^{3} Two patients received 3000 cGy and one received 2000 cGy. The three perioperative deaths in this group were intraoperative cerebrovascular accident, postoperative hemorrhage secondary to needle biopsy injury to vascular structures, and hepatorenal syndrome and aspiration in a patient with poor liver function. Of the remaining 16 patients, two developed necrotizing pancreatitis and pancreatic abscess: a 72-year-old man treated with IORT and external beam therapy who expired 2 months after treatment and a 56-year-old woman treated with IORT and iodine 125 implantation who died 5 months after treatment. Both had open wedge biopsy because transduodenal biopsy was inconclusive.

There was no delayed wound healing. Relatively minor complications included two patients with gastritis and seven patients with prolonged gastric atony in whom portions of the stomach and duodenum were included in the radiation field. Autopsies obtained on eight patients revealed massive tumor necrosis, mild fibrosis, and islands of viable cancer.

Discussion

There has been continuing interest in the role of IORT for pancreatic cancer since Abe and Takahasi introduced this modality in 1964.[5] Howard University Hospital in 1976 was the first institution in the United States to use IORT and began its Phase I study for carcinoma of the pancreas in 1978. The most recent report from Abe et al. suggested that IORT in combination with external beam radiotherapy may improve survival in pancreatic cancer.[6] They reported the results of 110 patients with locally advanced disease who were entered into the pilot study.[6] Forty-nine patients were treated by IORT alone (Group 1), 20 patients were treated by IORT followed by external beam radiotherapy (Group 2), and 41 patients were treated by operation alone (Group 3). The IORT dose for patients treated by IORT without external beam irradiation ranged from 3500 to 5500 rads depending on the residual tumor volume and tumor site. For those who were treated by IORT plus external beam irradiation, the IORT dose was 1000–2500 cGy, whereas external beam radiation started 3–4 weeks after IORT had a dosage ranging from 3500 to 5500 cGy with an average of 4000 cGy. The median survivals were 5.5 months for Group 1, 12.0 months for Group 2, and 5.5 months for Group 3. About 70% of their patients who complained of severe abdominal or back pain experienced relief within a week after IORT while 57% of these patients had relief within 1–2 weeks. Approximately 30% of their patients with pancreatic head cancer who received an IORT dose of more than 2500 cGy experienced diarrhea and/or bloody stool and about 10% developed duodenal ulcers. Other complications included prepyloric obstruction in one patient, death probably secondary to acute pancreatic necrosis in another patient, and two patients with delayed gastrointestinal tract bleeding. The most encouraging results for this difficult clinical problem have been reported by groups using intraoperative radiotherapy as a boost in external beam radiotherapy. The advantages of a combined IORT and external beam treatment are as follows: (1) it is difficult to eliminate a bulky tumor by a single IORT dose; (2) a higher dose can be delivered to tumors by external beam plus IORT boost with less risk of adjacent normal tissue necrosis; and (3) the risk of marginal recurrence may be decreased by external beam irradiation.[6,7]

The results of early clinical work from Japan, which were partly supported by experimental animal studies suggested there were few long-term complications to retroperitoneal structures from IORT.[5] The acute and late responses of normal canine tissues to large single doses of electron radiation indicated that the major retroperitoneal blood vessels, which were most frequently and unavoidably irradiated, had a high tolerance, while the hollow viscera and solid organs were more sensitive than retroperitoneal structures. In the abdominal solid organs, doses between 2000 and 3000 cGy, in general, led to moderate inflammation, cellular atrophy, and fibrosis. Partial irradiation of the duodenum with doses of 2000–4500 cGy resulted in duodenal narrowing, but as long as the total circumference was not irradiated or the loop of intestine was nonfunctional, stenosis was minimized. Safe clinical practice based on these studies, however, nearly always requires surgical bypass of the biliary or gastrointestinal tract if any portion of these organs receive any IORT dose.[8,9]

Dobelbower et al.,[10] Shipley et al.,[11] and Syed et al.[12] reported median survival times of 11–15 months in patients treated with combination interstitial iodine 125 implant and external irradiation. Rich[13] reported that radiation therapy for 41 patients with unresectable pancreatic cancer resulted in a median survival of 7 months. There was no difference in median survival for patients receiving external beam alone, IORT plus external beam, or gold 198 implant with or without external beam irradiation.[13]

Wood et al. reported 12 patients treated with external photon beam and intraoperative electron beam irradiation who had a median survival of 15 months or more.[14] This survival rate is contrasted with 12 months for patients treated with iodine 125 seeds as boost irradiation and less than 10 months for patients with unresectable disease treated by external beam irradiation and chemotherapy by the Gastrointestinal Tumor Study Group. Six of the 12 patients received chemotherapy. The combination of tailored external beam irradiation and intraoperative boost provided an average tumor dose of 6225 cGy, which is the biologic equivalent of 8700 cGy of conventionally fractionated radiation therapy. Complications occurred in all three patients who had the distal stomach and pylorus included in the intraoperative irradiation field—gastric outlet obstruction, pancreatic abscess, and suture line leak.

Shipley et al.[2] reported the results of 29 patients treated by electron beam IORT plus conventional external beam radiation therapy. Adjuvant chemotherapy (FAM—5 fluorouracil, adriamycin, and mitomycin-C) was given to 23 of the 29 patients while the last 13 patients in the series also received intravenous (I.V.) misonidazole, a drug that sensitizes hypoxic cells to radiation. Their median survival was 16.5 months. Studies with misonidazole are continuing, but these investigators believe that the continued use of misonidazole in this setting is not warranted.[1]

Gunderson et al.[15] reported a similar median survival time of 11–12 months for patients treated with IORT plus external beam irradiation or external beam therapy alone. Fifty-two patients were treated with an IORT dose of 1750 cGy (two patients) or 2000 cGy (50 patients) plus 4500–5000 cGy of fractionated external beam irradiation. They have begun a Phase II pilot trial, which combines upper or total abdominal irradiation and infusion of 5-fluorouracil with tumor nodal irradiation plus IORT to evaluate tolerance and the relative incidence of abdominal failures.[16]

Because of these laboratory studies and the results with the one patient treated with simultaneous IORT and intraoperative hyperthermia followed by external beam therapy, the authors have begun a study using a combination of these modalities.[17] This therapeutic approach has not been used previously for nonresectable pancreatic cancer. The rationale for hyperthermia in cancer therapy is based on various biologic effects that have been confirmed in many *in vitro* and *in vivo* studies: (1) hyperthermia kills cells exponentially as a function of time and temperature at or above 43 C; (2) hyperthermia selectively kills S-phase and other radioresistant cells, such as hypoxic tumor cells, acidic cells, and nutritionally deprived cells; (3) hyperthermia not only complements but also acts synergistically with ionizing radiation by inhibiting DNA repair by heat shock proteins or by interacting with cellular membrane structures; and (4) hyperthermia interacts synergistically with cytotoxic agents and can overcome some kinds of drug resistance by various mechanisms, *e.g.*, increasing intracellular drug uptake, inhibiting repair mechanisms, and increasing drug activity. Clinical trials using radiation therapy and adjuvant hyperthermia compared with radiation therapy alone have demonstrated an improvement in partial and complete response rates with the addition of hyperthermia. Overall complete response rates for radiation alone are 30–40% compared with 70–80% for the combined modality approach.[18-21]

Conclusion

Although IORT has been used for over 50 years, there is now renewed enthusiasm especially with the use of electron beam techniques, which have improved the ability to deliver high intraoperative radiation doses safely. The number of patients in this series is too small to render any definite conclusions. Fifty-seven per cent of these patients had significant relief of severe abdominal and back pain. There was no statistically significant difference in survival whether or not patients were treated with IORT. Nevertheless, with the dismal outlook for patients with cancer of the pancreas, further studies with IORT appear warranted.

DISCUSSION

DR. J. SHELTON HORSLEY III (Richmond, Virginia): It is a pleasure to welcome LaSalle Leffall to membership in the Southern Surgical Association and congratulate him on this excellent presentation.

We have followed the work that Howard University has done in intraoperative radiation therapy. They have been at the forefront of this very interesting field. We do not have this capacity at the Medical College of Virginia, so we have no personal experience.

Dr. Leffall has outlined the pitfalls and very objectively analyzed his results. I am glad he is moving forward in this field, because I think it does have something to offer in selected areas. People with the expertise and facilities to do this should continue with this investigational type of therapeutic approach.

I think one of the exciting things about this work is the pain control. As he pointed out, 57% of his patients got pain control within 1 to 2 weeks. The Japanese experience is some 70%. Pain control is a truly positive result in patients with carcinoma of the pancreas.

I also call to your attention that this has been utilized in other areas of the gastrointestinal tract. The Massachusetts General Hospital and the Mayo Clinic have utilized pain control with rectal carcinoma, and their results, utilizing preoperative radiation therapy followed by resection and intraoperative radiation therapy, have actually shown a significant improvement in survival and decrease in local recurrence, as compared to preoperative radiation and surgical resection.

I would like to ask Dr. Leffall: Does he think there is a place for intraoperative radiation therapy following pancreatic resection, such as a Whipple operation, for carcinoma of the head of the pancreas?

We will follow this work with great interest, and we wish him well.

DR. HARRIS B. SHUMACKER (Bethesda, Maryland): It is a great pleasure for me to listen to LaSalle Leffall present this new work. He knows in what high regard I hold him and how much my colleagues and I in Bethesda enjoy his frequent visits to Walter Reed Army Medical Center as the person in charge of grand rounds.

The other day when I was trying to straighten out my continually disordered office, I ran across a four-line letter from Ronald Malt of the Massachusetts General addressed to Ian Munro, Editor of the Lancet. It says:

"Perhaps the author of your 'Intraoperative Radiotherapy' (10 December 1983) might want to know that between 1937 and 1942, Leo Eloesser of San Francisco . . . started a series of radiation of 300–400 Roentgens through the open mastectomy wound for breast cancer."

His reference is to the biography of Leo Eloesser, subtitled "Eulogy for a Free Spirit," which I wrote some years ago now. (I am not trying to sell my biography, but I do recommend it.)

While I do not think that in preparing a paper it is necessary to go beyond the medical literature and read every biography written for information of the past, I knew that LaSalle, being the scholar that he is, would have covered the past contributions in this particular area. Dr. Eloesser's work at the San Francisco County Hospital was not published because the results were not very conclusive and because prior publications were known to him.

I mention his work to point out the splendid opportunity we have had in 1987 and the preceding years to do with ease things that were so cumbersome a few years ago.

Leo Eloesser, his associates, and his residents have told me how laborious it was to try to pick a patient up from the operating table of the old County Hospital and maintain some semblance of sterility, then place the patient on a stretcher, carry the patient out of the operating room and down the hallway to a rickety old elevator in the *next* hallway, down the elevator to the therapy department, and then reverse the entire procedure. With what ease LaSalle can accomplish all of this in the operating rooms at Howard University!

Mr. President, may I make an entirely irrelevant comment? (Actually, it is not entirely irrelevant, since this meeting began with those beautiful audiovisually recorded words of welcome and congratulations from our President and Mrs. Reagan.)

A few years ago, when it was necessary for President Reagan to have a colectomy for what appeared to be, from all preoperative studies, a favorable lesion of the cecum it was felt necessary at that time to have a surgical oncological observer on hand. Had I had the right to decide whether this was necessary or not, I would have made the decision that it was not. I knew that the President's operation was in good hands, that it would go as uneventfully as it did; but had I decided that it was necessary to have an oncological specialist standing by, I would have selected from the neighborhood Dr. LaSalle Leffall, and that would have had one very beneficial effect. We wouldn't have seen the same face on television so often. In fact, I am sure we wouldn't have seen a face at all on television, nor would we have heard so many comments, both relevant and irrelevant, about what took place on that historic date, for Dr. Leffall would surely have remained as quietly in the background as did the Chief of Surgery at the Navy Hospital, Dale Oller, who operated on our president so skillfully. It would have perhaps had an *adverse* effect in that it would have made those who are so antagonistic to everything that happens in the White House even more antagonistic than they were and are, but it might have also had one other bad effect. It might have delayed the current managment of dissemination of medical news about those in our First Family, which is now handled so beautifully by Colonel John Hutton.

At the present time, the correspondents are informed nicely but emphatically that they are not welcome at Navy Bethesda Hospital or any other place where the First Family might be treated. Still, they are welcome around the White House, where concise and well prepared handouts will frequently be available to them, describing not only what treatment has been given, but what is on-going. This has worked out very well and has saved our President, and especially his First Lady, a great deal of agonizing discomfort.

LaSalle, we congratulate you on a very interesting study. There is only one thing that I would like to ask. I have the impression that, 8 or 10 years ago, the combination of external radiation with general body hyperthermia did not work out to be any panacea for the treatment of adenocarcinoma, and I wonder whether localized hyperpyrexia and intensive local radiation would have a different effect.

DR. KIRK MARTIN (Jacksonville, Florida): I would like to congratulate Dr. Leffall and to express my appreciation for his allowing me to review his excellent, detailed manuscript.

We are indebted to him for his early pioneering work on intraoperative radiotherapy in the United States.

We became involved with intraoperative radiotherapy through an NCI contract in late 1980, and to date, we have used intraoperative radiation to treat 64 patients with locally unresectable pancreatic cancer, and an additional four with residual disease following pancreatectomy.

Last year, we compared our treatment of locally unresectable—that is, no distant metastases— ductal pancreatic carcinoma, and the results are very similar to the Howard experience that was so superbly presented.

Allow me to briefly summarize our findings and then ask Dr. Leffall a question.

Between 1981 and 1985 we treated 37 patients with an intraoperative radiation boost, generally 20 Gray using 18 Mev electrons, followed by 45 to 50 Gray external photon beam. We compared this to 122 patients treated by external beam radiation alone in doses ranging from 40 to 60 Gray. The patients were matched according to tumor characteristics and performance status.

There was no difference in survival between external beam alone and external beam plus intraoperative radiotherapy: 12.6 months and 13 months, respectively.

One-year and two-year survival was also similar, 55 *versus* 58% and 16.5 *versus* 12%.

Distant metastases occurred in equal numbers in both groups. Liver 40%; peritoneal seeding, 30%; lung, 20%. Multivariate analysis showed a significant difference only for local recurrence rates: 16% failure in the intraoperative *versus* 72% failure rate in the external beam alone group.

These data plus those of others led us largely to abandon intraoperative radiation therapy for unresectable pancreatic carcinoma. We have utilized celiac block for pain control.

While intraoperative electrons may be of significant value in other sites, such as residual colorectal cancers, I would like to ask Dr. Leffall if, until more effective systemic treatment is available, they still feel intraoperative radiation is justifiable in patients with unresectable pancreatic carcinoma.

DR. LLOYD M. NYHUS (Chicago, Illinois): I suppose you are all wondering why I rise to discuss this paper. The experience that we have had with intraoperative manipulation in cancer and other lesions of the pancreas with intraoperative ultrasound allows me to make a positive comment. But that is not the reason I rise.

You talked about the complication, a rather difficult one, of prolonged gastric atony. It seems to me that if there is a high incidence of this, you should consider the use of the new types of tubes where you can suck out the material in the stomach and at the same time give early small intestinal feeding.

Recently in our quality assurance program, we have reviewed the problems related to hyperalimentation. We have found an inordinate number of complications following the use of hyperalimentation as well as increased cost.

I would ask you, Dr. Leffall, to comment on the more routine use of this type of postoperative gastric decompression and jejunal feeding at an early time.

DR. ISIDORE COHN, JR. (New Orleans, Louisiana): I woul
congratulate Dr. Leffall for bringing into current surgical pe
the use of intraoperative radiotherapy for carcinoma of the
During the ten years that I had direction of the NCI's National
atic Cancer Project, we were looking, as was everyone else,
new method of controlling the disastrous disease that pancreat
is, and, obviously, one of the things we were thinking about a
to evaluate was the true place of this particular modality.

Dr. Leffall's co-author, Dr. Goldson, a very bright, young
sive, and enthusiastic radiotherapist, talked to us on several
about the results of this form of therapy, and we were never a
any one of the surgeons to tell us what they really thought a
think that now, with the review that we have heard this mor
have some better perspective of what the true place is of this p
modality related to pancreatic cancer.

I think that, while we need to continue to evaluate it, we
evaluate intraoperative radiotherapy against the background
we have heard this morning and what its real place might be
that is very important from a surgical standpoint.

DR. LASALLE D. LEFFALL, JR. (Closing discussion): First,
like to thank the fellows of the Southern Surgical Associatio
many letters, telegrams, and telephone calls I received last y
gaining admission to the Association. These acts of friendship
poignant reminders of what membership in this organizatio
sents. I would like to thank all of the discussants for their rem
will try to answer the questions that have been asked.

Dr. Horsley asked about the role of intraoperative therapy p
tive resection. Shelton, one of the real problems with that is n
We just don't have enough numbers to treat comparable gro
resection alone and with resection plus intraoperative x-ray t
will tell you what we do at Howard. All patients with resectab
and pancreatic cancer have potentially curative resections per
Even if all gross tumor is removed, we give adjuvant intrao
radiation therapy. The only trouble with this approach is that
measure whether it is effective or not. You can never come b
and see whether you did anything. So that is the problem you h
that.

Dr. Zeppa asked me a question as I sat down. What ab
needle aspiration biopsy? We have not used it. That is all I can
use it for breast cancer. Maybe we should begin using aspiratio
for cancer of the head of the pancreas. We have just not don
have either used the transduodenal tru-cut needle core biopsy
is unsuccessful, a wedge biopsy.

I want to thank Dr. Shumacker for his kind and thought
ments. There is no question that treatment with systemic hy
mia has been in the domain of the charlatan, as much as in the
of clinicians who have been trying to do something to trea
effectively. Further study of intraoperative hyperthermia and r
therapy is needed.

In terms of the question that Dr. Martin asked me, is intrao
radiation therapy still justifiable? We look with interest at w
are doing at the Mayo Clinic, even though Dr. Martin is now
my home-state of Florida, at Jacksonville, Mayo Clinic South.
still interested in their results because they have significant n
and we want to know whether they have shown any improve
the management of patients with nonresectable cancers of t
creas. Do we still think it is justifiable? Not in the ways it has b
in the past. That is the reason we have chosen to go with IO
intraoperative hyperthermia.

Dr. Nyhus, we have used enteral and parenteral hyperalim
very liberally. I know your question came from a disintereste
ased party, and that I understand. We do use the feeding jejun
but perhaps we do need to be a bit more aggressive in what we
as feeding tubes are concerned.

Finally, I would like to thank Dr. Isidore Cohn for his grea
us in the early phases of our work, when he was in charg
pancreatic cancer program funded by NIH.

Now,

FOR MIXED AEROBIC/

TA

ANTI

INSTEAD
OF CONVENTIONAL
HIT-OR-MISS
THERAPY...

Targets clinically important aerobes and anaerobes†

UNASYN® (ampicillin sodium/sulbactam sodium) offers a new level of confidence in in vitro coverage of the pathogens of concern in mixed infections.

ANAEROBES "The activity [of UNASYN®] against all strains tested [272 anaerobes] was higher than that of any other drug tested; 99.6% were inhibited by [UNASYN at breakpoint]."[1]

Percent of anaerobes susceptible at breakpoint[‡§1]

UNASYN	99.6%
CHLORAMPHENICOL	98.9%
METRONIDAZOLE	96.6%
CLINDAMYCIN	80.0%

In another comparative in vitro study, UNASYN "...was far more active than any of the cephalosporins tested against the *B. fragilis* group."[2]

Percent of ***B. fragilis*** group isolates susceptible at breakpoint[‖2]

UNASYN (n = 101)	99%
CEFOXITIN (n = 98)	57%
CEFOTETAN (n = 96)	55%
CEFTIZOXIME (n = 101)	83%

ROERIG *Pfizer*
A division of Pfizer Pharmaceuticals

Please see brief summary of UNASYN® (ampicillin sodium/sulbactam sodium) prescribing information on last page of this advertisement.

[illegible] INVOLVING β-LACTAMASE-PRODUCING PATHOGENS

RGETED

BIOTIC POWER

AEROBES UNASYN provides powerful in vitro activity against virtually all aerobic cocci.

Percent of aerobes susceptible at breakpoint[||]

Staphylococcus aureus (n = 118)	**93%**
S. epidermidis (n = 127)	**98%**
Enterococci[¶] (n = 86)	**98%**
Misc. streptococci[¶] (n = 57)	**91%**

In vitro studies have also demonstrated the susceptibility of *S. saprophyticus*, *S. viridans*, *Streptococcus pneumoniae*, and *S. pyogenes* to UNASYN.

UNASYN also possesses a practical spectrum of gram-negative activity, which includes pathogens such as ***Escherichia coli*** and ***Proteus mirabilis***.

[†] In vitro susceptibility does not necessarily imply a correlation with in vivo results.

[‡] Breakpoints listed in prescribing information: UNASYN, 16 μg/mL (reported as ampicillin concentration); metronidazole, 16 μg/mL; clindamycin, 4.8 μg/mL. Estimated breakpoint for chloramphenicol based on clinical experience, 16 μg/mL.

[§] Strains used and number of isolates tested were: *Bacteroides fragilis* group, 70; pigmented *Bacteroides* group, 22; other *Bacteroides* sp, 46; *Fusobacterium* sp, 32; *Clostridium difficile*, 19; other *Clostridium* sp, 33; nonsporeforming gram-positive rods, 23; gram-positive cocci, 36.

[||] Susceptibility breakpoints used: UNASYN, 16 μg/mL (expressed as ampicillin concentration); cefoxitin, cefotetan, and ceftizoxime, ≤32 μg/mL.

[¶] These non-β-lactamase-producing strains are susceptible to ampicillin alone.

Unasyn® IM IV

(ampicillin sodium/sulbactam sodium)

On target in mixed infection*

*Due to susceptible strains of indicated organisms.

Unasyn® IM IV
(ampicillin sodium/sulbactam sodium)

1.5 to 3g q6h

BRIEF SUMMARY

UNASYN® (ampicillin sodium/sulbactam sodium) IM/IV

INDICATIONS AND USAGE

UNASYN is indicated for the treatment of infections due to susceptible strains of the designated microorganisms in the conditions listed below.

Skin and Skin Structure Infections caused by beta-lactamase producing strains of *Staphylococcus aureus, Escherichia coli,* Klebsiella* spp.* (including *K. pneumoniae*), Proteus mirabilis,* Bacteroides fragilis,* Enterobacter* spp.,* and *Acinetobacter calcoaceticus.**

Intra-Abdominal Infections caused by beta-lactamase producing strains of *Escherichia coli, Klebsiella* spp. (including *K. pneumoniae*), Bacteroides* spp. (including *B. fragilis*), and *Enterobacter* spp.*

Gynecological Infections caused by beta-lactamase producing strains of *Escherichia coli,** and *Bacteroides* spp.* (including *B. fragilis**).

*Efficacy for this organism in this organ system was studied in fewer than 10 infections.

While UNASYN is indicated only for the conditions listed above, infections caused by ampicillin-susceptible organisms are also amenable to treatment with UNASYN due to its ampicillin content. Therefore, mixed infections caused by ampicillin-susceptible organisms and beta-lactamase producing organisms susceptible to UNASYN should not require the addition of another antibiotic.

CONTRAINDICATIONS

The use of UNASYN is contraindicated in individuals with a history of hypersensitivity reactions to any of the penicillins.

WARNINGS

SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (ANAPHYLACTIC) REACTIONS HAVE BEEN REPORTED IN PATIENTS ON PENICILLIN THERAPY. THESE REACTIONS ARE MORE APT TO OCCUR IN INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY AND/OR HYPERSENSITIVITY REACTIONS TO MULTIPLE ALLERGENS. THERE HAVE BEEN REPORTS OF INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE REACTIONS WHEN TREATED WITH CEPHALOSPORINS. BEFORE THERAPY WITH A PENICILLIN, CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION OCCURS, UNASYN SHOULD BE DISCONTINUED AND THE APPROPRIATE THERAPY INSTITUTED.

SERIOUS ANAPHYLACTOID REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

PRECAUTIONS

General: A high percentage of patients with mononucleosis who receive ampicillin develop a skin rash. Thus, ampicillin class antibiotics should not be administered to patients with mononucleosis. In patients treated with UNASYN the possibility of superinfections with mycotic or bacterial pathogens should be kept in mind during therapy. If superinfections occur (usually involving *Pseudomonas* or *Candida*), the drug should be discontinued and/or appropriate therapy instituted.

Drug Interactions: Probenecid decreases the renal tubular secretion of ampicillin and sulbactam. Concurrent use of probenecid with UNASYN may result in increased and prolonged blood levels of ampicillin and sulbactam. The concurrent administration of allopurinol and ampicillin increases substantially the incidence of rashes in patients receiving both drugs as compared to patients receiving ampicillin alone. It is not known whether this potentiation of ampicillin rashes is due to allopurinol or the hyperuricemia present in these patients. There are no data with UNASYN and allopurinol administered concurrently. UNASYN and aminoglycosides should not be reconstituted together due to the *in vitro* inactivation of aminoglycosides by the ampicillin component of UNASYN.

Drug/Laboratory Test Interactions: Administration of UNASYN will result in high urine concentration of ampicillin. High urine concentrations of ampicillin may result in false positive reactions when testing for the presence of glucose in urine using Clinitest™, Benedict's Solution or Fehling's Solution. It is recommended that glucose tests based on enzymatic glucose oxidase reactions (such as Clinistix™ or Testape™) be used. Following administration of ampicillin to pregnant women, a transient decrease in plasma concentration of total conjugated estriol, estriolglucuronide, conjugated estrone and estradiol has been noted. This effect may also occur with UNASYN.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Long-term studies in animals have not been performed to evaluate carcinogenic or mutagenic potential.

Pregnancy

Pregnancy Category B: Reproduction studies have been performed in mice, rats, and rabbits at doses up to ten (10) times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to UNASYN. There are, however, no adequate and well controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed. (See—Drug/Laboratory Test Interactions.)

Labor and Delivery: Studies in guinea pigs have shown that intravenous administration of ampicillin decreased the uterine tone, frequency of contractions, height of contractions, and duration of contractions. However, it is not known whether the use of UNASYN in humans during labor or delivery has immediate or delayed adverse effects on the fetus, prolongs the duration of labor, or increases the likelihood that forceps delivery or other obstetrical intervention or resuscitation of the newborn will be necessary.

Nursing Mothers: Low concentrations of ampicillin and sulbactam are excreted in the milk; therefore, caution should be exercised when UNASYN is administered to a nursing woman.

Pediatric Use: The efficacy and safety of UNASYN have not been established in infants and children under the age of 12.

ADVERSE REACTIONS

UNASYN is generally well tolerated. The following adverse reactions have been reported.

Local Adverse Reactions

Pain at IM injection site—16%
Pain at IV injection site—3%
Thrombophlebitis—3%

Systemic Adverse Reactions

The most frequently reported adverse reactions were diarrhea in 3% of the patients and rash in less than 2% of the patients.

Additional systemic reactions reported in less than 1% of the patients were: itching, nausea, vomiting, candidiasis, fatigue, malaise, headache, chest pain, flatulence, abdominal distension, glossitis, urine retention, dysuria, edema, facial swelling, erythema, chills, tightness in throat, substernal pain, epistaxis and mucosal bleeding.

Adverse Laboratory Changes

Adverse laboratory changes without regard to drug relationship that were reported during clinical trials were:

Hepatic: Increased AST (SGOT), ALT (SGPT), alkaline phosphatase, and LDH.
Hematologic: Decreased hemoglobin, hematocrit, RBC, WBC, neutrophils, lymphocytes, platelets and increased lymphocytes, monocytes, basophils, eosinophils, and platelets.
Blood Chemistry: Decreased serum albumin and total proteins.
Renal: Increased BUN and creatinine.
Urinalysis: Presence of RBC's and hyaline casts in urine.

The following adverse reactions have been reported with ampicillin-class antibiotics and can also occur with UNASYN.

Gastrointestinal: Gastritis, stomatitis, black "hairy" tongue, enterocolitis and pseudomembranous colitis.

Hypersensitivity Reactions: Urticaria, erythema multiforme, and an occasional case of exfoliative dermatitis have been reported. These reactions may be controlled with antihistamines and, if necessary, systemic corticosteroids. Whenever such reactions occur, the drug should be discontinued, unless the opinion of the physician dictates otherwise. Serious and occasional fatal hypersensitivity (anaphylactic) reactions can occur with a penicillin (see WARNINGS).

Hematologic: In addition to the adverse laboratory changes listed above for UNASYN, agranulocytosis has been reported during therapy with penicillins. All of these reactions are usually reversible on discontinuation of therapy and are believed to be hypersensitivity phenomena.

Totally current data and opinion on surgical management of colorectal cancers

Three volumes in the respected *Problems in General Surgery* series bring you up-to-the minute information that you can use *today* in your practice. Articles with real clinical relevance. Succinct presentations of major differences of opinion. Starkly different points of view on diagnosis and treatment—the questions you face when you make life-and-death decisions. The best thinking of leading practitioners to help you make the choices of modality of treatment most appropriate for each patient.

Here are information and insights that will challenge you to do something different and better in your practice the day after finishing each volume.

Abundant illustrations, diagrams, tables, charts. Totally current references, with commentary. *Each volume $30.00. Annual subscription (4 volumes) $59.00 (U.S.), $68.00 (elsewhere).*

Send for the volumes you need today. And begin your subscription to this challenging series with the next volume.

Vaterian Cancer in Siblings

JOHN C. AUSTIN, M.D., CLAUDE H. ORGAN, JR., M.D., F.A.C.S., G. RAINEY WILLIAMS, M.D., F.A.C.S.,
and JAN V. PITHA, M.D., PH.D.

From the Departments of Surgery and Pathology,
University of Oklahoma Health Sciences Center,
Oklahoma City, Oklahoma

The simultaneous occurrence of Vaterian carcinoma in two siblings suggests a genetic influence in their pathogenesis. Their classic clinical presentation of obstructive jaundice and weight loss required pancreaticoduodenectomy for this neoplasm. Pedigree analysis revealed a third sibling who died from an unresectable periampullary malignancy. Neither of the probands exhibited, as late as the seventh decade, evidence compatible with a diagnosis of familial polyposis coli or Gardner's syndrome. Flow cytometry studies revealed an aneuploid distribution in one tumor and tetraploid in the other. The rarity of this neoplasm, in the absence of contributing epidemiologic factors, suggests that this is a pleotrophic manifestation of a cancer-prone genotype.

CARCINOMA of the ampulla of Vater, a rare tumor of the duodenum, constitutes 0.01% of solid tumor cases and is found in 0.2% of postmortem examinations.[1] The overwhelming number of malignant ampullomas appear sporadically in the population and are considered to be multifactorial in origin and nonheritable. A previous report presented to this association in 1976[2] discussed the association of periampullary malignancies, Gardner's syndrome (GS), and familial polyposis coli (FPC). The simultaneous occurrence of this rare duodenal neoplasm in sibling males suggests a genetic influence on pathogenesis.

Case Reports

Case 1. A 66-year-old man presented to the hospital with a 3-week history of painless jaundice, dark urine, and a 6-month weight loss of 15 lb. He denied any previous history of hepatitis or pancreatitis, although a single-unit blood transfusion was received during an uncomplicated cholecystectomy 15 years prior to admission for cholelithiasis.

Past medical history was unremarkable except for moderate controlled hypertension. Medications included clonidine and a tricyclic antidepressant. Physical examination demonstrated a deeply jaundiced, emaciated man. Except for an enlarged liver, abdominal examination was unremarkable for tenderness or palpable masses.

Abnormal laboratory data included a total bilirubin of 15.5 mg/dL, alkaline phosphatase of 575 U/L, and an SGOT of 213 U/L (Table 1). Computed axial tomography (CAT) of the abdomen revealed a cystic mass in the head of the pancreas, dilated intrahepatic and extrahepatic bile ducts, and no significant periaortic lymph node enlargement (Fig. 1). Percutaneous transhepatic cholangiography confirmed the presence of gallstones plus intrahepatic and extrahepatic biliary duct dilatation secondary to a distal common duct obstruction. Diffuse enlargement of the pancreatic duct was demonstrated on endoscopic retrograde cholangiopancreatography (Fig. 1). Biopsy of a friable mass at the ampulla of Vater proved to be adenocarcinoma on frozen section.

At laparotomy a small mass was present in the head of the pancreas with no evidence of hepatic or lymph node metastases. Pancreaticoduodenectomy was performed uneventfully. The presence of a 2-cm ampullary adenocarcinoma was confirmed on microscopic examination; ten identifiable lymph nodes were free of tumor (Fig. 2). The patient was discharged on the 16th postoperative day following an uncomplicated course. Subsequent colonoscopy and barium enema, performed because of concern that the lesion might be associated with FPC, were both within normal limits with no evidence of gastrointestinal polyps. At 16 months there were no signs or symptoms of recurrent disease with normal nutrition. The patient expired 30 months after the operation. Postmortem examination was not obtained.

Case 2. A 64-year-old brother of Case 1 had always been in good health. Two weeks after his brother's operation he was admitted with similar symptoms, *i.e.,* a 2-month history of painless jaundice, dark urine, and a 22-lb weight loss. Hepatitis profile was HAV antibody and Hb core antibody positive; Hb surface antigen and IgM were negative (Table 1). There had been no previous serious illnesses, operations, or hospitalizations. On physical examination he was emaciated and icteric. Abdominal examination revealed an enlarged liver 12–13 cm wide at the midclavicular line. Abnormal laboratory values included a total bilirubin of 9.4 mg/dL, alkaline phosphatase of 410 U/L, SGOT of 239 U/L, and guaiac-positive stools (Table 1).

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests and correspondence: Claude H. Organ, Jr., M.D., University of Oklahoma Health Sciences Center, Department of Surgery, P.O. Box 26307, Oklahoma City, OK 73126.

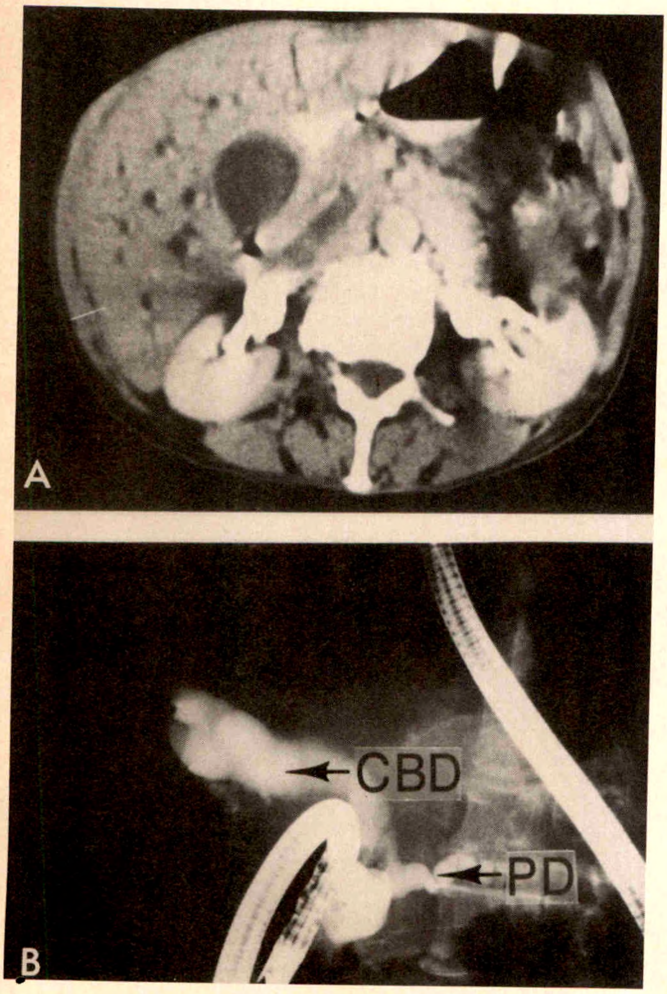
Submitted for publication: December 10, 1987.

TABLE 1. *Laboratory Determinations*

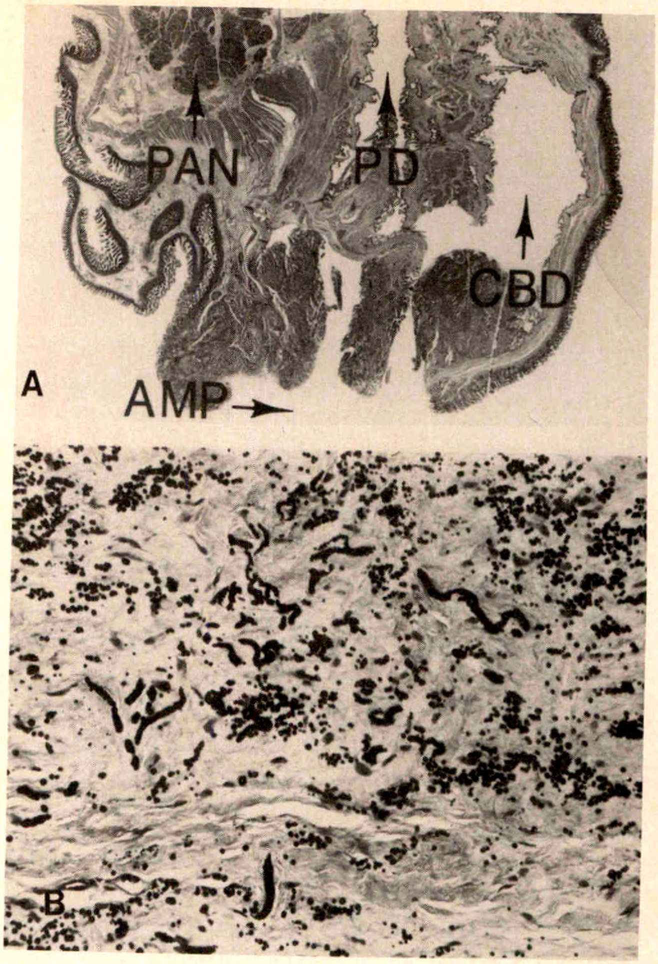
	Case 1	Case 2
Serum bilirubin	15.5	9.4
Alkaline phosphatase	575	410
SGOT	213	239
HAV antibody	Negative	Positive
Hb core antibody	Negative	Positive
Hb surface antibody	Negative	Negative
IgM	Negative	Negative

Ultrasonography of the pancreas and biliary tree demonstrated dilated intrahepatic and extrahepatic biliary ducts without evidence of cholelithiasis. An abdominal CT scan revealed no evidence of a pancreatic mass or periaortic–pericaval lymphadenopathy. On ERCP a friable fungating mass was observed at the ampulla of Vater and a dilated pancreatic duct was demonstrated (Fig. 3). Biopsy of the mass was compatible on light microscopy with a diagnosis of an infiltrating, moderately well-differentiated Vaterian adenocarcinoma (Fig. 4).

Following 1 week of hyperalimentation a successful pancreaticoduodenectomy was performed. Histologic examination of the specimen revealed a 4-cm malignant ampullary adenocarcinoma; two of seven lymph nodes were positive for tumor. The immediate postoperative period was complicated by bilateral lower lobe pneumonia. The patient was discharged 1 month following the procedure. Case 2 was free from disease for approximately 1 year after operation when CAT scan confirmed the presence of hepatic and regional metastases. A moderate objective response was observed with 5-fluorouracil (5-FU) therapy. The patient died 18 months after surgery with extensive recurrent intra-abdominal disease. Postmortem examination was not obtained. Case 2, whose tumor was large and infiltrating with metastatic lymph nodes, exhibited biologic aggressiveness. In comparison the tumor in Case 1 was small without lymph node involvement and was less aggressive.



FIGS. 1A and B. *A.* CAT of Case 1. *B.* ERCP of Patient 1. CBD = common bile duct; PD = pancreatic duct.



FIGS. 2A and B. Photomicrographs of Case 1. PAN = pancreas; AMP = ampulla of Vater. (A): original magnification by 2.5. (B): original magnification by 10.

Chromosome analysis of both patients demonstrated no morphologic abnormality in either patient with conventional G-banding, C-banding, and karyotypes. HLA typing failed to reveal any significant correlation between these siblings: HLA typing on Case 1 was A11, A33, B8, DR1, DR7; while Case 2 was A2, A3, B44, D35, DR1, and DR5 (Table 2).

Flow cytometry studies were performed to determine ploidy distribution in deparaffinized tissue specimens. Flow cytometric DNA analysis of cell nuclei stained with propidium iodide revealed two normal DNA distributions including normal percentages of cells in both G0–G1 and G2–M phases. Two other DNA distributions were identified as abnormal: one exhibited a hypodiploid distribution of cells included in the G0–G1 phase and the other exhibited a tetraploid distribution of cells. Peak channels for the cells in the DNA distribution are as follows: the normal DNA distributions were from normal tissue; the abnormal DNA distributions (tetraploidy) represented malignant tissue.

An outline of this kindred presented in Figure 5 reveals a younger sister who had an exploratory laparotomy at another hospital in 1979. The operative findings were compatible with a periampullary neoplasm, although it was not possible to determine the specific site of origin. Intraoperative biopsy of a liver nodule confirmed the presence of metastatic cancer. Investigation of other available siblings revealed evidence of an occasional gastrointestinal polyp but no evidence of FPC.

Discussion

The presence of ampullary carcinoma in two male siblings simultaneously presenting within 2 weeks of each other in their seventh decade, and the identification of a third sibling deceased from a periampullary malignancy, suggests a phenotypic expression of a deleterious gene and not a chance occurrence. The odds against two siblings out of 11 developing pancreatic cancer in the same year, in the absence of a genetic factor, is 100,000,000:1. Cancer of the ampulla of Vater is even more rare, and the odds are even greater against two siblings developing the disease. Previous authors have associated periampullary cancer with FPC and GS.[3–6]

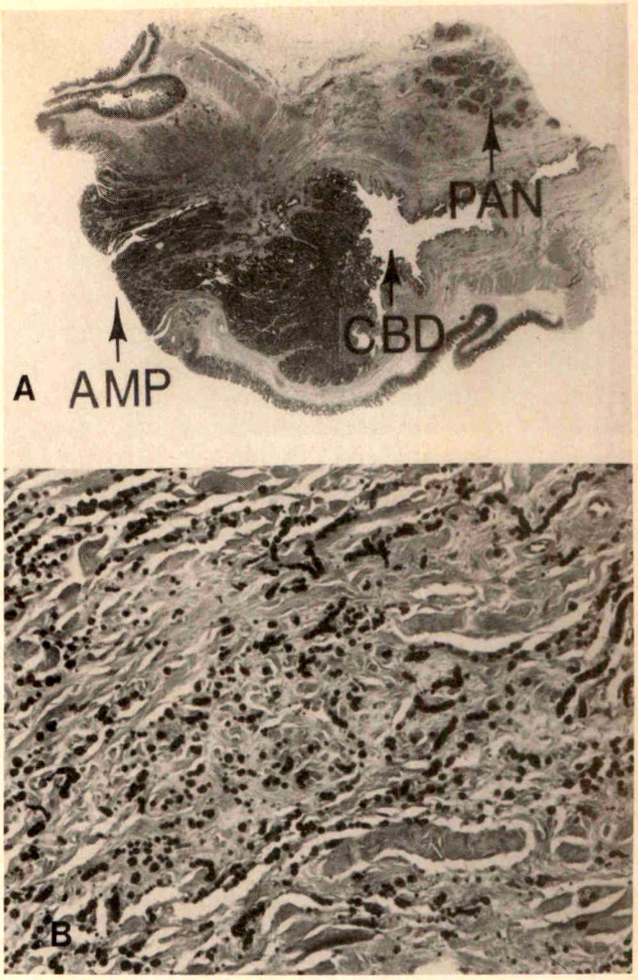

FIGS. 4A and B. Photomicrographs of Case 2. PAN = pancreas; AMP = ampulla of Vater. (A): original magnification by 2.5. (B): original magnification by 10.

Vaterian cancer, like other malignancies with limited numbers available for study, has not undergone careful epidemiologic review. The influence of genetics on this neoplasm has been given little attention with regard to its pathogenesis. Geneticists understandably have concentrated their studies on unifactorial disorders that occur more frequently in the population. This neoplasm, in the absence of an identifiable single-gene determined etiology, should be considered multifactorial in origin. Such multifactorial disorders are presumed to result largely from the additive effect of a number of factors, some genetic and others environmental.[7] A variety of aneuploid states, single-gene disorders, and other

TABLE 2. *HLA Typing*

Case 1	Case 2
A11 A33 B8 DR1 DR7	A2 A3 B44 D35 DR1 DR5

polygenic conditions may predispose to malignancy, although the exact molecular mechanisms are rarely clear. The complexity and importance of host factors in such tumors become increasingly important and are very difficult to discern.

The most attractive hypothesis for the simultaneous occurrence of this unusual phenomenon is that it is a variant of FPC or GS. It is difficult for the surgeon and pathologist to differentiate between carcinoma arising from the mucosa of the second part of the duodenum, the ampulla of Vater, and the intramural segments of the common bile and pancreatic ducts. Periampullary carcinoma has been described in approximately 30 patients with GS and is recognized as more than a chance occurrence in this syndrome.[2–5] The wide spectrum of extracolonic manifestations identified with GS reflects the variability of gene penetrance. Whether or not a familial occurrence can be implicated in ampullary carcinoma without colonic polypoid disease is conjectural. Neither of these siblings demonstrated colonic or other manifestations of GS as evidenced by normal physical examination, barium enema, and skeletal survey.

The familial aggregation of site-specific neoplasms should be confirmed by pedigree analyses. Of the 11 siblings in this kindred, the two probands and the younger sister discussed in this report died of ampullary or periampullary cancer. Four of the remaining eight have expired of cirrhosis, diphtheria, blood poisoning, and a cerebrovascular accident. Only one of the four living siblings has exhibited interest and agreed to a screening and follow-up studies. One proband worked in a flour mill and the other was a crane operator. No significant environmental or unusual lifestyle circumstances were discoverable from interviews with multiple family members; hence this unique occurrence cannot be accounted for by any known environmental factors.

In the cancer family syndrome a pattern of malignancies emerges, although every individual does not necessarily have the same neoplasm. Familial tumors share several cardinal features: (1) they tend to occur at an earlier age, often 12–15 years before sporadic cases appear; (2) there is an increased incidence of synchronous and metachronous lesions; (3) they may be multicentric and/or bilateral where paired organs exist; (4) there is an excess of 25% of the family members affected who are in direct lineal descent from the proband; and (5) the cancer predisposition in these families behaves as an autosomal dominant trait with a 60% or more penetrance.

There are several possible explanations for the phenotypic expression of Vaterian cancer in these male siblings. The tumors in this family may be due to: (1) chance alone, although this is unlikely; (2) the late penetrance of a GS genotype; (3) tumor heterogeneity caused by a different allele at the same locus; or (4) a pleiotropic manifestation of a cancer-prone genotype being expressed as a result of environmental changes.[6]

In 1935 Cabot[3] described a 36-year-old man (Case No. 21061 from the Massachusetts General Hospital) with weakness, diarrhea, ankle edema, and jaundice

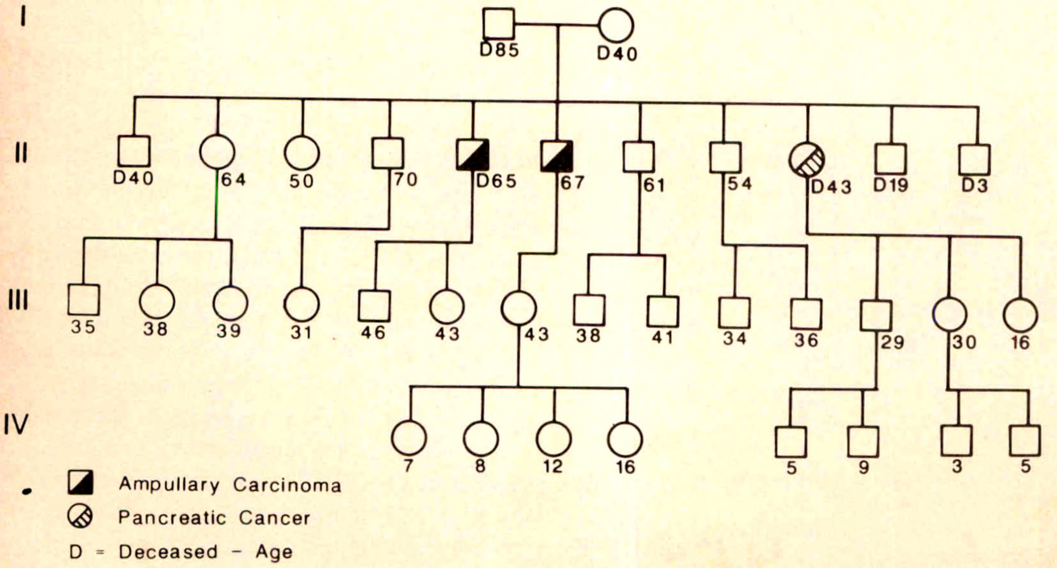

FIG. 5. An outline of kindred for Cases 1 and 2.

who had several manifestations of GS (Table 3). At abdominal exploration for obstructive jaundice he was found to have an ampullary cancer and multiple intestinal polyps. No segment of the gastrointestinal tract greater than 3 cm in length was uninvolved with polyps. Bony exostosis existed in this deformed male with a prior history of having several hard masses removed from the skull, ribs, and mandible. He also had a previously resected fibrosarcoma. His grandmother died of carcinoma (site unknown) and his mother of rectal carcinoma at age 34. Multiple members of the family (mostly females) and their offspring for three previous generations were afflicted with similar bony growths.

Macdonald et al.[4] in 1967 reported two cases associating GS with FPC and periampullary malignancies. Both patients had clinical evidence of FPC and GS. However, one of the periampullary malignancies was located in the head of the pancreas and the other in the ampulla of Vater. One patient had an associated renal adenoma and the other a papillary duodenal adenoma at some distance from the ampulla.

Watne et al.[5] in 1975 reported 11 families with GS involving 280 patients. Two associated cases of Vaterian cancer, one malignancy in the liver and one in the pancreas, were present in these cohorts. However, in 41 cases intestinal cancer developed, often appearing at an earlier age for each successive generation.

Nance and Jones[2] in 1977 reported three females with carcinoma of the ampulla of Vater, all of whom had FPC. Two of their cases were from the same kindred. All of their patients fulfilled the criteria of Morson and Bussey[8] for the diagnosis of FPC; however, none expressed the classic features of GS as they are currently known. They postulated that GS should be viewed as an extracolonic variant of FPC and not as a separate disease process. They also concluded that the FPC patient having extracolonic lesions was an example of GS.

Lynch et al.[6] in 1985 reported a family study of pancreatic carcinoma and hereditary nonpolyposis colorectal cancer. This kindred exhibited vertical transmission of cancer through five generations with a high frequency of associated hereditary nonpolyposis colorectal cancer. They appropriately suggested a need for more biomarker and pedigree studies with better documentation of cancer at all sites.

Several factors mitigate against the diagnosis of GS in the cohort group: no polyps; the absence of extracolonic manifestations of FPC; the absence of metachronous or synchronous lesions; and no instances in this family up to the present time of osteomas, soft tissue tumors, dental anomalies, thyroid cancer, ovarian or carcinoid tumors, lymphoma, fibrosarcoma, brain tumor, skin pigmentation, or FPC.[2,9-11]

In tumors that are heritable, two mutation events are required, the initial one being germinal and the second somatic.[7] Nonfamilial tumors tend to be unifocal and appear at a later age because two distinct somatic events would be required for tumor development. Implicit in this two-hit hypothesis is the assumption that carcinogenesis is related to discrete random changes occurring at a constant average rate. The occurrence of these ampullomas in the seventh decade in male siblings would presently be better placed in the nonfamilial category until such time as there is greater penetrance and expressivity to suggest a diagnosis of GS or FPC.

TABLE 3. *Study Comparison*

Author	Year	Age (yr)/Sex	Site	FPC	GS

		64/M†	AV	No	No

* Same kindred.
† Same kindred.
AV = ampulla of Vater.
PH = pancreatic head.
HNPCC = hereditary nonpolyposis colorectal cancer.

Of the 12 cases reviewed in this communication with the association of Vaterian carcinoma, FPC, and GS,[3-6] three of the tumors were periampullary (25%), not specifically Vaterian in origin (Table 4). Confirmed FPC was reported in nine cases (75%) and in a single case of hereditary nonpolyposis colorectal cancer. Six of the 12 cases (50%) met reasonable criteria for a diagnosis of GS. If the assumptions of Jones and Nance[2] are valid, these numbers would then increase to nine of 12 (75%). No specific trend in morphologic categorization using the criteria outlined by Blumgart and Kennedy[1] could be ascertained. The nine ampullomas, according to this categorization would be as follows: Type I, three; Type II, two; and Type III, four. HLA typing when compared with matched controls demonstrated no difference.

TABLE 4. *Association of FPC, GS, and Vaterian carcinoma in 12 patients*
n = 12

	PH	AV	Yes	No
Site	25%	75%	—	—
FPC	—	—	75%	25%
GS	—	—	50%	50%

PH = pancreatic head.

Genetic counseling and screening for these families is important to reduce their obvious hidden family anxiety. In the absence of a specific biomarker(s), the accuracy of the pedigree analysis becomes increasingly important requiring histologic confirmation of the disease(s) existing in this kindred. Where biochemical markers exist they must be obtained and repeated as part of the follow-up process. Syndromes such as FPC and GS seldom present all of their classic features when initially discovered. The unfolding and phenotypic expressions among these cohorts require close monitoring. The importance of this familial or hereditary pattern of tumor distribution is emphasized by the recent report of their improved survival.[12]

DISCUSSION

DR. ALVIN L. WATNE (Peoria, Illinois): First, I want to extend my welcome to Claude and Betty on their membership in the Association.

I want to congratulate the authors on what I think is a very important observation. Opportunity comes to those who have an alert mind and make a critical observation, and I want to thank them for sharing their manuscript with me. I took the liberty to bring along a few slides. I've assured Claude that I would not have a 29-page discussion.

(Slide) The question came up about the relation to Gardner's Syndrome. Both Gardner himself and our group now feel that Gardner's Syndrome is probably the ultimate manifestation of the inherited characteristic. As you can see, 60% had soft tissue tumors, 30% had bony tumors, and two-thirds of them showed polyps, so we had patients with soft tissue tumors and no polyps. We had patients with polyps and no soft tissue tumors.

(Slide) Here is this broad group of manifestation of tumors that show up in this syndrome that Dr. Organ referred to, and you will notice that two of our patients had carcinoma of ampulla of Vater.

Dr. Julian Ambrose took a look at this group of patients, and he said, "It looks like you were feeding them a carcinogen." The patients with carcinoma of the ampulla of Vater had no other manifestations of Gardner's Syndrome. However, relatives in their families did show the syndrome.

(Slide) One of these patients was particularly interesting. This 18-year-old girl entered our hospital in 1973 with (by history and physical examination) an obvious carcinoma of the ampulla of Vater.

Her colon had been removed for polyps 2 years previously. She underwent a decompression cholecystojejunostomy, and, at that time, we could palpate a small tumor at the ligament of Treitz. After about an 8-week period, she then underwent a pancreaticoduodenectomy, including the gallbladder and the cholecystojejunostomy, and during that interval of about two months, she had developed another adenomatous polyp right at the cholecystojejunostomy.

(Slide) In 1978, this girl developed a cyst-adenocarcinoma of the ovary, and in 1982, we removed her rectal segment for three carcinomas that had developed despite repeated proctoscopic examination; so this girl manifested three different malignant neoplasms in her life.

(Slide) That brought us to study any associated inherited characteristics, and in our patients we found that there was a marked increase in the cholesterol fraction and the primary bile acid fraction in the fetal steroids of patients with polyposis coli or Gardner's syndrome.

We have also recently seen that there is an increase in the glycosyl transferase activity and a decrease in the glycoprotein formed in the colonic mucosal cell wall of these patients.

(Slide) One last point that will lead to a question: These patients have been shown by Utsunomiya to develop gastric and duodenal polyps. So I will now ask some questions of Dr. Organ, if I might.

The first question would be: Have you noticed any other physiological or biochemical changes such as alterations in fecal steroids, bile salts and increased or decreased incidence of cholelithiasis.

Have you extended your study of your patients to the cousins? You must extend that family group that you showed us because the manifestations may appear in other family members. The patients may have expired before the manifestations appeared, and the trait will show up in the next generation. Have you any data regarding the incidence of polyps of the upper gastrointestinal tract in these patients, and what would be your approach to an adenomatous polyp of the upper gastrointestinal tract in these patients?

DR. F. CARTER NANCE (Livingston, New Jersey): I enjoyed Dr. Organ's and Dr. Watne's paper and would like to give one of my own.

(Slide) Dr. Organ was kind enough to mention my study. We found a similar problem and reviewed 19 reported cases of periampullary carcinoma in patients with Gardner's Syndrome. We did stretch the diagnosis of Gardner's Syndrome, feeling that any manifestation of the familial polyposis syndrome associated with extracolonic findings should be grouped in that category.

I think the striking thing for us was that most of these patients were presented at an early age with the periampullary carcinoma.

(Slide) And another striking aspect was that the type of periampullary malignancy was ampulla of Vater in most of them—although duodenal pancreatic and undetermined.

As Dr. Watne mentioned, (Slide) our recommendations on the basis of our findings, at least, for the patients who have the marker of familial polyposis are that there be routine surveillance not only of the lower gastrointestinal tract (if any colon is left), but routine surveillance of the upper gastrointestinal tract, endoscopic biopsy removal of all duodenal and gastric polyps and surgical removal of recurrent or malignant polyps.

Unfortunately, in this group of patients that Dr. Organ has presented, there isn't a convenient marker of familial polyposis, and I guess that really raises my biggest question. Has he identified anything in these families that will allow us to identify the cohort and to do some sort of reasonable surveillance in this group of patients?

It is a beautifully studied family, but I would hope that he can extend his familial study, as Dr. Watne suggested, to identify any further members of the cohort and to identify any markers that we could use for rationale surveillance.

DR. JOHN C. MCDONALD (Shreveport, Louisiana): I was honored that Dr. Organ would ask me to discuss his first presentation as a member of this society.

This paper should be considered in the context of a series of publications by Dr. Organ on familial cancer, a subject in which he has had an abiding interest.

In the apparent effort to find some genetic marker to relate to these patients, he studied the HLA locus and found no relationship, and it is that point that I would like to discuss.

Some 20 years ago a small paper was published which seemed to show a relationship between the H2 phenotype and murine leukemia. Shortly thereafter, immune response genes were discovered and related to the major histocompatibility locus. These two observations set in motion an avalanche of studies all designed to relate some disease state to the HLA phenotype or genotype.

Some 20 years later there are at least four or five dozen such conditions well established statistically. These disease processes generally fall into two general categories. One is a series of arthropathies of which Reiter's Syndrome is a prototype, and the other is a large variety of diseases that seem to be related to autoimmunity.

It is ironic that even though the original observation was related to a malignant condition, after 20 years there is not a single human malignancy that appears to have been reliably related to the HLA locus. So while one intuitively believes that there must be a genetic marker or genetic information that is related to these familial cancer syndromes, it appears not to be HLA locus.

DR. CLAUDE H. ORGAN, JR. (Closing discussion): I wish to thank Dr. Watne and Dr. McDonald for their contribution; we relied on their work to point us in the right direction. Research giveth and research taketh away. We have been the beneficiaries since World War II of superb research in the United States and worldwide; and just as research takes procedures away from us, it affords us new opportunities. Genetics offers that opportunity for us.

It is said that the clinician or the clinical investigator is a vanishing breed, and that the basic scientists are in one part of the university and the clinicians in another. It behooves us as clinicians to become involved with these studies. I am not a geneticist, but I realize the benefits that can accrue from this. These pedigree analyses are very difficult to formulate. Again I thank Dr. Austin, one of our very talented residents who has narrowed his interest and talents down to thoracic surgery for dealing with a very difficult family that is fearful of being called a cancer family. Usually there is a family historian to be dealt with whose confidence must be gained, who has a family bible or can give you much of this information.

Dr. Watne, in the large series from Omaha that is masterminded by Dr. Henry Lynch, (glycoproteins or fecal steroids were not dealt with. At the Familial Institute they have had as one of their main areas of concentration the development of pedigree analysis. These are very hard to compile because once you get beyond first-degree relatives in our mobile society, it is difficult to obtain information from second-degree relatives.

These pedigrees have been studied with a number of enzymes and biochemical markers, recently including alpha-fucosidase.

The studies on twins with cancer have been remarkably unproductive. This genotype will be carried by a male and be phenotypically expressed in the next generation in the other sex.

This is a difficult family. We have had a difficult time getting them in, and we don't know what the G. I. tract of many of them really looks like. If polyps are high in the G. I. tract, they should be scoped often and as many of them excised endoscopically as possible. There tends to be an aboral increase in the incidence of malignancy or the propensity toward malignancy, that is, it would be lower in the stomach than in the colon. Therefore, endoscopic removal of these and endoscopic review of these on a periodic basis, alternating with barium swallow and/or enema, would be indicated.

It has certainly raised the possibility of gastric mucosectomy, a procedure that would be a little more vascular than rectal mucosectomy if you are operating on the same type of stomachs that I am.

Polyamine Levels and Gastrin Receptors in Colon Cancers

JAMES R. UPP, JR., M.D.,* RAMI SAYDJARI, M.D., COURTNEY M. TOWNSEND, JR., M.D., POMILA SINGH, PH.D., SAM C. BARRANCO, PH.D.,† and JAMES C. THOMPSON, M.D.

Polyamines and gastrin receptors (GR) were studied in samples of colon cancer and mucosa from 40 patients and in control mucosa from 11 patients without cancer. Polyamines (*i.e.*, putrescine, spermidine, spermine) are essential for growth and differentiation. The concentration of polyamines is elevated in rapidly proliferating normal tissues and in some cancers. The presence of GR in human colon cancers has been previously reported. The purpose of the present study was twofold: (1) to determine whether polyamine levels are elevated in colon cancers and in adjacent normal colon mucosa compared to colon mucosa from patients without cancer; and (2) to examine the relationship between polyamine levels and GR in colon cancers. Polyamine levels in colon cancers were significantly higher than in the normal colon mucosa from the same patients. The polyamines, spermidine and spermine, were significantly higher in colon mucosa from patients with cancer compared to patients without cancer. Spermidine and the spermidine:spermine ratio, an index of cell proliferation, were increased in colon cancers with GR compared to cancers without GR. There were no significant correlations between polyamine levels and the following: patient age, CEA level, site of cancer, stage, or differentiation. Because polyamine levels are increased in colon mucosa from patients with cancer, measurement of polyamines may detect patients at risk for subsequent development of colon cancer. Increased levels of polyamines in colon cancers with GR is evidence that gastrin may play a trophic role in human colon cancers.

From the Department of Surgery, University of Texas Medical Branch, Galveston, Texas

THE POLYAMINES, putrescine, spermidine, and spermine, are small polycations that are essential for the growth of both normal and neoplastic cells.[1] Increased cellular levels of ornithine decarboxylase, the rate-limiting enzyme of polyamine biosynthesis, as well as increased levels of polyamines, occur during cellular differentiation and growth.[1,2] Concentrations of polyamines are elevated in some cancer cells compared to normal cells.[1,2] Polyamines have been linked to the regulation of synthesis of DNA, RNA, and protein[2]; the mechanisms by which polyamines exert these effects are not well understood.

Stimulation of polyamine biosynthesis occurs in the intestine in response to a variety of substances and physiologic conditions. Gastrin stimulates the growth of portions of the normal gastrointestinal tract in many species, including rats[3] and mice.[4] α-Difluoromethylornithine (DFMO), an irreversible inhibitor of ornithine decarboxylase, blocks the trophic effects of gastrin on intestinal growth.[5]

Studies in rats[6] and mice[7] have demonstrated a role of increased polyamine biosynthesis in the development of colon cancers during chemical carcinogenesis. Growth regulation of colorectal cancers that contain high levels of putrescine, spermidine, or spermine may be polyamine-dependent. Such cancers might be successfully treated with polyamine biosynthesis inhibitors. It has been previously reported that DFMO inhibited growth of the MC-26 mouse colon cancer *in vivo* and *in vitro*,[8] and inhibited growth of two human colon cancers growing in nude mice.[9]

The relationship between gastrointestinal hormones and their receptors in malignant cells has been recently

Submitted for publication: December 10, 1987.

reviewed.[10] It has been previously reported that normal human gastric and colonic mucosa and adenocarcinomas of the human stomach and colon contain specific gastrin receptors (GR).[11] The functional significance of GR on these human cancers is not yet clear.

Winsett et al.[4] found that treatment with pentagastrin, an analog of gastrin, enhanced growth of MC-26 mouse colon carcinoma and decreased the survival of treated mice; MC-26 colon cancer cells have specific, high-affinity GR. Beauchamp et al.[12] reported that proglumide, a GR antagonist, inhibited MC-26 colon cancer growth and prolonged survival in tumor-bearing mice. Chronic endogenous hypergastrinemia induced by antral exclusion in rats was reported by McGregor et al.[13] to significantly increase the growth of carcinogen-induced colon cancers. Growth of human colon cancers growing in nude mice[14] and in tissue culture[15] has been stimulated by gastrin.

The purpose of this study was to determine whether concentrations of polyamines are elevated in colon cancers and in adjacent normal colon mucosa in cancer patients compared to colon mucosa from patients without cancer, and to examine the relationship of polyamine levels in colon cancers to the GR content of cancers. The relationships between polyamine levels and age of patient, preoperative CEA level, site of colon carcinoma, histologic differentiation, and clinical stage of disease were also examined.

Materials and Methods

Specimens of primary colon cancers were obtained at the time of surgical resection from 40 patients treated at the authors' institution. The age of the patient and preoperative CEA level, as well as site of colon cancer, were recorded. The colon was divided into left and right sides, according to embryonic development; the right side (midgut) included the cecum, ascending colon, and transverse colon; the left colon (hindgut) included the splenic flexure, descending colon, sigmoid, and rectum.

All specimens were examined by a surgical pathology service. Immediately upon removal of the surgical specimens, portions of viable cancer and normal colon mucosa were excised for measurement of polyamine levels and GR. Frozen sections of the cancer adjacent to the excised portion were examined for confirmation of viable cancer. Normal mucosa was obtained from the margin of the resected colon; the absence of cancer at the margins was confirmed histologically. Specimens were snap-frozen in liquid nitrogen and stored until analysis.

The histologic diagnosis of colon carcinoma, the degree of differentiation, and the Astler–Coller modification of Dukes' classification of stage of disease[16] were determined by a surgical pathologist who had no knowledge of the results of GR analysis. Mucoid adenocarcinomas were classified separately because these tumors have a particularly poor prognosis even if the tumor is well differentiated and no lymph node metastases are present.[17]

Colon mucosa was obtained from 11 patients who had colon resection for non-neoplastic disease. Ten patients had colon resection for diverticulosis and one patient for a benign stricture. Specimens were examined histologically by a surgical pathologist to assure specimens were uninvolved with any inflammatory process or occult malignancy.

Polyamine Analysis

Tissue was homogenized in 4% sulfosalicylic acid (2 mL/g tissue), then incubated on ice for 30 minutes. The homogenate was then centrifuged at 10,000 g for 10 minutes. Aliquots of the supernatant remaining after centrifugation were analyzed using a Dionex 2110i high pressure ion chromatography unit (Dionex Corporation, Sunnyvale, CA). Polyamines were eluted using orthophthaldehyde at a flow rate of 36 mL/h. Putrescine was eluted with 0.167 mol/L K^+ buffer (pH 5.65). Spermidine and spermine were eluted with 0.66 mol/L K^+ buffer (pH 5.65). Polyamine concentrations were expressed as nmol/mg of protein. Protein content was determined by the method of Lowry et al.[18]

GR Analysis

The content of GR of the colon cancer and normal mucosal specimens were determined by methods previously described.[11] Briefly, specimens were excised and washed in ice-cold buffer A (TRIS 10 mmol/L; NaCl 137 mmol/L; KCl 5 mmol/L; CaCl 2 mmol/L; MgCl 2.5 mmol/L; and sucrose 0.25 mmol/L at a pH of 7.4), containing 0.1% bovine serum albumin (BSA, fraction V from Sigma) and then snap-frozen in liquid nitrogen and stored at −70 C. Frozen tissues were weighed and pulverized with a thermovac autopulverizer cooled in liquid nitrogen. The resulting powder was homogenized in 5 volumes of buffer A plus BSA, using a precooled polytron homogenizer (PG-10ST, Brinkman Industries, Westbury, NY). The homogenate was filtered through a double layer of cheese cloth, presoaked in ice-cold buffer A, and subjected to 200 g for 10 minutes of centrifugation to remove any cell debris. For the preparation of total crude membrane fractions, the resulting supernatant was subjected to 30,000 g for 45 minutes centrifugation in a fixed angle SM-24 rotor. The resulting pellets were then washed once again with buffer A plus BSA and repelleted at 30,000 g for 45 minutes. The pellet

TABLE 1. *Polyamine Levels (nmol/mg protein) in Left- and Right-sided Colon Cancers*

	Left (N = 25)	Right (N= 15)
Putrescine	1.33 ± 0.48	1.00 ± 0.08
Spermidine	4.50 ± 0.49	4.46 ± 0.74
Spermine	5.84 ± 0.47	5.67 ± 0.55
Spermidine:spermine ratio	0.76 ± 0.04	0.81 ± 0.08

obtained was resuspended in a buffer B (HEPES 25 mmol/L; MgCl 2.5 mmol/L; KCl 5 mmol/L; NaCl 137 mmol/L; $NHPO_4$ 0.7 mmol/L; glucose 10 mmol/L, pH 7.4) plus BSA, homogenized manually with a glass teflon homogenizer and processed for measurement of protein[18] and GR.

Synthetic human gastrin-17-I (Bachem, Torrance, CA) was iodinated as previously described.[11] The biologic activity of iodinated gastrin molecules is similar to that of an equimolar concentration of noniodinated gastrin. Aliquots of the membrane suspension in buffer B plus BSA, containing approximately 200 μg of protein, were used as substrate in each tube. A multipoint saturation analysis (7–10 points per assay), using increasing concentrations of radiolabeled gastrin (0.01–0.05 mmol/L) with (nonspecific binding) or without (total binding) 1000-fold excess of radioinert gastrin was carried out, and the binding was analyzed by a Scatchard plot of the specific binding data. The binding assay was performed at 30 C in a water bath for 30 minutes, after which the tubes were chilled on ice and 100 μL of ice-cold buffer B plus BSA added. The peptide hormone bound to the substrate was separated from the excess unbound hormone by filtration over cellulose acetate filters using a multifiltration unit (1225 sampling manifold, Millipore). The membrane filters containing the substrate were placed in a glass tube and counted in a gamma counter (Beckman Model 5550, with 78% efficiency for iodine 125 counting).

Data Analysis

The relationship between the age of the patient or the preoperative CEA levels compared to the polyamine concentrations of colon cancers and of normal mucosa from patients with colon cancer were each examined by means of linear regression analysis. The mean putrescine, spermidine, and spermine concentrations were determined in groups of patients with cancers of different degrees of histologic differentiation and stage of disease (Stages A and B *vs.* Stages C and D). Differences between groups were analyzed by the Kruskal–Wallis test and the Mann–Whitney test. A value of $p < 0.05$ was considered significant. Polyamine levels in normal colon mucosa of cancer patients were compared to the levels in colon cancers, as well as to colon mucosa from patients without cancer, by the Kruskal–Wallis test and the Mann–Whitney test. Polyamine concentrations in cancers with high-affinity GR were compared to concentrations in cancers without GR.

The spermidine:spermine ratio[19] (an index of cell proliferation that is increased in rapidly proliferating tissues) was also compared in the different groups.

Results

Of the 40 patients with colon cancer in the study, 25 had cancers arising from the left side of the colon and 15 had cancers arising from the right side. There were no significant differences in polyamine levels between left- or right-sided cancers (Table 1). Polyamine levels of colon cancers or normal mucosa from patients with colon cancer did not correlate with patient age or with preoperative CEA level (data not shown).

Putrescine, spermidine, and the spermidine:spermine ratio were significantly increased in colon cancers compared to the colon mucosa from the same patients (Fig. 1). Spermine levels were not significantly different between colon cancers and normal colon mucosa from the cancer patients. Levels of spermidine and spermine were also increased in the normal colon mucosa from cancer patients compared to the normal colon mucosa from patients without cancer (Fig. 1).

Spermidine and spermine were both significantly elevated in the colon mucosa from cancer patients compared to the colon mucosa from patients without cancer. Spermidine was 1.78 ± 0.21 nmol/mg protein in control colon mucosa and 3.50 ± 0.37 nmol/mg protein in colon mucosa from cancer patients. Spermine was 3.50 ± 0.48 nmol/mg protein in control colon mucosa and 5.32 ± 0.32 nmol/mg protein in colon mucosa from cancer patients. The spermidine:spermine ratio of normal colon mucosa from cancer patients was increased compared to normal colon mucosa from patients without cancer (Fig. 1).

The relationship of polyamine levels in colon cancers and normal colon mucosa from cancer patients was examined by linear regression analysis (Figs. 2 and 3), and a significant correlation was found between the levels of putrescine (Fig. 2) and spermidine (Fig. 3) in both cancers and mucosa.

In reviewing the Dukes' classification of the colon cancers, two patients had a Stage A cancer, 13 were Stage B, 18 were Stage C, and seven were Stage D. The mean levels of polyamines and the spermidine:spermine ratio were not significantly different in cancers from patients with early stages of disease (A and B) compared to cancers from patients with more advanced disease (C and D) (Fig. 4).

Seven of the colon cancers were well differentiated, 23 were moderately or poorly differentiated, and four were

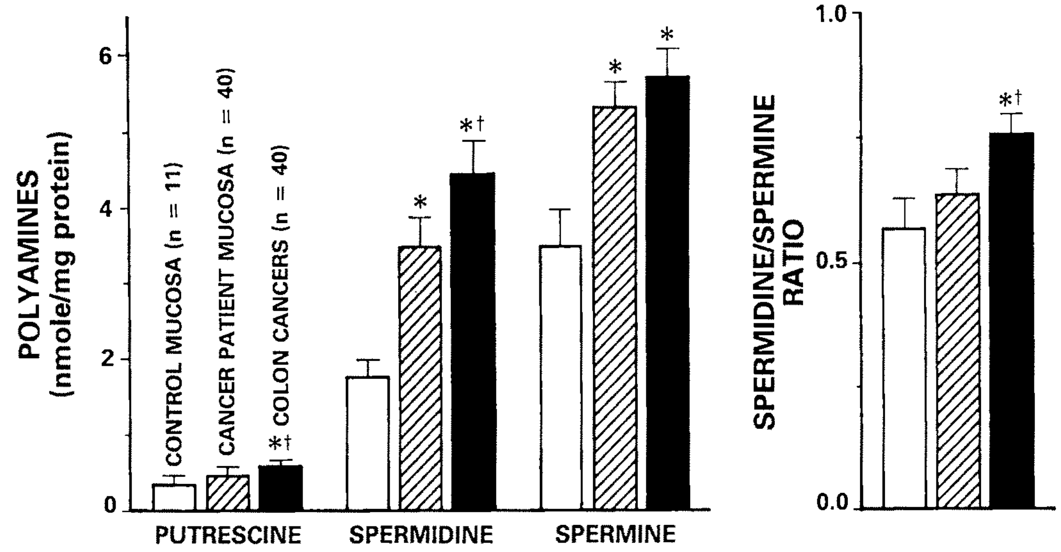

FIG. 1. Polyamine concentrations in control colon mucosa, cancer patient colon mucosa, and colon cancers. $*p < 0.05$ compared to control; $\dagger p < 0.05$ compared to cancer patient colon mucosa.

colloid adenocarcinomas. There were no significant differences in cancer polyamine levels among cancers of different degrees of histologic differentiation (Fig. 5).

GR analysis was done on 30 of the colon cancer specimens. Fifteen (50%) had cancers with no detectable specific high-affinity ($K_d < 1.0$ nmol/L) GR, and 15 cancers tested had specific high-affinity GR levels that ranged from 1.5 to 50 fmol/mg protein. Spermidine levels were significantly increased in GR-positive cancers compared to GR-negative cancers (Table 2). Putrescine and spermine levels were higher in the cancers with high-affinity GR, although the differences were not significant. The spermidine:spermine ratio was significantly higher in cancers with high-affinity GR compared to cancers that had no GR.

Discussion

Elevated levels of polyamines in colon cancers compared to normal colon mucosa from the same patients have been demonstrated. In addition, polyamine levels

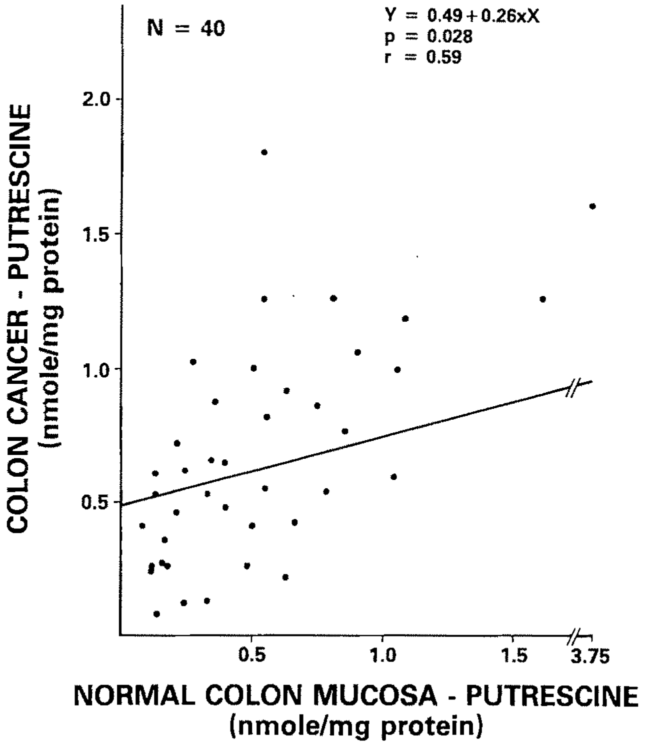

FIG. 2. Linear regression analysis of putrescine concentrations in colon cancers and in normal mucosa from the same patient.

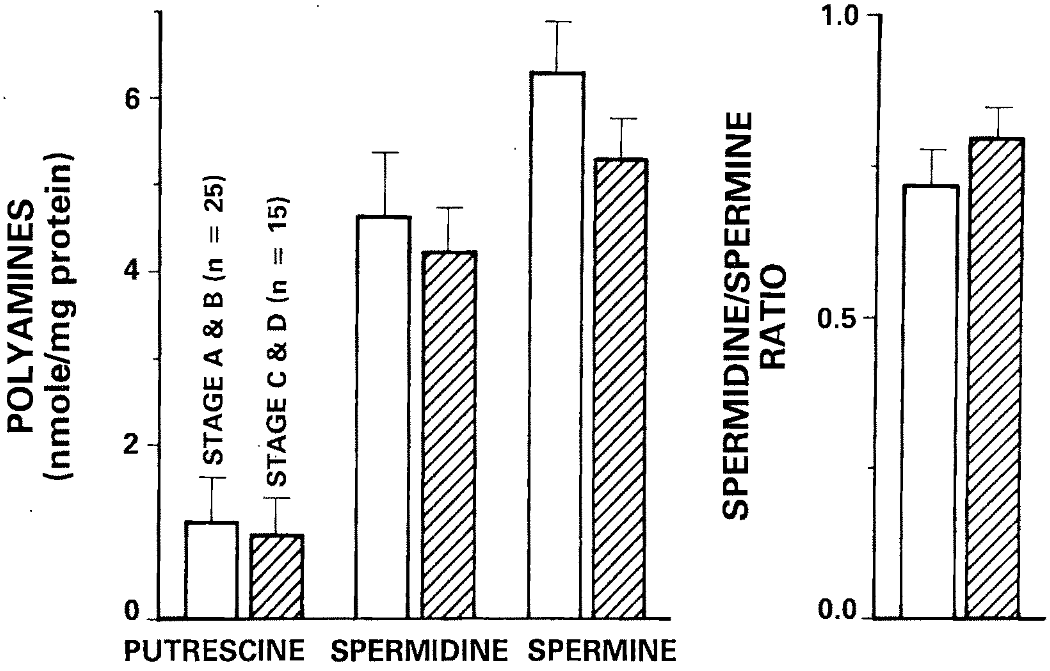

FIG. 4. Tumor polyamine concentrations and stage of colon cancers.

in the normal colon mucosa from cancer patients were significantly higher than levels in normal colon mucosa from patients who underwent colon resection for nonneoplastic disease. These findings suggest a generalized abnormality in the colon mucosa of patients with colon cancer. These findings agree with those of LaMuraglia et al.[20] who reported increased ornithine decarboxylase (ODC) activity and polyamine content in noninvolved colon mucosa from patients with colon cancer compared to colon mucosa from patients without neoplastic disease.

The elevated levels of polyamine in colon cancers in comparison to those of normal colon mucosa have been previously reported.[20-23] Kingsnorth et al.[22] found that spermidine levels were threefold greater and spermine levels fourfold greater in colon cancers compared to the levels in apparently uninvolved resection margins. Porter et al.[23] analyzed ODC and S-adenosylmethionine decarboxylase (AdoMet DC) activity in various types of colonic neoplasms and found a positive correlation with neoplastic progression of colonic mucosal lesions.

No relationship was found between polyamine levels with age, preoperative CEA levels, histologic differentiation, and stage of disease; these findings agree with the studies of Kingsnorth et al.[22] Porter et al.[23] reported increased ODC activity (fivefold to eightfold) in colon cancers compared to normal mucosa, but they found no correlation with the histologic differentiation.

Luk and Baylin[24] found elevated ODC activity in both colonic polyps and in normal-appearing mucosa from 11 of 13 patients with familial polyposis as well as in normal mucosa of first-degree relatives of patients with

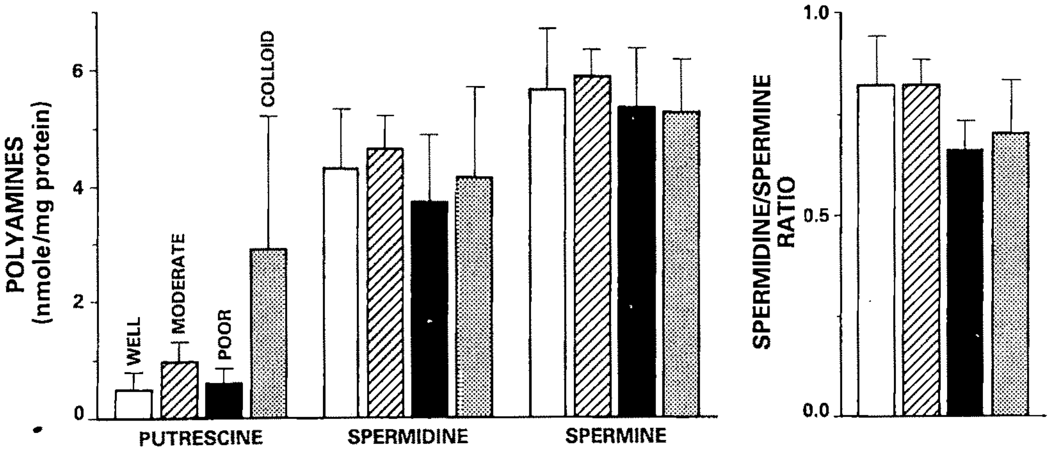

FIG. 5. Tumor polyamine concentrations and histologic differentiation of colon cancers.

familial polyposis. These findings suggest that ODC may be useful in identifying clinically normal family members who carry the polyposis genotype. Increased proliferation of the apparently normal colon mucosa in cancer patients, indicated by increased polyamine biosynthesis, may explain the potential for synchronous and metachronous colon cancers.[25] Increased polyamine levels in apparently normal colon mucosa may be helpful in identifying patients at increased risk of developing colon cancer.

Gastrin stimulates the growth of established colon cancers in mice[4] and enhances colonic and gastric carcinogenesis in rats.[13,26–29] Endogenous hypergastrinemia produced by either antral exclusion or small bowel resection in rats caused increased DNA synthesis in colon tumors or an increased incidence of tumors of the bowel, respectively, in carcinogen-treated rats.[13] Tahara and Haizuka[26] reported that gastrin increased the incidence of carcinogen-induced gastric cancer in rats. Others have found that elevated gastrin levels inhibit the incidence of carcinogen-induced stomach cancers in rats.[27] Singh et al.[28,29] have found that the trophic effects of gastrin on MC-26 mouse colon cancers are mediated by the interaction of gastrin with its receptor.

It has recently been reported that chronic treatment with 3% DFMO inhibits growth of two human colon cancers growing as xenografts in nude mice.[9] The magnitude of tumor growth reduction was greater in the tumor with lower pretreatment polyamine levels. Measurement of polyamine levels in primary colon cancers may have a role in selecting therapeutic agents and in predicting response to treatment.

The significance of these findings is that cell proliferation in normal gastric and colonic mucosa may be controlled, in part, by gastrin and that the growth of colon cancers may also be affected by gastrin. The mechanism of gastrin-stimulated mucosal growth involves polyamine biosynthesis. Polyamines are increased in human colon cancers with GR. The increased levels of spermidine and the increased spermidine:spermine ratio in GR-positive cancers suggest that gastrin may play a role in the cellular proliferation of these cancers compared to GR-negative tumors.

Surgical excision remains the only effective treatment for colorectal cancers. An effective treatment for advanced colon carcinoma has not been developed. Understanding the role of polyamine biosynthesis and its regulation by gastrin in human colon cancers may lead to the development of new treatment strategies that can be used as an adjunct to surgical resection. Antigastrin compounds and inhibitors of polyamine biosynthesis may be promising methods for treatment of selected patients with colonic cancer.

TABLE 2. *Polyamine Levels (nmol/mg protein) in GR-positive and GR-negative Cancers*

	Gr-negative	GR-positive
Putrescine	0.55 ± 0.10	1.65 ± 0.78
Spermidine	3.94 ± 0.70	5.93 ± 0.57*
Spermine	5.18 ± 0.57	6.68 ± 0.63
Spermidine:spermine ratio	0.77 ± 0.08	0.90 ± 0.05*

DISCUSSION

DR. JOSEF E. FISCHER (Cincinnati, Ohio): Dr. Townsend has done his usual elegant presentation of an idea that I personally find very exciting.

This is such a good idea—the concept that the gut, which is the most powerful endocrine producing organ in the body, has some effect on the tumors within it—that I personally am very surprised that, with the exception of a few laboratories scattered around the country, one of which is my own department collaborating with Dr. Townsend on pancreatic cancer, this idea hasn't caught on.

The concept is very attractive, and it raises the question of the possibility that, in tumors that heretofore have not been considered under hormonal control, there may, in fact, be a receptor-positive type of tumor that may lend itself to a whole series of other therapies that were mentioned in the manuscript.

I have a few questions for Dr. Townsend and Dr. Thompson.

First, if I understand the way the study was done, the receptor assays and the polyamine assays were done in adjacent mucosa at the margin of resection.

Have you studied the polyamine content of mucosa remote from the cancer area. If you have, have you found the same changes? I realize that is difficult to do, but the difference would be that if the polyamines were elevated in the mucosa from the cancer and not in the resection margin, this would imply an entirely different mechanism than if it were adjacent to the cancer or at the limit of resection, where you may be dealing with a field defect.

I am not very familiar with where these gastrin receptors are, but my second question is: Where are they on the mucosal cell? Are they on the luminal or the abluminal side? If they are on the luminal side, I think this has one implication. My own guess, knowing nothing about the area, would be that perhaps they would be on the abluminal side and perhaps would be a paracrine receptor for gastrin originating in the submucosal ganglia, although I am not certain. I wonder whether you have that information.

A third question concerns the possible mechanism. Do you envision the gastrin interaction with the colonic mucosa and neoplasms to be a mechanism by which changes in diet perhaps influence the development of colonic cancer, since colonic cancer has been related to both meat and fat intake? Perhaps one could make a connection with an intake of meat as releasing gastrin from the oral end of the gastrointestinal tract, but here, again, I am not certain, and I wonder whether your concept of how this evolves involves an environmental or perhaps a genetic component.

The fourth question is actually one of mechanism. Despite the fact that ornithine decarboxylase is supposed to be the rate limiting enzyme in this cascade of polyamine synthesis, I was intrigued by the manuscript's presentation of what seemed to be different ratios between these three polyamines. For example (not shown on the slides, but in the manuscript), the colloid variety of carcinoma had a very high concentration of putrescine as compared to spermine and spermidine, and although you have made an analysis of the spermidine to spermine ratio, do you have any thoughts about what the relationship between these three polyamines may, in fact, mean?

I enjoyed the manuscript and the presentation very much and I thank you for the privilege of discussing it.

DR. EDWARD M. COPELAND III (Gainesville, Florida): I want to congratulate Courtney Townsend and Jim Thompson on the evolution of their work on hormone receptors, and particularly their work on gastrin receptors in various gastrointestinal tract tumors.

Dr. Townsend has pointed out to us today that polyamine levels are elevated in rapidly growing tissues.

An associate of mine while I was at the M. D. Anderson Hospital, Dr. David Ota, has recently discovered that polyamine concentration in red blood cells is elevated in a rat-tumor model in which malnourished rats are replenished with total parenteral nutrition (TPN). Red blood cells have an affinity for circulating polyamines, and red cell content can be reflective of polyamine synthesis. Dr. Ota interprets his data to indicate that TPN has stimulated tumor growth in his rat model.

My interpretation of this and other rodent studies is that TPN is stimulating growth of noncancerous tissues as well, and therefore an increase in polyamine levels cannot be interpreted solely as an indicator of tumor growth. Thus, I am not certain of what predictive value polyamine levels will be, since both normal and abnormal tissues in replication emit them.

Gastrin, on the other hand, does have a trophic role for many of the normal gastrointestinal tissues. When I was in Houston, our group showed gastrin to be trophic for the small bowel, pancreas, and colon. I am intrigued by Dr. Townsend's discovery of gastrin receptors on colon carcinoma cells and by the possibility that these receptors are responsible for the trophic behavior of gastrin on gastrointestinal tumors.

I am curious to know if colon cancer is more prevalent in patients who have elevated serum gastrin levels. What are the polyamine levels in normal colonic mucosa of patients who have elevated serum gastrin levels? Certainly your group at the University of Texas Medical Branch in Galveston has the patient population to answer such questions for us.

Again, Dr. Townsend, my congratulations on a very fine manuscript.

DR. GEORGE L. IRVIN III (Miami, Florida): I would just like to re-emphasize one of the questions that Dr. Fischer asked.

It is very important to look at the field change in these colon cancer patients. I would just like to ask the authors if there is a field change with your polyamines or with your gastrin receptors close to the tumor which may influence lines of resection and recurrence rates?

My other question is: Have you looked at other benign or premalignant polyps in the colon?

DR. COURTNEY M. TOWNSEND, JR. (Closing discussion): I would like to thank the discussants for their comments.

Dr. Fischer and Dr. Irvin, the polyamines and the gastrin receptors in the mucosa of colon cancer patients were obtained from the margin of the resection. It was usually from the proximal margin, and that was the longest margin. We don't know anything about possible field changes. That is very interesting, and I think very important potentially, and we will certainly begin to take multiple samples at different distances from the tumor.

As far as testing any other part of the colon that is left in place, we have not done that.

The gastrin receptors are membrane receptors.

Whether dietary changes associated with colon cancer work through gastrin mechanism, again I am not sure, although protein is one of the strongest stimulants for gastrin release.

The relationship of putrescine to the other polyamines spermidine and spermine is inconstant. It is the shortest half life of polyamines, and the only ratio that has been found to be constant, at least in normal tissues, in the few cancers that we have studied, has been the spermidine-spermine ratio.

Dr. Copeland, obviously we followed the lead of your group in evaluating the effects of gastrin on tumors arising from the mucosa of the colon. The predictive levels of polyamines in serum and other body fluids that Ota and his colleagues have used may not be so useful in determining the extent of tumor, the rapidity of growth, or even the selection of patients for treatment with polyamine inhibitors, simply because the red cell does act as a sink. However, determination of polyamine levels in the tumors may be very important. We have found in tumors growing in athymic nude mice (four different human colon cancers, two different stomach cancers, and three pancreatic cancers) that sensitivity of the tumors to inhibition by DFMO is inversely related to level of polyamines. We might think that the higher the level of polyamines, the greater the requirement for the tumor growth. As a matter of fact, the more they have, the easier they can avert the adverse effects of inhibition.

The question about serum gastrin levels and development of subsequent cancers is one that we are not able to answer at this time. Travis Solomon and his colleagues in Columbia, Missouri published an abstract a year and a half ago that showed that fasting serum gastrin levels were elevated in about 20% of colon cancer patients. At the present time, we have an ongoing study to evaluate serum gastrin levels, both fasting and food-stimulated, in colon cancer patients.

We have established a human gastrinoma in nude mice that we have had successfully transplanted now for three years. It produces functionally active gastrin in that the stomachs grow large but the colon mucosa, for some reason, does not become hyperplastic in the nude mice. So what the relationship is there, I can't answer.

Is Total Pelvic Exenteration Reasonable Primary Treatment for Rectal Carcinoma?

LESTER F. WILLIAMS, JR., M.D., CHARLES B. HUDDLESTON, M.D., JOHN L. SAWYERS, M.D., JOHN R. POTTS III, M.D., KENNETH W. SHARP, M.D., and SCOTT W. McDOUGAL, M.D.

Total pelvic exeneration (TPE) is reasonable primary surgical therapy in select patients with large bulky locally invasive rectal cancers that can be removed *en bloc.* Many do not have either nodal or distant metastasis. Furthermore, TPE can be curative and often is palliative for similar lesions that are recurrent or nonresponsive to radiation therapy. Operative mortality rates should be under 10% and can be under 5% for primary cases. Although improvement in preoperative management and operative technique, especially with urinary conduits and postoperative care is clear, both early and late complications are significant. Unfortunately, preoperative identification of those patients requiring TPE rather than abdominoperineal or low anterior resection remains poor. Furthermore, recent improvements in techniques for pelvic slings to prevent small bowel entrapment and protection from irradiation or myocutaneous flaps to obliterate the massive dead space are not yet clearly established as preventors of either early or later complications.

IN 1975 ONE OF THE AUTHORS published an experience with pelvic exenteration as a palliative procedure.[1,2] This material, which included five patients with total pelvic exenteration (TPE) for rectal carcinoma, stressed these patient's debilitated, unmanageable state, which was associated with such bulky tumors. A recent 2-year experience with five more patients needing TPE for rectal cancer uncovered some reluctance to apply the principles of ultraradical surgery to rectal carcinoma especially as primary therapy even with less sick patients. This dichotomy lead to a review of the Vanderbilt experience with TPE for rectal cancer. These data plus an assessment of the factors necessary to determine if TPE is reasonable surgical therapy for rectal carcinoma are the basis for this report.

From the Department of Surgery, VA Medical Center, and Vanderbilt University, Nashville, Tennessee

Materials and Methods

Ten new patients were added to the initial five[1]; all had TPE for rectal cancer. In this review, as well as the literature review, it is possible that some patients whose lesion might have been classified as rectosigmoid by some (higher than 15 cm from the anal verge) are included because they were listed as rectal carcinoma. However, no patient whose lesion was sigmoidal or colonic is included. Thirteen of the 15 patients were males, the average age was 57.6 years, and there were no operative deaths. The information is best analyzed as two groups; the ten patients with one operation (their TPE) and five patients with one or more operations before their TPE (Table 1). In the first group (Group A) one patient had TPE for palliation because peritoneal implants were present and the other nine had curative resections. There were two patients with early complications (two wound infections and one conduit fistula) and four patients with late complications (two colostomy difficulties and two small bowel obstructions). Four patients are alive with no evidence of recurrence (NED) 15 years, 7 years, 34 months, and 16 months post-TPE. The palliative patient when last evaluated at 15 months was alive but had further evidence of visceral recurrence. In contrast, the five patients of Group B with at least one operation before their TPE, all had early postoperative complications (three wound infection, two abdominal abscess, three conduit leak, and two organ failure) and three also had late complications (one colostomy difficulty and two perineal problems). Two patients are alive without evidence of recurrence at 24 and 36 months. In Group B two patients were operated upon for recurrence: one 32 months after low anterior resection with negative nodal disease with postoperative

radiation therapy and one 9 months after resection for perforated cancer with postoperative irradiation. There were four patients who had early reoperation: one after colostomy to relieve acute obstruction, two after recent explorations during which attempts at *en bloc* resection failed (one of these is also in the recurrent group so the TPE was the third operation), and one because the possibility for a more extensive but curative operation was considered moot.

Assessment of their pathologic stage was especially instructive. The initial belief was that all patients had secure histologic evidence of organ invasion. Because of the well-known variation in the manner by which invasion of an adjacent organ with rectal carcinoma is staged, especially when lymph nodes are negative,[3,4] the details of the pathologic reports were reviewed. Detailed review of the 14 available protocols (the patient who is 15 years postoperative had only conclusions available) showed that in three patients there was histologic evidence of invasion close to the adjacent organ but not into this organ, namely, tumor not inflammatory reaction in the capsule or in adhesions to the organ. In each of these three cases histologic invasion well beyond the immediate perirectal material was present. Figure 1 summarizes these data. Only one patient had known residual cancer postoperatively, and this patient was one of two with positive nodes from the 11 patients with positive organ involvement. In contrast, two of three patients from the close group had positive nodes. Yet all three of the close group are alive without evidence of recurrence whereas only four of the 11 are similar and all these are from the negative node group.

Two patients, both from group B, had had prior radiation therapy (RT). One female had been treated 3 years prior to the present surgical therapy for perforated carcinoma with resection and full postoperative irradiation. After cystoscopy revealed tumor invasion, an attempt at *en bloc* resection was abandoned and the patient transferred to Vanderbilt. TPE, which was accomplished at early reoperation, removed all gross disease, but the postoperative course was stormy. Recurrence was obvious by 6 months and death occurred at 8 months. The second patient recurred 9 months post-RT after resection for perforated cancer. Another Group B patient began a course of irradiation before he consented to the TPE 2 weeks after his initial procedure. He completed his RT postoperatively even though he had negative nodes and was one of three patients with close organ involvement. He is alive NED 24 months post-TPE. Two additional patients received early postoperative RT. Both were from Group A, one with positive nodes and close organ involvement and the other with negative nodes but positive organ involvement. Both are alive NED 16 and 34 months post-TPE. Yet another patient from Group A with negative nodes but positive organ invasion refused early RT only to recur at 12 months and died at 30 months when delayed RT was not effective. Of nine patients including the one with peritoneal implants who did not receive early postoperative RT, three are alive with NED (15, 7, and 3 years), three are alive with recurrence (15, 16, and 18 months) and three have died all with recurrence (11 months, 18 months, and 9.25 years).

TABLE 1. *TPE for Rectal Carcinoma*

5 Multioperations
  2 for recurrence, 3 for poor staging; all had postoperative complications
  2 are alive NED (24M, 36M)
10 Single operations
  1 for palliation (peritoneal implants)
  2 had early postoperative complications
  4 are alive NED (15Y, 7Y, 34M, 16M)

Data pertain to 15 patients (13 males, two females) (average age: 57.6 years) with no operative mortality rate.

In summary, these 15 patients with extensive local rectal carcinoma had a TPE without an operative mortality rate but with a 30% early complication rate and a 50% late complication experience. Nevertheless, all but one (the female with early recurrence and death) enjoyed at least 10 months of good palliation with an average survival of 38 months. Six including two with positive nodes remain alive with NED (15 years, 7 years, 3 years, 34 months, 24 months, and 16 months).

Results

This attempt to analyze all patients undergoing TPE for rectal carcinoma recorded in English journals uncovered many problems.[1,2,5-34] As mentioned earlier, some patients with rectosigmoid cancer are undoubtedly included in summaries especially in reviews of lower colon, colorectal, or rectosigmoid cancer.[11,13,14,21,28] Occasionally, anterior or posterior exenteration is mixed with TPE. Clearly there is overlap of case material especially where centers updated earlier experience or emphasized different approaches.[1,2,7-11,16-19,29-31,34] Further-

more, there are reports that must contain acceptable cases,[25–28] but details are not clear enough for their cases to be included in this summary even when others have used their data.[11] Finally, because some include TPE even while extending the procedure further as with sacral resection,[17,20] others may have acceptable patients within their more radical surgical treatment groups.[32,33] Review has been further complicated by grouping colon with rectum or PE with TPE when data on staging, nodal or organ involvement, operative mortality rate, complication rate, or even survival data is provided. Taking into account all of these conditions, Table 2 lists 217 cases of TPE for rectal carcinoma. Although these data may contain a few overlapping patients,[10,11] it is more likely that some with TPE are missing (as many as 22 patients).[11,25,27] As noted later, such inconsistency in case material may not be critical because only trends can be established because of other variability.

While 53 of these 217 cannot be labeled accurately,[7,8,13,21,22] 54 were done for recurrent cancer.[11,17,18,20,22,24,33] These latter include 25 patients who had removal of bone as well as TPE.[7,11,17,10,33] This leaves 110 patients treated for locally advanced rectal carcinoma with a TPE as the primary surgical procedure.[5,6,7,10–12,14–16]

While early series with large numbers of pelvic exenterations reported operative mortality rate near 15%,[7,9–11] more recent reviews with emphasis upon exenerations for colorectal cancer note series with operative mortalities closer to 10%.[10–13,16] Indeed, most believe current care standards for TPE as the primary operation for rectal cancer that has not been irradiated should produce operative mortality rate below 5%.[1,10,20,25] Early reports of a 45% complication rate[8,9] are paralleled in more recent series[14,15] with the best improvement occurring in relation to urinary conduits and the management of their complications.[2,28,31,35] However, in spite of these formidable surgical problems, all note impressive 5-year survivals that are always over 20%[8,9,12,14] and usually over 35%.[10–13,16] Thus, we are a long way from a procedure which is "only for conjecture, hope and further study."[5]

Discussion

Data from the reported cases of TPE, with or without extension to even more radical procedures such as sacral resection, clearly document both cures and palliation of recurrent rectal carcinoma.[7,11,17,18,20,22,24,32,33] However, most note the very limited potential for any given patient at the point of recurrence especially when there is also irradiation treatment failure. In the largest series[32,33] operation for cure was feasible, even when extensive, in only 24 (39%) of 61 referred highly selected patients. Thus, an apprehensive attitude with lesser surgery as primary treatment reserving the ultraradical procedures for recurrence could be justified only if primary radical (TPE) is not effective. Primary TPE for rectal carcinoma in properly selective patients is very effective treatment.

Few would deny that the immediate outcome for colorectal resection has improved in the past few decades or that resection of rectal carcinoma offers the only possibility of cure. Yet improved survival is not clear.[18,36,37] Furthermore, local recurrence is the most common type of failure.[18,32,38] Local recurrence has been recorded in over 50% of cases in many series. Indeed, in reviews involving 1329 patients reported in the 1980s an average of local only (not as part of diffuse disease) recurrence of 15.4% (9–24% range) was found.[18] Because local recurrence can be equated to lower rectum and tumor through the wall, it is not surprising that local recurrence of 30–35% with through the wall but negative nodes is worse than that (20–25%) with tumor within the wall but positive (few or close) nodes. Finally, although all agree positive nodes are usually a determinant for local recurrence, they are not the sole factor.[41,42] With low anterior resection, local recurrence was similar for those with negative nodes[41,47] and those with positive nodes.[45–51] Furthermore, size is not a determinant of recurrence (unless gross tumor is left as residual) or survival.[13] The prognostic implications of rectal wall penetration by tumor, nodal spread, or direct invasion of other tissues and organs that are at the heart of many current discussions about staging systems[3,4,38–41] highlight the dilemma about surgical techniques. When results for lesions penetrating bowel wall but not involving metastatic nodes are no better than those seen with mucosal lesions that have positive nodes, as is the case for rectal cancer,[37-43] concern about more extensive local therapy follows naturally.[15,40-45] When this concern is compounded by considering even more local spread, invasion to adhesions or adjacent organs, as is appropriate for discussion of TPE as primary therapy, the data become less clear because some stage this as distant metastatic disease (Dukes' D[38] or even D_1[34]) while others consider it as local disease (B_3).[39,42] Comparison of cases with invasion to adjacent organs is difficult if not impossible with such variation in the standard staging systems.[3,4]

Carcinomatous extension to adjacent tissues or organs is an important concern because it occurs in 5–10% of colorectal cases.[13-15,21,36,38] The need to remove an organ that is grossly and microscopically invaded if one is to cure cancer is easily grasped and often acted upon. However, more subtle findings cause confusion. Adjacent organ involvement is an independent variable for survival,[4,36,39,44] and pathologically proven tumor penetration has a significantly poorer prognosis than clinical but not pathologic invasions.[21] The latter is termed close. Perhaps most importantly, only 40% of the adhesions at the interface of tumor and adjacent structure are caused by inflammatory response[21,36] or even by an abscess[16] so the remaining majority (77%[14], 66%[15,21]) are tumor bearing. Perhaps these variables explain the wide divergence of TPE from 1.6%[11] to 4.7%.[14] They certainly should contribute to the often noted feature of rectal cancer, local recurrence without evidence for systemic disease.[36-38,41,42] The role of venous, neural, or lymphatic infiltration in the absence of organ, adhesions, or nodal disease is unclear but probably also contributes to unexpected local recurrence.

Not only must the surgeon be aware that apparent extension of tumor can be either tumor, which if entered will almost certainly lead to recurrence, or inflammation, but the surgeon must also realize that many bulky tumors with established organ invasion will not have nodal metastatsis. For the reported cases of primary TPE where specific information has been provided, 60% had negative nodes.[11-15,20] There is less secure information about organ invasion, but what little is available suggests a 60% pathologically proven infiltration. These data show that there is a population of patients with rectal carcinoma who will have extension of tumor beyond the rectal wall into adjacent organs. In many there will not be nodal spread. Although the adhesions may be dense,[15] they can appear inflammatory but still contain tumors.[21,36] As noted by Brunschwig some time ago, with rectal cancer the majority of patients will be males 77%.[8-12,14,16,17,20,33] Although there may be some evidence for effective chemotherapy and/or radiation therapy,[22] most believe these patients have only one chance for cure, total removal of tumor, TPE.

The authors' experience, as well as that recorded in the literature, shows that some patients require a second operation because neither the patient nor the surgeon are prepared for TPE. Such patients have a higher complication rate and may have both a high local recurrence rate and a poor prognosis. Unfortunately, the individual cases cannot be analyzed for these latter two details, although most series contain such patients who appear to have a poorer long-term outcome. In earlier series, preoperative assessment emphasized metabolic, nutritional, and infection control for patients with obvious locally advanced or recurrent disease.[7-11] Indeed, improved outcome and, therefore, the opportunity for meaningful palliation was attributed to just such a program.[1,2] The more recent cases still included two patients with recurrence and one patient with late stage disease, but the others were not debilitated and unmanageable. It is not clear if similar experience is occurring elsewhere. When the patient is less obviously harboring a bulky locally advanced lesion, the opportunity for both patient and surgeon to be unprepared for TPE increases. The hope that newer preoperative tests including computed tomography (CT) or ultrasound (US) would permit better staging has not materialized. Although some stress the importance of these tests,[17,29,30-33,46-49] others believe CT may be no more reliable than digital examination.[47] Data for endosonography[50] in locally advanced rectal lesions is not available, but invasion beyond muscularis propria or into lymph nodes can be detected. Other special tests such as cystoscopy[48] or even lymphoscintigraphy[49] are not obtained as routine evaluation.

Thus, the properly selected patient in this thesis is one whose rectal carcinoma at the time of initial evaluation has direct invasion into adjacent organs such as bladder, prostrate, or seminal vesicle but whose nodal metastasis is minimal and localized in the pelvis if present at all. While some patients may have such advanced local disease because of neglect,[1,14] concern should occur with all bulky or fixed tumors. Most will be males with these findings assessed by routine physical examination.[36,45,46] Unfortunately, CT and US may not improve either sensitivity or specificity. The surgeon needs good clinical suspicion if preoperative plans, which are essential as well as extensive for both the patient and for special operative techniques, are to be correct. Because intraoperative decisions can be difficult and insecure, the indecision about the need for TPE gets compounded.

The conduct of the TPE operation follows the principles championed by Brunschwig and Daniel[7] with the refinements, especially for urinary diversion, established by others.[8-10] When cure is possible, the wide margins not only extend laterally[11-20,25-28,36,37] but also encompasses the mesorectum,[53] local nodes[40] including unrecognized small (0.5-m) ones,[54] and pelvic adhesions.[14-16,21,36,37,41,42,44,45,51,52,57] Furthermore, when such extensive procedures are planned, there is less chance for compromise on distal margins.[51,55,56] Wide perineal resection is possible for very low lesions just as establishment of bowel continuity is for the higher lesion.[10,14] Rarely is resection of bone[7] including sacrum appropriate.[11,17,20,33] The goal is the removal of all central tumor mass regardless of its size because neither cure nor good palliation occurs if residual tumor exists.[1,11,14,16,20] Reconstruction usually involves an ileal loop,[8-18,25-28,35] but it may use a jejunal loop,[2] sigmoid conduit diversion, or even the newer continent urinary diversion procedures.[35] When these procedures are being done for recurrent tumor or for radiation failures, disappointing experiences,[10] most believe that extensive lateral wall dissection is not warranted both because it increases the complication rate and because when positive nodes are found neither cure not palliation follows.[1] However, newer techniques especially those with myocutaneous flaps may change this attitude.[19,20,31-33]

Concern about control of the massive dead space left within the pelvis after TPE initially centered on prevention of early infection and late small bowel obstruction.[8-11] Thus, efforts were made to fill the defect with omentum[58] or to prevent small bowel entrapment with perioneal and/or omental slings. More recent emphasis has been on mesh slings,[59-61] especially absorbably ones that could keep the small bowel out of the pelvis during early postoperative RT. After experimental success,[59,60] Devereux et al., who has used polyglycolic acid mesh in 60 patients, noted the need to place the mesh at the level of the umbilicus, thus depending upon absorption later to decompress the abdominal contents. Devereux et al.[59,60] reoperated upon six patients (as in two patients in this study) months after the sling was placed finding no residual mesh as well as no evidence for infection. Neither the uses of balloons, breast prosthesis, or the like within the pelvic space nor the use of an absorbable mesh address the issue of late small bowel obstruction. Use of myocutaneous flaps to close defects especially after irradiation failure has suggested yet another way to deal with both perineal closure and obliteration of pelvic death space.[19,20,25,32,33,63-65] The possibilities include rectus, gluteal, or thigh myocutaneous procedures as well as bilateral tensor fascia lata grafts. Clearly these should be utilized during the primary operation.[19] Thus, they need to be planned for preoperatively. Their use has controlled sepsis, fistula, and perineal problems, but data to show improvement in small bowel obstruction are not yet available.

Preoperative radiation therapy impacts upon these patients in two ways[67-70]: (1) when given immediately preoperatively it may increase the operative complications[35] but it is also possible that it can downstage the tumor to make it operable[69] and (2) to make a lesser operation feasible.[22,70] While almost every review notes or comments upon an increased complication rate in previously irradiated patients or justifies newer procedures such as myocutaneous flaps to improve results, detailed analysis is not feasible given the way data are presented. The arguments about the value of postoperative radiation for patients with TPE for rectal cancer parallel those currently occurring for colorectal carcinoma with low anterior resection or abdominoperineal resection. Because analyzable data are not available, this is not discussed further.

The second part of this thesis requires the TPE to be effective therapy, that is, it must be able to be done safely and produce good results. As noted when all reported cases were summarized, the operation can be accomplished with under 10% mortality rate,[10-13,16,18] but with significant complications. If one emphasizes primary TPE as the first operation being well planned for newer surgical techniques in fit patients who have not had prior pelvic radiation, both of these figures improve significantly. The cures, which are regularly over 20%[8,9,12,14] and often over 35% at 5 years,[10-13,16] are more than would be anticipated with more local resection and postoperative RT for the residual disease. This latter is the only available alternate to TPE for all of these patients with the possible exception of the few with both negative nodes and only close organ invasion. This small group is almost impossible to define with methods used today. Most grant that even when cure does not occur this procedure offers significant palliation.[1,11,14,16-18,20,23] When recurrence occurred, it was often 10 or more months post-TPE (10 months[14], 20 months[11], always after 10 months in this series) becoming manifest 4–8 months before death. Many have noted the absence of symptomatic pelvic recurrence[1,14,16] even with visceral spread or carcinomatosis. This later feature is very different from the course of recurrence in lesser operations.[38,52]

Based upon this experience and the review of data available, TPE as primary therapy for rectal carcinoma should be applied in selected patients. It offers both the only chance for cure and a reasonable potential for palliation when no gross tumor is left. Newer techniques and improved management both before and after operation have made the procedure safer, but future improvement in dead space management is necessary. Unfortunately, preoperative staging remains poor especially for selecting these patients from others who need a lesser procedure. Only an alert surgeon willing to consider TPE as primary therapy can fill this critical gap.

DISCUSSION

DR. WILLIAM D. JOHNSTON: I appreciate Dr. Williams's giving me a copy of his manuscript to review.

You have heard a very erudite presentation of a very difficult problem, and when you have a chance to read the manuscript, you will also be convinced that they have really milked all of the data to try to come up with solid information on which to base several difficult decisions. Those difficult decisions, as I see them, can be summarized as falling into four categories. First, the difficulty of preoperative assessment; second, the difficulty of intraoperative assessment toward making the decision of what operation to do; third, whether or not you are going to use postoperative radiation therapy; and fourth, what to do about the pelvic dead space.

I am going to comment on my present approach to each of these four problems, and I welcome your response of what you, Dr. Williams, and those who choose to discuss this paper do. I believe, as you have shown with your data, that the pelvic (vaginal and rectal) exam is the most important preoperative test towards assessing the local extension of tumor. CT scans and MRI are helpful when they show evidence for positive distant metastasis. However, in the absence of distant metastasis, it is important to determine preoperatively the local extent of cancer in the pelvis, and we believe that we can do this best when the patient is under anesthesia during the pelvic exam. We usually do this using general anesthesia at a date prior to the date of the planned resection. However, if you are going to do the exam at the same time of your definitive operation, I think you should have the patient and his family, prepared for the possibility that you are going to do a total pelvic exenteration. This would mean having the patient educated by yourself and the stomal therapist, and having the location of both stomas marked on the skin in the proper position.

Secondly, what do you do after you have begun operating on a patient whose pelvic exam indicated the likelihood of needing to do a total pelvic exenteration. The pelvic dissection doesn't start until you are reasonably certain that there is no metastasis outside of the pelvis. After you are certain of that, the pelvic dissection should start along both common iliac vessels and extend down the external iliac vessels, and then extend posteriorly into the obturator fossa, down to the internal iliac vessels with medial mobilization of the ureters and while mobilizing the bladder away from the pubic bone. By not transecting the ureters or any of the blood supply up until this point, all of this can be done prior to making any commitment to proceed with the pelvic exenteration. At this point, you can squeeze from both sides to try to assess the presence of tumor between the anterior wall of the rectum and the prostate and/or the posterior trigone of the bladder in a male, or between tumor extension into the cervix, vagina, or uterus in a female, without extension into the urinary bladder to allow a posterior exenteration, without resection of the urinary bladder in addition. Even with all this dissection in preparation of making a commitment, the decision is still difficult to make; but you are giving yourself the best opportunity to make the right decision by doing this much dissection before committing yourself by transecting the ureters and the blood supply to the pelvic viscera. If a fibrotic extension is proceeding laterally from the area of the anterior rectal wall and prostate or trigone of the bladder, then I believe that you should proceed with a pelvic exenteration, rather than hope that the fibrotic reaction is not due to cancer. If this amount of dissection should prove that there is a good plane between the anterior rectal wall and the prostate or bladder, then I would proceed with making an incision through the peritoneum at that point and dissect down between the bladder and the rectum until I reach a fibrotic reaction. If I were to reach a dense fibrotic reaction including the trigone of the bladder or the prostate gland, then I believe that this would indicate a total pelvic exenteration. Dr. Williams's assessment of the data confirms that it is very difficult to tell whether or not there is cancer in this location, but I think it is better to resect adequately than to find out postoperatively that tumor has been transected in the process of trying to do an abdominal perineal resection, when a total pelvic exenteration should have been done.

Thirdly, what do you do about radiation therapy. If our preoperative assessment reveals a primary operable case to be curable by total pelvic exenteration, we tend not to use preoperative radiation therapy, but to wait until all the histology is completed on the operative specimen and to use postoperative radiation therapy after total pelvic exenteration if there are multiple lymph nodes positive, or if there are lymphatic extensions or perineural or perivascular microscopic extensions beyond the primary tumor.

Fourthly, what do we do about the pelvic dead space. Just as Dr. Williams has pointed out, it is very important to fill the dead space with something other than small bowel to help prevent entrapment and obstruction and other complications regarding the small bowel. I most frequently fill it with omentum when it is adequate. However, quite often it is not adequate, and I call on the help of a plastic surgeon to consider a myocutaneous flap first; I think one of the most helpful flaps in this situation is the rectus abdominis myocutaneous flap based on the inferior epigastric vessels. The surgeon doing the resection will have to be careful not to transect the inferior epigastric vessels, which can be done without compromising the pelvic dissection.

Leaving the pelvic cavity filled with something other than small bowel aids greatly in reducing the complications that can result from postoperative radiation therapy. It is also important that the radiotherapist use multiple fields and multiple positions of the patient to try to avoid excessive dosage to any area of small bowel.

I appreciate your asking me to discuss this paper and providing me with the manuscript ahead of time. I commend you on an excellent and thorough coverage of the difficulties concerning the question of total pelvic exenteration for rectal cancer.

DR. MAURICE J. JURKIEWICZ (Atlanta, Georgia): First of all, may I compliment Dr. Williams on a very nice presentation and a superb paper. I want to thank him for providing me with an advance copy. Not only did I learn a great deal from it, but it also gave me a little feeling of a déjà vu. When I was a resident, I participated in these 43 cases done by Dr. Bricker and his colleagues, Harvey Butcher and Allen McAffee. I remember all of the things that we went through in an effort to prevent the immediate complication of small bowel obstruction.

I rise to comment on what has been termed the pelvic dead space. May I call your attention to a principle articulated by Allen Kanavel in the 1920's and published in SG & O. Kanavel called attention to the principles involved in the treatment of wounds with noncallapsing walls. Examples include empyema and chronic osteomyelitis, as well as the pelvic dead space referred to by Dr. Williams. Kanavel pointed out that for healing to occur, the wound surfaces have to be in contact. If such contact is prevented by bony walls as in empyema, chronic osteomyelitis of the femur or tibia, or the case of the bony pelvis, then another strategy is indicated.

Kanavel advocated the use of muscle flaps to accomplish the desired contact of tissues so that healing could occur.

Radiation treatment of patients with rectal cancer adds another dimension to the problem of pelvic dead space. I would submit that the sling, although attractive in concept, would do little for the problems attendant upon preoperative irradiation.

Our experience is with the chronic wound and not the acute.

(Slide) We have treated 24 patients, 16 of which had a persistent perineal sinus following proctocolectomy for Crohn's disease. In those patients, we initially used gracilis to fill the pelvic dead space. We had failure in three, a figure consistent with the scanty literature on the problem.

Gracilis is a difficult muscle to use. It is a long muscle, and it doesn't provide quite enough tissue for what you want it to do. Therefore we turned the gluteus. In those patients, (13 in all;) we had no failures with the pelvic wound. We treated the three patients in whom the gracilis failed by a secondary procedure with the gluteus. All three patients are now healed.

More importantly, and pertinent to this discussion, however, are those patients who had radiation for rectal carcinoma follwed by radical abdomino perineal resection. In eight such patients treated with gluteus there were no failures whatsoever. We had to supplement the gluteus in three with gracilis or rectus abdominis to adequately fill the pelvic dead space.

There is no question in my mind that one can create a living pelvic diaphragm and fill the dead space at the same time. A combination of muscles may be necessary. I would agree with Dr. Johnston that the rectus abdominis muscle provides the best possibility for the reconstruction of a living pelvic diaphragm.

Leonard Miller, formerly one of our residents, is working with Glenn Steele at the New England Deaconess Hospital. He has been using a flap of entire posterior skin of the thigh, de-epitheliazed to fill the pelvic dead space and to recreate the pelvic diaphragm. This flap is based on a branch of the inferior gluteal artery.

In my opinion, muscle flaps have made a real contribution to the decreased morbidity in patients similar to those described by Dr. Williams.

DR. CLIFFORD WHEELESS (Baltimore, Maryland): I would like to thank my host, Dr. James Arnold of Baltimore, and the Southern Surgical Association for the privilege of attending this meeting and the opportunity to discuss this excellent paper by Dr. Williams and his colleagues from Nashville. The paper was thoroughly prepared. The authors are to be commended on the clarity of their presentation.

We might now consider that Phase I in total pelvic exenteration for selected cases has been accomplished, as has been so ably reported to you today.

We believe that we have now entered Phase II of total pelvic exenteration, namely, the emphasis on improvement of quality of life for these unfortunate patients.

There are three quality of life procedures that are now under current development. Dr. Williams has mentioned two of them.

(Slide) The first quality of life procedure is an alternative to urinary diversion by the Ileal Loop (Bricker Bladder) by performing a continent urostomy, such as the nonrefluxing Koch's pouch.

(Slide) The second quality of life procedure is an alternative to End Sigmoid colostomy, when adequate cancer surgery allows a sphincter-saving procedure by performing a low coloproctostomy ultilizing a low pressure reservoir of detubularized colon, such as the rectal "J" pouch with a Strassburg-Baker anastomosis.

The above two techniques offer the possibility of elimination of ostomy bags from the abdomen.

(Slide) A third quality of life procedure in females is the construction of a Neo Vagina by using the risidua of the Omental "J" flap. The blood supply for the flap is based on the left epigastro epiploic artery. Traditionally, the flap has been used to close off the pelvic inlet. We have found the flap useful in constructing a cylinder that can be sutured to the vaginal introitus and lined with a split thickness skin graft.

My question to the authors: Is there any consideration for these procedures in this series of patients?

DR. BENTON M. HILBUN (Tupelo, Mississippi): During my training period under Dr. Hardy, we were taught that rectal carcinomas should be treated with radical surgery and that the only chance for cure was total surgical excision.

This continued in my practice for the first ten years or so, and although the number of cases of this nature that have come to my care have been limited, in this manner we have continued to do a total surgical excision, often in conjunction with the urologist, and in some cases, a gynecologist.

However, in the last year or two, influenced perhaps, by the chemotherapist and the radiation oncologist, I have felt somewhat guilty about proceeding with such a radical procedure, and we have been influenced to use preoperative radiation and chemotherapy, rather than initial surgical excision.

I want to thank Dr. Williams for reinforcing the concept of initial excision. It gives me some confidence to go ahead with this radical surgery, when I have, in the last year or two, felt somewhat guilty about it.

I have one question for Dr. Williams. If, at the time of laparotomy, unsuspected liver metastases were found, would he still continue with the total pelvic exenteration, and would he consider intra-arterial hepatic fusion of 5-FUDR postoperatively?

DR. ROBERT E. CONDON (Milwaukee, Wisconsin): It seems to me that the crux of this problem is the large bulky, truly low-lying rectal carcinoma, a sort of carcinoma that no single surgeon sees in any great number over any reasonable period of time; so the first caveat I must give you is that my remarks are based on a relatively limited personal experience.

Second, it seems to me that within the total spectrum of patients who have such tumors, defining the need for pelvic exenteration is relatively straightforward, given the assistance of CT examination and the use of knowledgeable digital and manual examination in those patients. But there is one subset within the spectrum of patients where I don't believe those modalities are always sufficient; at least in my experience they are not. That is the male with a bulky anterior rectal tumor where the issue is: Has it invaded the prostate, the seminal vesicles, or the base of the bladder? If it hasn't, obviously the tumor can be excised without incurring the disability that is associated with pelvic exenteration.

On the other hand, it is a major disaster for the patient to blunder into a tumor while dissecting the plane below the bladder and anterior to the rectum, since that sets the stage for pelvic and perineal recurrence, which is not easy for any of us to manage successfully.

In approaching this problem, therefore, I have for some years used radiation therapy, directed not so much at improving the long-term prognosis, but at reducing the bulk of the tumor and making a definitive judgment about the need for pelvic exenteration somewhat easier to make.

To the consternation of my radiation colleagues, I operate on these patients as soon as they have completed a full course, usually of 6,000 rads or so of irradiation, and have not waited the traditional 6 to 8 weeks afterwards, because at that early stage you don't run into some of the secondary radiation effects that increase the difficulty of pelvic dissection.

More recently, I have been impressed by my urology colleagues with the real utility of using transanal ultrasound examination. It grows out of their use of this modality to examine the prostate, but has been helpful in adding to the body of knowledge that allows you to make a judgment about whether, in fact, that crucial plane anterior to the rectum is involved with tumor or not.

Les, it seemed to me that you indicated you were always able to arrive at these judgments with confidence using only your finger. My finger is not so sensitive. I wonder if you can give me some advice about how to increase its sensitivity.

DR. HIRAM C. POLK, JR. (Louisville, Kentucky): I rise to make three different emphases from our essayists.

I think that, first of all, you have done us a good service by bringing this to our attention. It is obvious that there are literally hundreds of patients who have been rendered well from this operation, and who have not been reported in a long time basically because it is an operation that has been a standard procedure now for more than 20 years.

I think what happens is that we do lose sight of the operation's utility, and periodically it is very valuable for all of us to be reminded of its utility. Certainly it accomplishes exactly what you have described: low mortality and morbidity, always under 10%, nearly a 40% cure of the cancer forever in every patient.

Two emphases that are different than yours:

We see many more women requiring this operation than you have indicated. Women have often had hysterectomy earlier in their life, and then develop a rectosigmoidal tumor which develops bladder invasion. She is quite a suitable candidate. I think Dr. Wheeless obviously reflects that in his comments, in the sense that they are amendable to re-resection, and indeed, a little bit easier.

The third point, about how to pick these patients out has been written down a number of times, I think, and is a paradox but a useful hint. That is the work that Spratt[1] describes so clearly in talking about the large bulky nonmetastasizing variant of colon cancer. If you have a large tumor that is free of liver metastases, you begin to think that is an ideal case to work on, because not only is it going to be free of liver metastases, but, more often than not, it is going to be free of nodal metastases. Paradoxically, it is the big tumor that is more amenable to this kind of treatment. It needs the treatment more, but don't let the size of the thing make you back off, because truthfully, I think those are the patients who are ultimately the most likely to be helped by this.

You have done us a service by emphasizing this, and I appreciate the paper.

DR. L. F. WILLIAMS (Closing discussion): Let me thank all the discussants and attempt (for the sake of time) to cover the highlights in reverse order.

As always, Dr. Polk has pointed out important observations from the past. In fact, the very patient who has the big bulky tumor and does not have metastatic disease is the person we are talking about. The reason I emphasized the digital examination was only because the current literature, Dr. Condon, is so heavily weighted toward everything else. In fact, it is still possible to make this "guess" by digital exam, and you yourself know that I am certain. It may be true that the intrarectal ultrasound is more sensitive than we have known.

I don't know why there weren't more females reported, Hiram, but I suspect it was from my emphasis on this as a primary treatment rather than as therapy for recurrent disease. We may have excluded some women who might well have had TPE, but I did not run across the observation that you offered.

What to do in the presence of liver metastases? We defined this as pallative, that is no longer a patient available for cure, but as we reported in 1976, in selected patients with big, bulky tumors, foul smelling fistula and the like, TPE provided reasonable palliation. Thus, I might well do a TPE if I found liver metastases in such a patient.

The rest of the discussions actually related to experiences from the series that I reviewed. For the sake of time, I would point out that the new techniques include myocutaneous flaps for reconstructions, and ways to prevent ostomies.

Is it still true, however, that many patients may be treated by surgeons who don't realize that TPE is a reasonable operation, with the patient thereby missing the chance for cure? We need to pick out those patients.

Thank you for the opportunity of sharing this information with you.

THROMBOSTAT™ (THROMBIN, USP), a trusted hemostatic aid, is now available in a pump spray form—permitting flexible and easy application. With the new THROMBOSTAT pump, you can achieve hemostasis in seconds over large body surface areas. Each depression of the pump offers an even distribution

SPRAY ON HEMOSTASIS

of THROMBOSTAT solution—allowing uniform hemostasis of the total area. The THROMBOSTAT pump is available in a convenient sterile kit that features a 20,000-unit vial of THROMBOSTAT (a practical size for procedures involving capillary bleeding), an appropriate measure of diluent, and a pump sprayer cap. The kit offers sterile packaging—permitting the entire contents to be brought directly into the sterile field. With the new THROMBOSTAT kit, it has never been simpler to control capillary bleeding.

Please see next page for brief summary of prescribing information.

ADDRESS

CITY STATE ZIP

THROMBOSTAT™ (THROMBIN, USP) (Bovine Origin)
Before prescribing, please see full prescribing information. A Brief Summary follows:

Thrombostat must not be injected! Apply on the surface of bleeding tissue as a solution or powder.

INDICATIONS AND USAGE: Thrombostat (Thrombin, USP) is indicated as an aid in hemostasis wherever oozing blood from capillaries and small venules is accessible.

In various types of surgery solutions of Thrombostat may be used in conjunction with Absorbable Gelatin Sponge, USP for hemostasis.

CONTRAINDICATIONS: Thrombostat is contraindicated in persons known to be sensitive to any of its components and/or to material of bovine origin.

WARNING: Because of its action in the clotting mechanism, Thrombostat must not be injected or otherwise allowed to enter large blood vessels. Extensive intravascular clotting and even death may result. Thrombostat is an antigenic substance and has caused sensitivity and allergic reactions when injected into animals.

PRECAUTIONS: General: Consult the absorbable gelatin sponge product labeling for complete information for use prior to utilizing the thrombin-saturated-sponge procedure.

Pregnancy—Teratogenic effects: Pregnancy Category C. Animal reproduction studies have not been conducted with Thrombin, Topical (Bovine). It is also not known whether Thrombin, Topical (Bovine) can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Thrombin, Topical (Bovine) should be given to a pregnant woman only if clearly indicated.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: An allergic type reaction following the use of Thrombostat for treatment of epistaxis has been reported. Febrile reactions have also been observed following the use of Thrombostat in certain surgical procedures but no cause-effect relationship has been established.

DOSAGE AND ADMINISTRATION: General: Solutions of Thrombostat may be prepared in sterile distilled water or isotonic saline. The intended use determines the strength of the solution to prepare. For general use in plastic surgery, dental extractions, skin grafting, neurosurgery, etc, solutions containing approximately 100 units per ml are frequently used. For this, 10 ml of diluent added to the 1000 unit package is suitable. Where bleeding is profuse, as from cut surfaces of liver and spleen, concentrations as high as 1000 to 2000 units per ml may be required. For this the 5000 unit vial dissolved in 5 ml or 2.5 ml respectively, of the diluent supplied in the package is convenient. Intermediate strengths to suit the needs of the case may be prepared by selecting the proper strength package and dissolving the contents in an appropriate volume of diluent. In many situations, it may be advantageous to use Thrombostat (Thrombin, USP) in dry form on oozing surfaces.

Caution: Solutions should be used the day they are prepared. The solution may be used for up to 6 hours when stored at room temperature; up to 24 hours when stored under refrigeration, and, if necessary, up to 48 hours when stored frozen.

The following techniques are suggested for the topical application of Thrombostat.

1. The recipient surface should be sponged (not wiped) free of blood before Thrombostat is applied.
2. A spray may be used or the surface may be flooded using a sterile syringe and small gauge needle. The most effective hemostasis results when the Thrombostat mixes freely with the blood as soon as it reaches the surface.
3. In instances where Thrombostat in dry form is needed, the vial is opened by removing the metal ring by flipping up the plastic cap and tearing counterclockwise. The rubber-diaphragm cap may be easily removed and the dried Thrombostat is then broken up into a powder by means of a sterile glass rod or other suitable sterile instrument.
4. Sponging of treated surfaces should be avoided in order that the clot remain securely in place.

Thrombostat may be used in conjunction with Absorbable Gelatin Sponge, USP as follows:

1. Prepare Thrombostat solution of the desired strength.
2. Immerse sponge strips of the desired size in the Thrombostat solution. Knead the sponge strips vigorously with moistened gloved fingers to remove trapped air, thereby facilitating saturation of the sponge.
3. Apply saturated sponge to bleeding area. Hold in place for 10 to 15 seconds with a pledget of cotton or a small gauze sponge.

Thrombostat Kit: Thrombostat Kit contains one sterile 20,000 unit vial of Thrombostat, one sterile vial of Isotonic Saline Diluent, and one sterile pump sprayer cap. The Kit may be used as follows:

1. Remove the Tyvek blister lid by pulling up at the indicated corner. The sterile inner tray can be lifted out or introduced into the operating field.
2. The cover to the sterile inner tray is removed by pulling up on the finger tab, exposing the sterile contents.
3. Thrombostat solution of the desired strength is prepared and the pump sprayer cap inserted and seated on the Thrombostat solution vial. Note: Several strokes of the pump sprayer will be required before the Thrombostat solution is expelled.
4. Alternatively, when Thrombostat in dry form is needed, the vial is opened as described above and the dried Thrombostat broken up into a powder by means of a sterile glass rod or other suitable sterile instrument.

Factors Improving Survival in Multisystem Trauma Patients

JOSEPH A. MOYLAN, M.D., KEVIN T. FITZPATRICK, P.A.-C., A. JAMES BEYER III, and GREGORY S. GEORGIADE, M.D.

From Duke University Medical Center, Durham, North Carolina

This report analyzes the effect of air *versus* ground interhospital transport on survival following multisystem injury. There were 136 air-transported patients *versus* 194 ground-transported patients. The groups were similar in trauma scores, ages, mechanism of injury, and organ systems injured. There was a statistically significant survival advantage for air-transported patients with trauma scores between 10 and 5 (82.8% survival *vs.* 53.5%, p = < 0.001). The time interval between accident and admission to the authors' institution was similar for both groups. Important therapeutic interventions contributing to better survival by the air-transported group included higher incidences of endotracheal intubation (50% *vs.* 25%), blood transfusions (32% *vs.* 10%), larger volumes of electrolyte fluid (3.3 L per patient *vs.* 2.1 L per patient) as well as the use of MAST trousers (60.3% *vs.* 34.9%). Transport charges for both ground and air services were similar. However, helicopter charges met only 15% of the operational budget of the aeromedical service. The remainder of the costs were generated from hospital patient revenues. Overall, total hospital charges were similar for both groups and were influenced by the variability of length of stay, particularly for orthopedic patients.

MORTALITY RATES from major trauma have been shown to be significantly improved by rapid access to definitive care, particularly during the "golden hour" following injury. Many variables affect mortality rate during the initial phase of care including the availability of highly trained emergency medical technicians (EMTs) to care for the trauma patient both at the scene and during transport, as well as the specialized health care personnel and resources available at trauma centers. During wartime the helicopter has been instrumental in improving survival by providing rapid transport of the injured soldier to medical care.[1] The role of the helicopter in civilian trauma continues to be questioned.

There are two missions for aeromedical transport: scene response and interhospital transportation.[2] Reports from helicopter-based services show that advanced trauma life-support procedures were performed frequently at the scene of accidents with low morbidity rates.[3] However, only a single report comparing air *versus* ground transportation shows better survival for trauma patients treated and transported by helicopter from the scene of the accident.[4] In rural states, the majority of patients treated at major trauma centers have their initial medical treatment begun at an emergency department nearest to the scene of the accident and are then referred to the trauma center. In this type of trauma practice, the helicopter is most frequently used to transport critically injured patients from outlying hospitals to a tertiary trauma facility. The focus of this study is the comparison of the impact of helicopter *versus* ground ambulance on interhospital transportation of severely injured patients.

Methods

All patients with trauma scores of 12 or less, excluding local accident victims, admitted to the Duke University Medical Center Trauma Service beginning in 1985 were separated into either helicopter or ground transport groups and matched by trauma score comparing mechanisms of injury, age, systems traumatized, Glasgow scores, and mortality rate. Patients with complete referring hospital and transport records were reviewed to compare changes in physiologic status during transport and interventions prior to arriving at Duke Medical Center, which may have affected outcome in both groups. Ambulance charges, helicopter charges, and costs as well as total hospital charges were also evaluated for the air and ground groups.

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

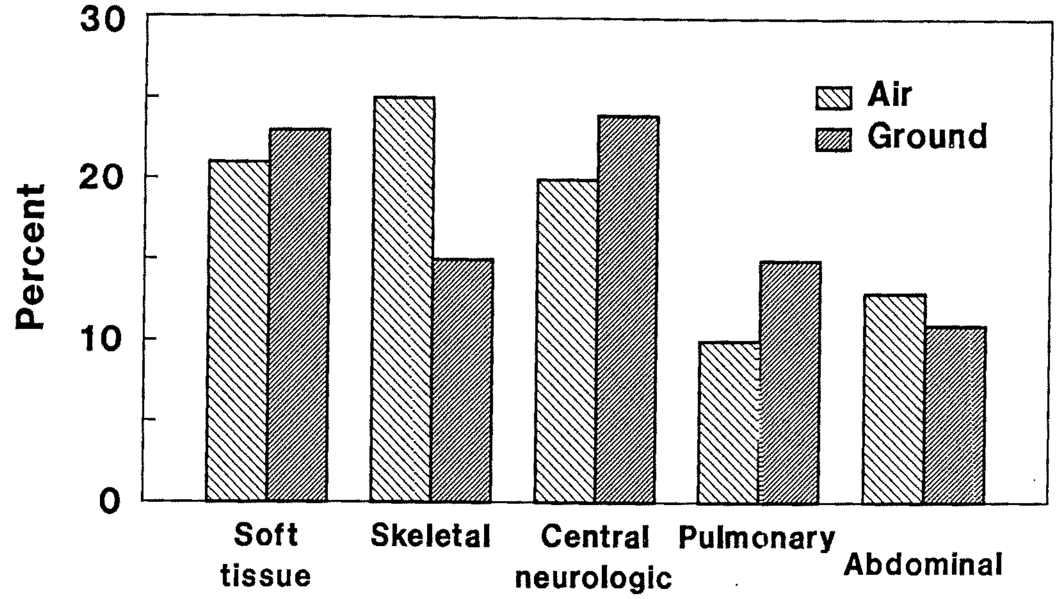

FIG. 1. Systems analysis of air- *versus* ground-transported patients.

Results

Records of 330 patients with trauma scores of 12 or less admitted to the Duke Trauma Service were reviewed. One hundred thirty-six patients were transported by helicopter while 194 patients were transported by ground ambulance. The air group had a mean age of 31.4 years and a mean trauma score of 8.7, while the ground group had a mean age of 33.4 years and a mean trauma score of 9.2. Glasgow coma scores were 8.6 for the air group *versus* 10.6 for the ground group. In the ground group 76% were injured in motor vehicle or industrial accidents and the remainder were assault victims. Of patients transported by helicopter, 85% incurred motor vehicle or industrial trauma while 15% were assault victims. The frequency of organ systems injured are shown in Figure 1. The average number of organs injured per patient was 1.9 for the ground group and 2.1 for the air group. Overall survival rates by trauma score are shown in Table 1. A statistically significant survival advantage for air transport was documented for patients with trauma scores between 10 and 5. In this group, there were 101 ambulance transport and 64 helicopter transport patients with a survival rate of 53.5% (54 of 101) and 82.8% (53 of 64), respectively (p = <0.001). Mean trauma scores for nonsurvivors was 4.1 for the air group and 7 for the ground group.

TABLE 1. *Overall Survival*

Trauma Score	Air	Ground
12–10	78 (97.4)	92 (92.3)
9–7	16 (81.3)	46 (47)
6–4	19 (63)	36 (27)
3–0	23 (15)	20 (5)
Total	136 (89)	194 (61)

Percentages are given in parentheses.

Ninety-six patients of 194 transported by ground had complete referring hospital and ambulance records, which were compared to the records of 136 air-transported patients to define important parameters affecting improved survival in the helicopter group. In this subset, 23% of the ground group were assault victims *versus* 15% in the helicopter group. Mean ages and trauma scores were comparable (13.4 air *vs.* 30.6 ground and 8.7 air *vs.* 9.2 ground). Systems injured analyses are shown in Figure 2. The average number of systems injured per patient were 2.1 for the air group and 2.2 for the ground group. Survival rates for each trauma score grouping were similar to the overall group (Table 2).

Therapeutic interventions prior to arrival at the hospital for each type of interhospital transport are shown in Table 3. Of the 46 patients aerovacuated to the hospital requiring urgent blood transfusions, 40 had their units started by the flight team at the referring hospital or during transport. Only ten (10.5%) of the ambulance group transported from outlying hospitals received blood prior to arrival at the hospital, although 26% of the ground group required blood urgently upon arrival at the Duke Emergency Department. Sixty of 68 patients (88%) in the helicopter transport group requiring airway intubation had their endotracheal tubes placed under the direction of the flight team at the referring hospital or in transport. Only 11 of 24 ground transport patients (47%) requiring urgent endotracheal intubation were intubated prior to arriving at the hospital. The remaining 13 patients required emergency endotracheal intubation by the hospital's trauma service due to airway complications. No patient in the air transport group had deterioration in their vital signs during the transport

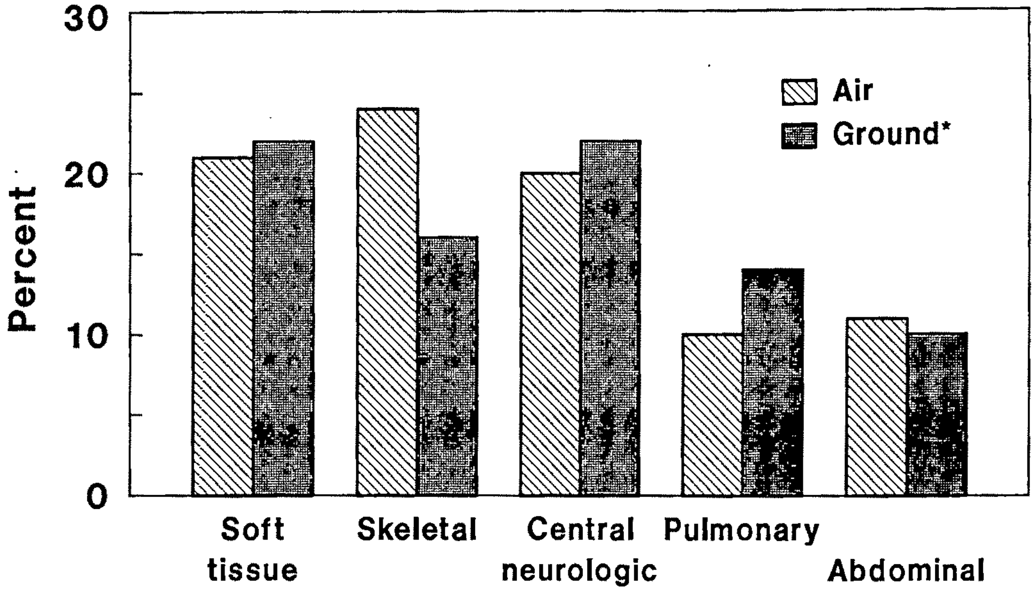

FIG. 2. Systems analysis of multisystem trauma patients.

phase between the referring hospital and Duke while 43% of the ground transport group became hemodynamically unstable. The average total time from occurrence of injury to arrival at the hospital was slightly longer for the air group (182 minutes *vs.* 175 minutes).

Transport charges for both types of services included a base charge plus a per mileage fee, which were billed to the patients. Life Flight helicopter charges averaged 15% more than the ground ambulance; however, the charges for helicopter service covers only 15% of the operational cost. Ground ambulance organizations were able to operate with a balanced budget or are dependent on local charitable donations. Total hospital charges were similar for both groups ($26,000 ground *vs.* $23,858 air). Separation of charges by trauma scores were also similar: trauma scores of 1–4 ($23,717 air *vs.* $30,965 ground); trauma scores 5–8 ($22,828 air *vs.* $24,863 ground); trauma scores 9–12 ($21,525 air *vs.* $19,603 ground).

Discussion

Survival following multisystem injury has improved over the past decade with the development of organized emergency medical service systems. Many factors of this system including designation of trauma centers, advanced prehospital care, communications systems, and better technology in the treatment of multisystem injury influence these improved statistics. Prehospital services vary from urban areas where paramedic level EMTs provide care to more rural areas which vary from basic EMT to EMT-intermediate level care. The impact of EMT prehospital care on survival is still being evaluated. Alexander et al.[5] showed improved survival from care provided by paramedic level EMTs in motor vehicle trauma patients while Boyd et al.[6] demonstrated no difference in survival between care given by basic or advanced EMTs. The utilization of ground ambulances during wartime was associated with delayed access to initial surgical treatment for the injured soldier. Military experience with helicopters has demonstrated progressively lower mortality rates with serious injury supporting the concept of shorter time intervals between injury and effective surgical care as the important factor in this improved survival.[7] Additional benefits of rapid air transport on the battlefield were lower morbidity rates, improved limb salvage, and shortened hospitalization. Civilian experience with helicopter transport for scene response has not been able to demonstrate survival differences. While many reports attest to the improved level of care provided by flight teams who are trained in Advanced Trauma Life Support and Advanced Cardiac Life Support procedures, the value of this alternate

TABLE 2. *Survival of Patients with Complete Prehospital Records*

Trauma Score	Air	Ground
12–10	78 (97.4)	48 (97.9)
9–7	16 (81.3)	18 (62.5)
6–4	19 (63)	15 (40)
3–0	23 (15)	15 (12)
Total	136 (89)	96 (74)

Percentages are given in parentheses.

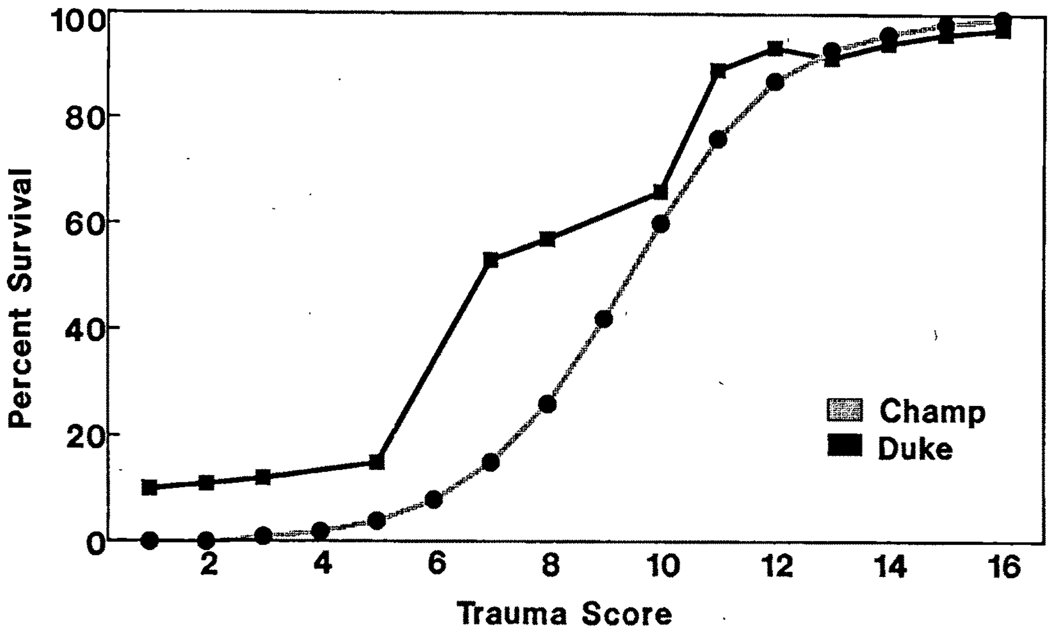

FIG. 3. Duke *versus* Champion[8] predicted survival by trauma score.

method of prehospital transport has been seriously challenged. Only a single report comparing transportation of a large volume of trauma patients from the scene of the injury has shown an improved survival over predicted mortality rate for the air *vs.* ground transportation.[4]

Trauma centers with organized trauma services, outreach educational programs, and trauma registries for outcome analysis provide a multifactorial approach to better trauma care. Level I trauma centers such as Duke University Medical Center, which has a trauma registry containing over 2000 patients, have shown favorable survival statistics compared to the national experience such as shown by Champion[8] (Fig. 3). While the basic principle of triage is to transport the patients with serious multisystem injury to a trauma center, rural states with extensive distances between trauma centers are not suited to this approach. Patients are most commonly taken to the nearest hospital where their initial treatment is provided. Those needing specialized trauma care in a Level I trauma center then require a second transport to the tertiary care center. The rural practice of trauma care is different from that of urban trauma centers with a twofold increase in mortality rates for specific motor vehicle injuries.[9] In this setting the helicopter is utilized primarily for interhospital transportation of critically injured patients rather than scene response.

Duke Trauma Center, centrally located in North Carolina, receives over 75% of multisystem-injured patients shortly after having their treatment begun at other outlying hospitals. With the initiation of the helicopter program, it was possible to compare the impact of air *versus* ground transportation on survival for referred trauma patients. A trauma score of 12 or less was selected for this study because these lower trauma scores reflect serious injuries associated with increased mortality rates. The study group included over 300 air- or ground-transported patients who were similar in age, trauma scores, mechanism of injury, and systems injured. There was significantly better survival advantage for severely injured patients with trauma scores between 10 and 5 who were transported by helicopter. The survival in the midrange trauma scores (10–5) was 82% for the air transport group and 53% for the ground transport group. While there were more survivors with trauma scores of 4 or less in the aerovacuation group, no statistical advantage could be attributed to helicopter transportation because of the small numbers of patients.

Survival for injured patients with trauma scores of 11 or higher was excellent for both groups. There was no advantage for aeromedical transport for these patients. This points out the need for careful triage prior to dispatching the helicopter, especially for busy helicopter programs where availability of the helicopter may be limited.

Lower mean trauma scores for nonsurvivors in the air *versus* the ground transport group is another indicator of the impact of care provided during transport. In order to define the factors influencing improved survival for patients with midrange trauma scores, the hospital records of those ground transport patients with complete documentation to compare to the air transport group were utilized. Approximately one-half of the ground transport group arrived at the Duke emergency department with complete documentation of the accident and treatment received at the referring hospital. The remaining records of the ground ambulance group lacked key information on the treatment prior to admission to the Duke Hospital. This subset of ground-transported patients were similar in terms of types, numbers of organ systems injured per patient, mechanism of trauma, ages, and trauma scores.

The time interval from scene of accident to admission to the hospital was similar for both ground and air transport groups, indicating that other factors are important in improved survival for the aeromedical group. Therapeutic interventions including blood transfusions, endotracheal intubation, and the use of Medical Antishock Trousers were significantly more frequent in the air-transported group. Of patients requiring intubation because of significant head and neck or chest trauma, 88% of the intubations were placed under the direction of the flight team prior to arrival at the hospital. Only 47% of the ground ambulance patients requiring intubation had their endotracheal tubes placed prior to arrival at the hospital. Significantly higher percentages of the air-transported group had blood administered prior to arrival at the hospital under the direction of the flight team. In addition, Medical Antishock trousers were more frequently employed in the air-transported group. The aerovacuated patients received a larger electrolyte resuscitation during transport and prior to arriving at the hospital.

The impact of utilization of the Life Flight personnel with critical care training under direct medical supervision had a beneficial effect in that no patients in the air-transported group had deterioration of their vital signs during the transport phase from the referring hospital compared to 43% of the ground group, which did become more hemodynamically unstable. The Life Flight helicopter program carries O– blood on interhospital transports as well as utilizes any blood that is crossmatched at the referring hospital. The flight personnel are skilled in endotracheal intubation as well as other advanced cardiac and trauma life-support techniques. Ventilatory support including the capability of providing PEEP and continuous suction for chest tubes can be provided during air transport. The availability of constant medical supervision via radio and telemetry made other pharmacologic interventions possible during aeromedical transport including treatment of hemorrhagic or cardiogenic shock, dysrhythmias, or increased intracranial pressure from head injuries.

The charges for the helicopter service billed to the patients were similar to ground charges in the area. The establishment of the charges for the helicopter were determined by many internal factors in the medical center. These charges, however, only met 15% of the operational expenses of the helicopter service. The remainder of the operational costs were generated by revenue from inpatient hospital charges and represents an institutional commitment to trauma care. No difference in hospital charges including breakdown by trauma scores could be found between the two groups. These results may be influenced by variables in length of stay, especially in patients with long bone fractures. A larger series of patients may show a favorable financial impact of the helicopter service on patient care.

In summary, analysis of the Duke experience in the helicopter transport of multisystem trauma patients demonstrates that an organized systems approach to trauma care improves survival. In the rural setting, interhospital helicopter transportation provides a lower mortality rate by the prompt extension of Level I trauma center resources and expertise to the primary care hospital rather than by shortened intervals between injury and admission to the trauma center. Aeromedical transportation provided hemodynamic stability and physiologic support in the resuscitation phase of trauma care. Interhospital helicopter transportation was most beneficial to trauma patients with midrange trauma scores between 10 and 5. While charges generated by helicopter transport do not meet operational expenses, these operational deficits were met from hospital patient revenues associated with improved survival.

DISCUSSION

DR. BASIL A. PRUITT, JR. (Fort Sam Houston, Texas): Dr. Moylan, Dr. Georgiade, and their colleagues have demonstrated the importance of stratifying patients by injury severity when assessing outcome, and have presented data indicating that a significantly higher percentage of injured patients with trauma scores between 10 and 5 survived when their interhospital transfer to a Level I trauma center was by helicopter as compared to ground ambulance.

These authors have found that time between the injury and the admission to the trauma center was not influenced by the means of transfer, but that the means of transportation influenced the level of prehospital care applied to the patient. That is, endotracheal intubation, application of MAST trousers, infusion of blood, and the rapid infusion of intravenous fluids in general could be carried out by flight team personnel prior to and during the aeromedical transfer.

In short, the earlier application of trauma center-directed care appears to be more important than rapidity of patient movement.

The author's experience mirrors that of the U.S. Army Institute of Surgical Research in the aeromedical transfer of literally thousands of burn patients—in which experience we have found that a large percentage of the patients require management of catheter problems, alterations in ventilatory management, or alteration of fluid therapy by the surgeons of our burn teams, either prior to or during flight.

Since speed of transfer doesn't seem to be a significant factor in the outcome of these patients, but prompt institution of trauma center-guided therapy does, do the authors feel that education of and improved communication with their referral sources would improve the level of care given to the ground transport patients?

We insist on physician-to-physician communication before accepting burn patients for transfer, and I wonder whether the authors feel that this could be done in their system of trauma care and whether it would make a difference.

There are several questions the answers to which will assist us in evaluating the authors' conclusions. Since the outcome of a population of trauma patients is strongly influenced by central nervous system injury, it is of concern that a greater percentage of the ground-transported patients, as indicated in both Tables I and II, had CNS involvement, and one wonders what role that played in the observed outcome.

It is puzzling that, with the higher incidence of CNS injury, the ground-transported patients had a higher Glasgow trauma score, and I ask the authors how they might explain that apparent paradox. Since the trauma score may change with time, I also ask the authors whether the postinjury time of trauma score determination was comparable in the two groups of patients.

The authors state that the charges for air medical transfer represented only 15% of costs and that the remaining 85% were subsidized by other inpatient revenues as a most laudable institutional commitment to trauma care. That is, as the authors suggest in their manuscript, a strong argument for improved triage, since 74% of the air-transported patients had trauma scores above 9 or below 4, and outcome in those patients was not influenced by the means of patient transport. Do the authors have a plan to improve triage accuracy within their system?

I compliment the authors on this important study that redirects misplaced emphasis from speed of patient movement by air transport, and demonstrates the advantage of transporting an extension of the emergency center to the injured patient.

As a final question, I ask the authors if they plan to take the next step and include a surgeon in their trauma flight teams?

DR. GEORGE F. SHELDON (Chapel Hill, North Carolina): I enjoyed the paper very much. As we at the University of North Carolina are 8 miles away and back each other up when helicopters develop their inevitable mechanical problems, we see many of the same problems. Dr. Moylan's paper, among other things, proves the value of excellent prehospital control of transport. It documents the value of the skilled flight attendants and nurses that work with Drs. Moylan, Georgiade, and the Duke team.

With only four Level I trauma centers in the state and because most of our hospitals are small and lack the resources to care for the multiply injured patient, the helicopter is needed in North Carolina. Moreover, Susan Baker recently reported that for comparable levels of injury severity score (ISS), mortality rates in rural areas are four times that of patients having the same injury in urban areas.

I would add an interpretation of the data presented by Dr. Moylan. I think the greater time spent in the hospital prior to transport may represent local evaluation and resuscitation time. The problem everyone is addressing is availing the resources of the Level I center to patients within the golden hour.

As someone who is not very enthusiastic about MAST trousers, I would also ask if you have data or strong conviction that MAST trousers have improved outcome. I recognize this is a debatable area.

The last question is philosophical (Slide). Dr. Warren Cole of this Association pointed out a problem that we are going to see more of as we develop sophisticated Level I centers. He pointed out (in 1957) that the mechanisms for obtaining training in trauma are so inadequate that care should be given to development of training programs in the field. We now train 2,750 surgeons a year; 400 remain in general surgery. Level I requirements for directors are that there be general surgeons to direct the trauma teams as Level I leaders. I think one of the exceptions is Dr. Georgiade at Duke, who is a plastic surgeon deeply involved in the trauma transport program.

My last question is, where will we get people to run trauma teams as you have done so well at Duke?

DR. C. WILLIAM SCHWAB (Philadelphia, Pennsylvania): Dr. Haynes and Jones: I rise to compliment the authors on their observations. It is always nice to hear a paper that supports your prejudice. In 1983 we reported a similar study. Unfortunately, we did not have data to look at outcome, but we did notice that helicopters were bringing in sicker people (higher ISS, lower TS) and that these people were surviving. I have several questions for Dr. Moylan.

I take some issue with your methodology and, in particular, your heavy reliance on trauma score as the only barometer of the severity of injury. Why didn't you use the Injury Severity Score and, specifically, why not include a breakdown of the Abbreviated Injury Score (AIS)? Our own observations have been that head injury, in and of itself, is not only the most lethal, but the most costly single injury seen at a trauma center. However, other combinations, particularly head and chest injury, carry a very high mortality and a high cost. It may have been important to see if anatomic injury correlated with cost.

(Slide) As to the economic issues Dr. Moylan introduced, I believe this paper offers too simple a view and, in fact, may be misleading. First of all, this slide shows the data from a 1-year study we performed in southern New Jersey at a state-designated Level I trauma center. It represents an experience with 523 patients (80% blunt MVA's) admitted to a single hospital that receives its entire reimbursement from a state-regulated prospective payment system (DRG). This system is similar to the reimbursement system used for federal medicare. Additionally, during the time that these 523 patients were admitted, prehospital anatomical triage guidelines were practiced by the EMS providers so that true regionalization was taking place. In essence, high severity patients were concentrated in this hospital. As you can see, the average stay was approximately 15 days, the mean ISS was 15.6, and when we compared cost and state reimbursement, we *lost* \$3562 on *every* admission. Also note from the slide, as severity of injury increased (higher ISS), so did hospital cost and also the economic loss!

Secondly, if we break out the outliers, as seen in this slide (outliers being defined as those patients that exceeded the normal length of stay for any given DRG), we lost an average of \$7200, twice that of all cases. Outliers tend to be the most severely injured patients, and, in our outlier group, 60% had an Injury Severity Score above 16. These patients tend to be those type of patients that helicopters, like those in Chapel Hill or Duke, bring into the medical center. Also notice the increasing loss per case, again correlating with higher ISS or severity of injury.

I realize that New Jersey is probably 5 to 6 years ahead of the United States with regards to its experience with prospective payment, and North Carolina obviously does not have the problem just yet. However, Dr. Moylan, I wonder whether if you were to scrutinize your financial data, would you find among your Medicare/DRG population an experience similar to ours in New Jersey? As prospective payment is adopted by the third party payers to solve the medical inflation problem, and as the elderly population continues to grow, this small hidden problem may come to dominate your fiscal officer's headaches. Our experience with prospective fixed reimbursement has led us to conclude that this is the greatest problem and challenge for future funding of any trauma center, helicopter or not.

Once again, I enjoyed the paper; and I thank the association for the privilege of discussing it.

DR. FRANCIS T. THOMAS (Greenville, North Carolina): Dr. Moylan has presented a very nice study of a patient group with trauma scores between 5 and 10. I think this is one of the first and best communications from a nonurban setting documenting this in a well studied group of patients.

Since Baron Larrey first introduced the ambulance, we have seen a movement towards a rapid transport system for patients, with the helicopter offering our latest option in this area. The "Golden Hour" concept is truly put to the test in a rural environment. The helicopter proliferation, as many of you know, has been exponential. This has resulted in the widespread distribution of hospital helicopters. In many states, the activity has been so intense that it has been referred to as the "helicopter wars."

I think that Dr. Moylan has shown us that there is, indeed, a strong medical rationale for the helicopter, not so much to decrease the time of transport of the patient, but rather to permit the more wide-spread use of field personnel that are highly trained and have the capability of a Level I Trauma Center. This expertise is brought to the patient at the accident site and continued on the way to the hospital.

I have two questions for Dr. Moylan. Joe, what do you feel are the appropriate and optimal distributions for this type of service and for Level I trauma centers? Do we need any more specialization? Does there need to be any redistribution of the type of resources and facilities available in any of them?

Secondly, what can we do to prevent the tragic helicopter crashes that we hear of all too often? Having been through one of these experiences at our hospital, I can tell you that the effect on the entire hospital staff is truly extraordinary.

DR. ARTHUR J. DONOVAN (Los Angeles, California): I had not intended to discuss this paper, but the question of funding for trauma care has been raised, and I rise to comment in that regard.

In Los Angeles, an area of 7 million people, a trauma system was established, with Level I trauma centers appropriately spaced. Within the last 2 years, six private hospitals have withdrawn from the system because of inadequate funding for patients without any or with inadequate payment capability. This has put an enormous strain on the remaining hospitals. Neither the state, the County, nor the Federal Government has been willing to address the issue of funding for the care of the trauma patient. This issue needs to be addressed.

DR. JOSEPH A. MOYLAN (Closing discussion): I appreciate all the discussants and their contributions to what we think is an important issue.

Dr. Donovan, we agree with you that funding is a major problem. The majority of our patients, as you observed, were motor vehicular trauma. In our state there is some mandatory collision insurance that covers some of these hospital charges.

Dr. Thomas, distribution of trauma centers is a sociopolitical problem that is very difficult to deal with. I am not sure I have an answer that I can present in the brief time we have here today.

Dr. Schwab, because we are focusing on the physiologic phase of their care during the first few hours, we chose to use the trauma score, although we do have the ISS and the AIS on all our patients. ISS and AIS are retrospective, based on anatomic injuries and are probably more important for comparing long-term hospitalization and finances. In distinction to New Jersey and the data that you reported, the inpatient revenues that covered our helicopter operation came from the trauma unit itself.

We experienced a budgetary surplus last year in our trauma unit, since most of our patients are not penetrating trauma and do have third party coverage.

Dr. Sheldon, we appreciate the comments you made about MAST trousers. We are also concerned about their hemodynamic value. I think that in many instances, the MAST trousers are used to stabilize long bone fractures. I am not sure what their hemodynamic value is.

In terms of time in the emergency room, we felt that in our series most doctors call us earlier for the helicopter, rather than later when they are transporting them by ground.

How trauma surgeons are going to be trained in the future will be determined by the committment made by general surgical training programs, and we all have to address that issue.

Dr. Pruitt, we do have a medical control officer who accepts every flight as does the Army Burn Center in San Antonio. We do find, however, that there is a gap between what you direct the referring doctor to carry out before you transport and what he actually does.

Again, the difference in the number of head injuries and the Glasgow is an important point, as you have observed. There were a few more head injuries in the ground group. However, they were less severe, as reflected by the higher Glasgow score.

We are not going to send a trauma surgeon on our flights. Basically, the interventions we have found important included intubation, the use of blood, and the placement of chest tubes. Our personnel are skilled in those things, and we do not feel we have the resources to expend a surgeon to do that.

The Capacity of Serum to Support Neutrophil Phagocytosis Is a Vital Host Defense Mechanism in Severely Injured Patients

HIRAM C. POLK, JR., M.D., CHRISTOPHER D. GEORGE, F.R.C.S., MICHAEL J. HERSHMAN, F.R.C.S.,
SAMUEL R. WELLHAUSEN, PH.D., and WILLIAM G. CHEADLE, M.D.

From the Price Institute for Surgical Research, Department of Surgery, University of Louisville School of Medicine, Louisville, Kentucky

The opsonic capacity of patient serum was studied in 43 trauma patients of whom 13 recovered uneventfully, 21 developed major infection, and nine died, mostly of infection. Blood samples were taken within 24 hours of injury. Fifteen patients were studied serially of whom 14 developed severe infection and/or died. Opsonic capacity was determined by flow cytometry and measured as the ability of normal neutrophils to phagocytose killed bacteria previously incubated with patient serum. The most dilute sera reflected changes for better and worse most clearly. On initial assessment, those who died of sepsis showed a 61% mean fluorescent intensity (MFI), which was significantly lower than the 99% MFI for those who survived infection ($p < 0.01$) and the 78% MFI of those who developed no infection ($p < 0.05$). Serial samples demonstrated a super serum response in four of seven patients surviving major sepsis but in none of the seven who died of infection.

TRAUMA IS A MAJOR CAUSE of both mortality and morbidity in this country.[1] Approximately one-half of trauma-related deaths occur at the scene of injury, and thus, accident prevention is the primary hope for reduction of these deaths. Of the patients who arrive at the hospital alive, one-half of those destined to die do so within the first few hours, usually from uncontrollable hemorrhage or closed head injury. The majority of the remainder of deaths and most major morbidity rates in those patients who survive initial resuscitation are due to infection.[2] Despite great improvements in surgical treatment, perioperative support, and broader antimicrobial usage,[3] infection remains a serious problem and plays a particularly decisive role in the trauma victim. Detailed analysis of a variety of host defense mechanisms has been performed as effective means to stimulate the depressed immune system in these patients continue to be sought.[4]

In an effort to determine which aspects of the immune system are most directly affected after trauma, a long-range study of a variety of parameters of both cellular and humoral immunity from severely injured patients was undertaken.[5] Of all parameters tested, the ability of peripheral blood monocytes to express HLA-DR and the ability of patient serum to support phagocytosis of bacteria by normal neutrophils were found to be of dominant importance. For convenience, the phrase, serum opsonic capacity, will be used in place of capacity of serum to support phagocytosis by normal neutrophils. Such severely injured patients were studied to determine if certain patterns of serum opsonizing capacity could be identified and to what extent these correlated with eventual clinical outcome.

It is well recognized that the ability of neutrophils to phagocytose bacteria is reduced following trauma.[6,7] However, major intrinsic polymorphonuclear leukocyte dysfunction in these patients has not been consistently shown. The impaired capacity of neutrophil phagocytosis may therefore be due to serum factors rather than instrinsic cellular defects.[8,9] A recent study found no difference between phagocytic indices of neutrophils from infected and nonseptic trauma patients,[10] and others have shown complement-dependent deactivation and damage of circulating neutrophils as well.[11] This paper reports a continuing study of the ability of sera from severely injured patients to support opsonization of bacteria for phagocytosis by normal donor neutrophils. The effects of both complement-dependent and

complement-independent serum opsonic capacity in badly hurt patients are further examined.

Materials and Methods

Patient Population

Forty-three consecutive patients admitted under the care of the emergency surgical services at the Humana Hospital-University of Louisville, KY, were studied. Only patients who had sustained major trauma resulting in an injury severity score (ISS) of at least 20 were accepted. To allow more meaningful comparisons between equivalent injuries in patients of different ages, the concept of expressing the ISS as percentage of the LD_{50} for age was used as originally described by Bull.[12] Using a probit fit analysis of burn mortality rates, Bull developed LD_{50} values for three separate age ranges. Individual percentages of LD_{50} values were calculated by dividing the ISS of each patient by the appropriate LD_{50} for age and expressed as a percentage (%LD_{50}). Patients with a previous medical history of myocardial infarction, organ failure, neoplastic disease, or current immunosuppressive therapy (steroids or cytotoxic drugs) were excluded. Patients transferred from other centers after initial stabilization were accepted; however, those transferred after prolonged care were excluded. Informed consent was obtained from the patient or relatives in all cases.

Patient outcome could be divided into the following three groups: (1) a good outcome group who did not develop major sepsis (N = 13); (2) a major sepsis group (N = 21); and (3) a group who died (N = 9). Seven of the nine patients who died did so in a septic state and usually with multiple organ failure. The other two died within 4 days of admission from progressive hypoxia. Major sepsis was described as every instance of bacteremia, all of which were associated with definable clinical problems, major wound infection, intra-abdominal or other serous cavity abscess, and any situation in which reoperation for suspected infection was undertaken.

Contamination present at the time of admission or surgery was graded as follows: massive soft-tissue contamination or large bowel spillage (2+), minor soft-tissue, intrathoracic, or abdominal contamination (1+), or no contamination. Venous blood samples were obtained from each patient within 24 hours of admission. There was insufficient serum from one patient who died to carry out the heat inactivated analysis. In addition, 15 patients had serial serum samples taken approximately every 3 days throughout their hospital stay. These patients were selected on the basis of a high likelihood of developing severe infection from their initial clinical presentation. Another patient who developed necrotizing mycofasciitis and died with chronic sepsis was also serially studied.

Serum Opsonic Capacity

Individual serum samples were tested for their ability to opsonize *Staphylococcus aureus* for phagocytosis by neutrophils obtained from a normal volunteer. Formalin-killed bacteria were stained with a fluorescent dye (Texas red). The stained bacteria were incubated for 30 minutes at 37 C with dilutions of test serum or control pooled human serum. A paired aliquot of serum was heat inactivated at 56 C for 45 minutes to determine whether the opsonic capability of the serum was complement-dependent.

The bacteria were washed and incubated for 30 minutes at 37 C with the normal leukocytes. Each sample was then washed and fixed in paraformaldehyde. Phagocytosed bacteria were detected using a cytofluorograph II flow cytometer (Ortho Diagnostics, Westwood, MA).

Data were recorded as the mean fluorescent intensity emitted from neutrophils, which ingested one or more bacteria. Mean fluorescent intensity was expressed as a percentage of control values obtained by using pooled human serum (%MFI). Two thousand neutrophils were analyzed in each sample.

Statistical Analysis

The Student's t-test was used to determine differences between patient outcome groups. Wilcoxon ranking sum test was used to determine differences in the degrees of contamination on admission between the groups with uneventful recovery, major infection, and those who died. Differences were considered significant at $p < 0.05$.

Results

The mean ISS of the patients was 35.7, and the mean %LD_{50} was 102. The median contamination of the uneventful recovery group was 0, which was significantly less than both the septic group (median: 1) and the dead group (median: 2). The respective means were 0.38, 1.24, and 1.44 of the three clinical outcome groups. The differences between the septic and dead groups were not significant. Initial total serum %MFI values are shown in Table 1. The group who ultimately died had initial %MFI values significantly less than both the septic and good outcome groups at serum dilutions of 0.5 and 5.0%. Although the differences at 1.0 and 10.0% serum dilutions did not reach statistical significance, the trend was similar. This reduced capacity for opsonization in patients who ultimately died was even more clearly seen

in heat inactivated serum (Table 2). The group of patients who died had heat inactivated %MFI values significantly less than both the septic and good outcome groups at all serum dilutions analyzed.

The most dilute sera reflected the most widely varying opsonic capacity changes. Septic patients had greater total %MFI values than nonseptic patients (Table 1) but did not display greater heat inactivated %MFI values except in the dilute serum (0.5%, Table 2). The difference in serum opsonic capacity between septic and nonseptic patients was determined by subtracting the mean %MFI value of nonseptic patients from the mean %MFI value of septic patients at each serum dilution (Fig. 1). This was also calculated for the septic and dead patients. The differences in total %MFI were seen most clearly at the lowest dilutions. This curious observation that the most dilute sera consistently reflected opsonic capacity changes most clearly was also seen in the serially followed patients. Furthermore, it reflected both beneficial and detrimental changes. Two examples emphasize this. A 27-year-old man sustained a shotgun wound to the abdomen and bony pelvis. He developed intra-abdominal sepsis and osteomyelitis but survived these infections. The 0.5% serum dilution consistently reflected the highest %MFI detected throughout his illness (Fig. 2). At the opposite end of the spectrum was a 62-year-old woman who sustained severe blunt chest trauma and multiple extremity fractures. She developed adult respiratory distress syndrome and chronic refractory pneumonia from which she ultimately died 157 days after injury. Her 0.5% serum dilution was consistently the lowest %MFI that was detected throughout her hospital course (Fig. 3).

The patient data, outcome, and opsonic capacity changes are summarized in Table 3. The observation that patients who survived sepsis tended to have elevated %MFI values led to characterization of a super serum response, which occurred when %MFI values exceeded 150% of normal pooled human serum. An example is shown in Figure 2. This super serum response

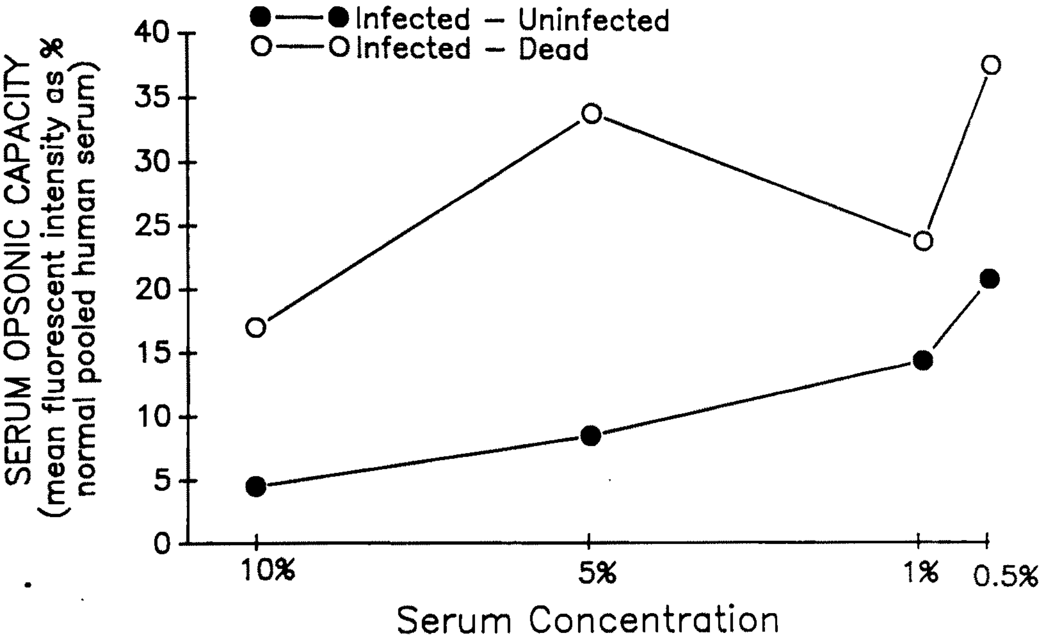

FIG. 1. The relationship between serum concentration and the differences in opsonic capacity (%MFI) of both those who developed sepsis and those who died, and those with sepsis and those who recovered uneventfully.

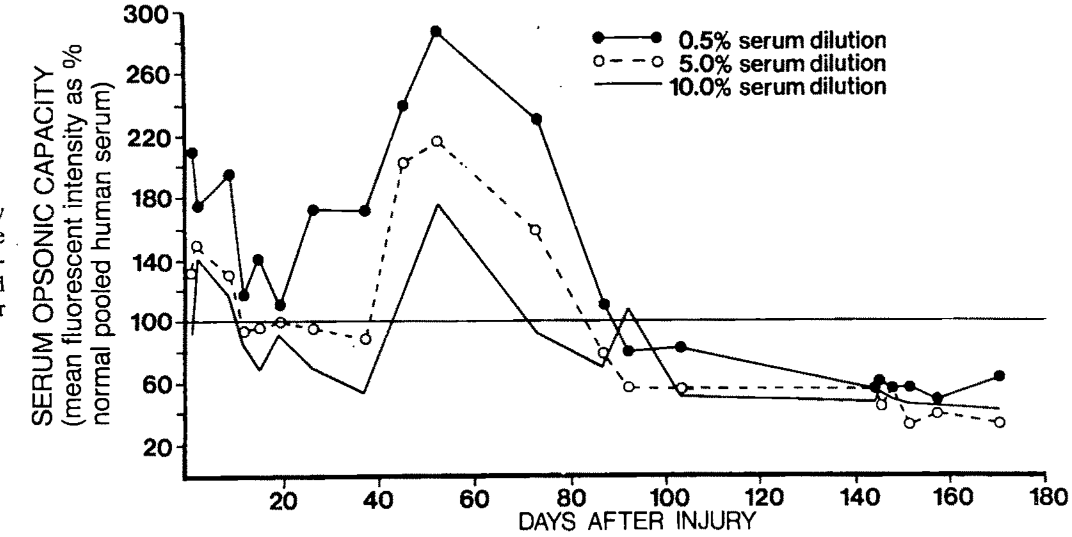

FIG. 2. Opsonic capacity (%MFI) at three separate serum dilutions as a function of time in a 27-year-old man who survived major infection.

occurred in four of seven patients surviving major sepsis and in none of the seven who died of infection.

Heating serum at 56 C for 45 minutes eliminates complement-dependent phagocytosis and also serves as an internal control for the process. Both the patient with necrotizing fasciitis and the one trauma patient who died from chronic infection demonstrated similar opsonic capacity changes, which were not seen in any patients who survived sepsis. These changes included a progressive depletion of total %MFI values together with unchanged heat inactivated %MFI (Fig. 4), indicating depletion of complement-dependent opsonic components, a phenomenon previously referred to as "consumptive opsoninopathy."[13] Note also the relative stability and/or protection of intrinsic complement-independent opsonic activity.

Discussion

Reduction in both serum opsonic capacity and opsonin levels has been shown to occur immediately following major trauma, but only variable correlation with subsequent infection has been documented.[14-17] Replacement of depleted opsonic fibronectin has been shown to restore serum opsonic capacity utilizing radioisotope techniques,[18] but correlation with clinical outcome has not been done. These results demonstrate a significant correlation between initial serum opsonic ca-

pacity and ultimate death associated with infection for both total and heat inactivated serum. Patients who ultimately died had significant reduction of both complement-dependent and noncomplement-dependent opsonic capacity. Furthermore, markedly reduced opsonic capacity within 24 hours of injury was predictive of death at a time well before the onset of clinical sepsis. Interestingly, a recent report,[19] using an entirely different method to assay neutrophil function, also concluded that serum factors are substantially responsible for some diminished neutrophil activity following general anesthesia and elective operation.

In patients who made uneventful recoveries, the total serum opsonic capacity was reduced, but the complement-independent opsonic capacity remained normal. It appears then that major trauma primarily affects complement-dependent opsonic capacity. In contrast, patients who developed major sepsis but survived had both normal total and heat inactivated capacity. Thus, the ability to restore subnormal complement-dependent serum opsonic capacity to normal appears to be a beneficial host defense mechanism in those who develop infection.

The ability to increase serum opsonic capacity was beneficial in serially studied patients. Twelve patients developed major infections and five died from such infection. Six of the seven who survived major infection dealt with their infection well initially, and all of these were able to increase their opsonic capacity. Four of them increased the total opsonic capacity to greater than 150% of normal, defined as super serum. One patient (Fig. 2) produced a %MFI as high as 300% of normal during his infection before he recovered. In contrast, inability to increase opsonic capacity in the face of infection was detrimental. No patient who died increased his opsonic capacity to the super serum range, and most actually had a downward trend. One patient who developed a consumptive opsoninopathy (Fig. 4) had severe reduction in complement-dependent opsonic capacity but normal heat inactivated opsonic capacity. This phenomenon did not occur in any other of our trauma patients. Such changes were seen, however, in another

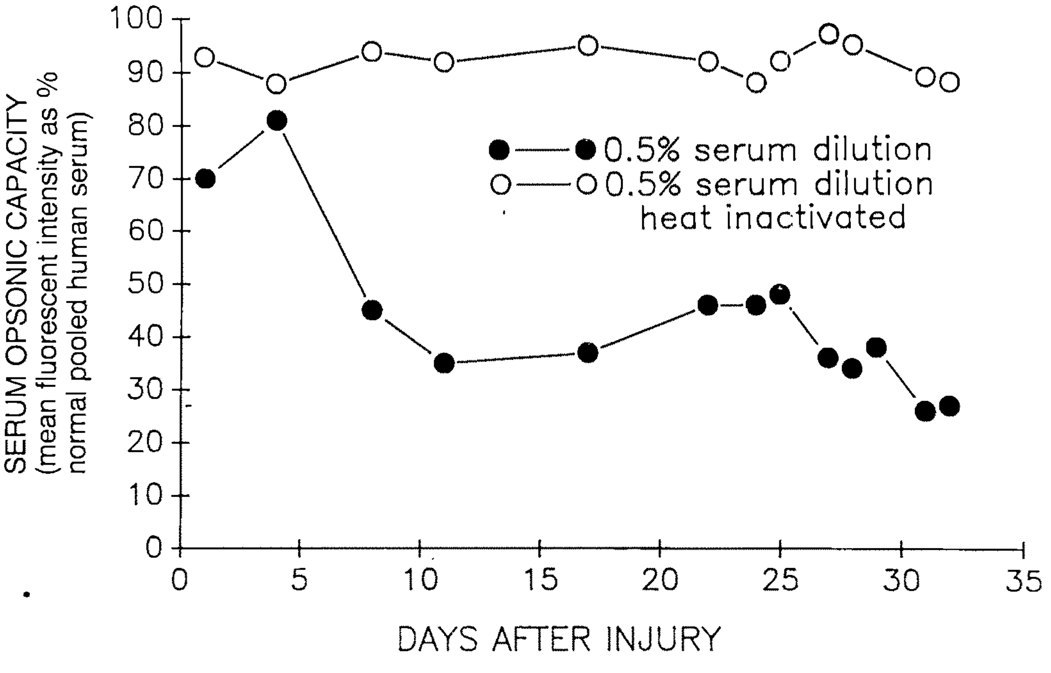

FIG. 4. Mean fluorescent intensity of both total and heat inactivated serum as a function of time in a patient with consumptive opsoninopathy. The total opsonic capacity is expressed as a percentage of normal non-heat inactivated pooled human serum. In contrast, heat inactivated serum opsonic capacity is expressed as a percentage of heat inactivated normal pooled human serum.

patient with necrotizing fasciitis who eventually died of his infection.

The most dilute serum most clearly reflected opsonic capacity changes whether beneficial or detrimental. Considering day 1 samples, the difference in opsonic capacity between surviving patients who developed sepsis and those who died as well as those with uneventful recoveries was most pronounced at the lowest dilutions, as seen in Figure 1. Dilution of certain inhibitors of opsonization might explain this phenomenon in certain situations, such as the patient represented in Figure 2. Such inhibitors have been previously identified[20,21] and are common manifestations of competitive inhibition at receptor sites. Levels of suppressor active peptide have been found to be significantly elevated in burn patients who died compared to those who survived.[22] The importance of dilution was seen not only at the initial measurements but also serially; however, it is not clear why the patient who eventually died (Figure 3) would have the lowest values represented by the most dilution. The trend of the most dilute sample reflecting the greatest difference held up for both total and complement independent opsonic capacity.

Clearly, severity of injury, age, and degree of bacterial contamination at the time of injury are major factors in determining clinical outcome of the trauma patient.[23] In this study, the importance of bacterial contamination as a determinant of outcome and opsonic capacity changes was observed. Patients destined to make uneventful recoveries, develop major sepsis, and die had median degrees of contamination of 0, 1, and 2, respectively. The higher initial levels of total opsonic capacity seen in septic compared to nonseptic patients (Table 1) may be related to greater bacterial challenge. Interestingly, serum opsonic capacity changes bore no relationship to monocyte HLA-DR expression, which independently distinguished between different clinical outcomes.[5] Similar to the prediction of septic death by the first determination of serum opsonic capacity, the first monocyte HLA-DR result also was predictive of death and associated infection. A further similarity between serum opsonic capacity and monocyte HLA-DR expression was that in the serially studied patients, two distinct patterns were found in those patients who died of infection and those who recovered from their infection. The mutual influence of these valuable predictors cannot be differentiated at this point. Assessment of the immune capability of the host must be taken into account, and reduced ability of patient serum to support phagocytosis is extremely predictive of fatal outcome. Furthermore, the ability to markedly increase opsonic capacity in the face of infection appears to demonstrate an intrinsic beneficial aspect of host defense against infection in these patients.

DISCUSSION

DR. EDWIN A. DEITCH (Shreveport, Louisiana): I would like to begin by congratulating Dr. Polk on an excellent presentation and also thanking him for getting the manuscript to me in time to sort through the data.

As we have seen, this presentation does deal with a complicated subject.

We know that the initial host defense against invading bacteria is, as Dr. Polk has said, the nonspecific host defense system. This is comprised primarily of the reticuloendothelial system, neutrophils, and humoral factors, such as complement. We also know that for neutrophils to function efficiently, the bacteria need to be buttered with humoral opsonins.

What Dr. Polk has shown us today is that after major injury, the opsonic capacity, or the ability of the serum of these patients to support the normal ingestion of bacteria, is reduced.

He has further shown that this reduction in opsonic activity is of predictive importance.

For a prognostic factor to be important, it needs to identify a patient at risk, but for a prognostic factor to be clinically important, it needs to have a causal relationship to something that can be altered.

The first question I have for Dr. Polk and his colleagues is: What is the relationship between the defect in opsonic activity and the development of infection?

The reason I ask this is that we have performed similar studies on burn patients. (Slide) If we collect serum from these burn patients within 24 hours of injury and measure C3, and plot its value against the magnitude of the injury, we find a nice inverse relationship, with patients having the biggest burns having also the biggest decrease in serum complement levels.

This decrease in C3 levels appears to be due to intravascular dilution or extravasation, since C3 activation products are not increased. Dr. Polk, is there any relationship between the magnitude of the injury (that is, injury severity score), and the level of opsonic activity of your patients upon admission?

Also, were there any relationships or differences between the injury severity scores of the three groups you identified: the patients who never became septic, those who became septic and did well, and those who died?

My laboratory has measured the opsonic activity of blister fluid in a neutrophil-mediated bactericidal assay. That is, we tested the ability of this fluid to support normal neutrophils in killing bacteria, and found that blister fluid would not support normal bactericidal activity, whereas when we added normal serum back to the blister fluid, bactericidal activity returned to normal.

We have done some repletion studies in which we added back either heated inactivated serum, which did not restore activity, purified IgG, which did not restore activity, or normal serum which did restore activity. So our working concept is that the decreased opsonic activity of blister fluid is due to a consumptive opsonopathy rather than to the presence of inhibitors. Although I think Dr. Polk's point that one may be diluting out the inhibitor is true, one may also be diluting out active components. Thus, an alternative explanation is that the serum does not have a defect, because there are adequate levels of complement components left, and only after further diluting out the serum is there a deficiency of factors that becomes apparent.

My second question, then, is: What is the mechanism for the decrease in opsonic activity? Have you done any studies that try to nail down whether this impaired opsonic activity is due to an inhibitor, or to determine whether this activity is due to a lack of normal factors?

My last question deals with the utility and possible interpretation of your findings. Do you believe that this defect is clinically important *in vivo,* since the cells circulate in 100% serum, not in 0.5% serum? Do you believe this defect is causally related to the development of infection, or do you believe that it is currently used primarily as a screening test to identify patients who are at increased risk of developing infections?

In conclusion, I would like to compliment Dr. Polk and his coworkers on a very interesting study, the beginning of a "story" for which I am sure more "chapters" will be written, and I hope that after this story has been told, we will have a better handle on why patients become immunosuppressed, and what we can do to reverse that immune suppression.

DR. ANDREW M. MUNSTER (Baltimore, Maryland): It is always a privilege to hear one of Dr. Polk's papers, and this one is as scintillating as his previous ones have been on the subject.

I have three questions. One relates to Dr. Deitch's earlier discussion. Some of the opsonic factors in serum are well known—IGG, for example—and these would be relatively easy to measure. Did he, in fact, initially measured some of these fairly simple things?

I am very intrigued by the fact that *Staphylococcus aereus* was the only test organism, and yet "septic patients" following trauma die mostly of gram negative sepsis, and the mechanism of opsonization is actually quite different, or *may be* different, for the two types of organisms.

So my second question is: What were the causative organisms of sepsis and death in this group of patients?

And my final question is perhaps a little puckish. We know that Dr. Polk has been playing with immune restorers, MDP being one. Have you tried to mix a little MDP into the pot and see if that improves the fate of the neutrophils?

DR. WILLIAM G. CHEADLE (Closing Discussion): I will respond first to Dr. Deitch. The clinical outcome groups were comparative with regard to injury severity score (ISS). In other words, there was no significant difference in the ISS of the good, the septic, and the dead groups. However, if one corrects the ISS for age, which gives the %D50, the dead group does have a significantly greater %LD50 score than the two groups of surviving patients, and this means the dead group constitutes an older age group.

We have not attempted to correct the defect in opsonization found in these patients by adding either normal serum, fresh frozen plasma, or other opsonic components. We have begun to attempt restoration of HLA-DR expression on monocytes, however, and if one adds compounds such as MDP, lipopolysaccharide, or interferon-gamma, these will produce an increase of depressed DR expression back to normal.

We have run the phagocytic assay at several different dilutions, all well below serum concentration, because actual differences become detectable at these dilutions. It may well be that dilution of certain inhibitors of opsonization is necessary for bringing out these changes. I think the assay has great potential, not only as a screening test to identify those patients at high risk of infection and death, but also in the evaluation of immune adjuvants in experimental models of infection.

Dr. Munster, we have measured serum IgA, IgG, and IgM serially, in these patients, and there is an initial reduction of serum IgG and IgM, with the exception of IgM in burn patients. This reduction of serum immunoglobulins may be partially responsible for the low values of certain groups in both the complement dependent and independent phagocytic assays, but does not explain the near-normal values seen in the heat inactivated assays of the surviving groups. We used the Collin's strain of Staph aureus, which is rare and to which there should not be preformed antibodies that would artifically increase serum opsonic capacity in the assay.

The scope of this particular research has been to identify in the severely injured patients immune parameters that, when measured early in the hospital course before the onset of sepsis, correlate with infection and death. In addition to age and degree of contamination, monocyte HLA-DR expression and serum opsonic capacity both correlate highly with clinical outcome. Correction of these defects with immunomodulators may prove beneficial to clinical outcome.

The Role of Feces, Necrotic Tissue, and Various Blocking Agents in the Prevention of Adhesions

J. PATRICK O'LEARY, M.D., GUNNAR WICKBOM, M.D., SOON-OK CHA, M.D., and ANNA WICKBOM

From the Department of Surgery, Baylor University Medical Center, Dallas, Texas

Ischemic tissue and intraperitoneal bacteria have been ascribed an etiologic role in the production of intra-abdominal adhesions. To further elucidate the role of these stimuli and to evaluate the potential protective effect of various agents, peritonitis was induced in 160 Sprague-Dawley rats. The experiment was stratified into those animals with peritonitis plus necrotic tissue, solid feces, both, or neither. The agents tested were a nonsteroidal anti-inflammatory (ibuprofen), free radical scavenger (SOD), and an anticoagulant (heparin). Death was less likely to occur in animals treated with heparin (3 of 40 *vs.* 12 of 40, $p < 0.01$) or SOD (4 of 40 *vs.* 12 of 40, $p < 0.05$). Ibuprofen did not increase survival in this model. Heparin protected against adhesions in animals with an ischemic ileum of limb and without solid feces. In animals with a nonischemic isolated segment of ileum and solid feces, adhesion formation was increased in both the ibuprofen and the heparin treatment groups ($p < 0.05$).

SINCE THE EARLIEST TIMES surgeons have been aware that celiotomy has been associated with the production of adhesions. Although the etiology of this exhuberant internal overhealing has remained unclear, a diverse list of treatments has been proposed to decrease the incidence of adhesion formation. These include but are not limited to chyme, fish bladder, carp or ox peritoneum, liquid parafin, olive oil, epinephrine solution, amniotic fluid, amniotic membrane, steroids, nonsteroidal anti-inflammatories, dextran, anticoagulants, saline, povidone iodine, and silicone.

The hypotheses upon which the proposed potential benefits of these different agents were based was often armchair surgical logic.

The importance of abdominal adhesions is obvious to all modern surgeons. Because celiotomy has become commonplace, the most common cause of bowel obstruction has changed from that secondary to hernia, to that secondary to abdominal adhesions.

When the peritoneum has been challenged by a noxious stimulus either in the form of a chemical irritant or a bacterial contamination, it responds with an outpouring of a fibrinogen-rich material that spreads throughout the abdominal cavity. Classic surgical wisdom has proposed that this response can localize infection or speed the body's host defense mechanisms to meet the challenge. Previous studies suggest that this may not be correct.[1-4] In a rodent peritonitis model, minidose heparin has been shown to decrease the incidence of adhesion formation, increase survival, and increase the rate of intra-abdominal fibrinogen clearance.[5]

Ischemia, a bacterial challenge, and the inflammatory response have all been incriminated in the development of adhesions. The present study was undertaken to elucidate the importance of each of these factors on the production of abdominal adhesions and on survival. In addition, various blocking agents have been selected that have a known effect on each of these processes. The effect of each of these blockers are evaluated in a rodent peritonitis model.

Materials and Methods

Peritonitis was induced in 160 male Sprague-Dawley rats weighing 250–300 g. Each rat was fasted for 24 hours and then sedated with ether and anesthesized with pentobarbital sodium given intraperitoneally (dose varying from 7.5 to 10.0 mg). The abdomen was shaved and then prepped with Povidone iodine and sterilily draped. A short midline incision was made and the cecum and terminal ileum were mobilized onto the ab-

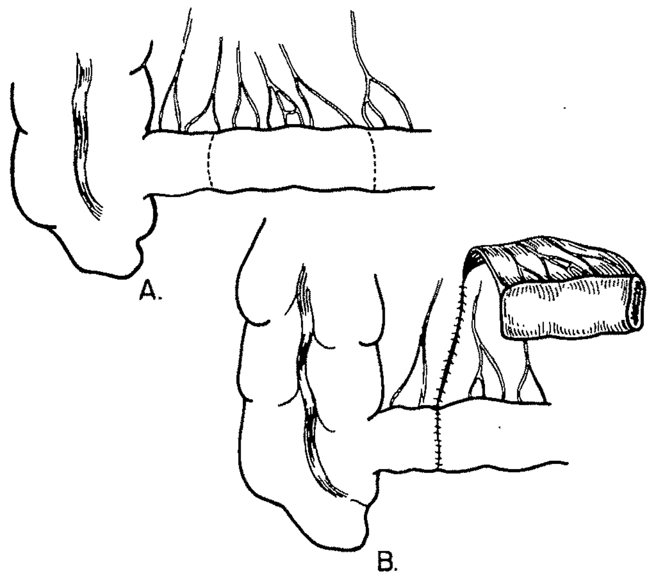

FIGS. 1A and B. The experimental model by which peritonitis was produced.

dominal wall. A 2-cm segment of ileum, 6 cm from the ileocecal junction was isolated on its vascular pedicle (Fig. 1). The intestine was divided at each end of this segment, and intestinal continuity was reestablished by anastomosing the ileum in an end-to-end fashion with 5-0 Vicryl suture. At this point the first variation in the model occurred. In one group, the isolated intestinal segment was left filled with feces, and in the second group, the feces was mechanically removed and the lumen of the segment rinsed with saline. Each group was then divided into two subgroups. In the first subset, the blood supply to the isolated ileum was left intact, and in the second subset, ligation of the vascular pedicle was accomplished with a single 3-0 silk tie. The incision was closed with two layers of absorbable suture. Therefore, the peritonitis challenge consisted of either necrotic intestine (N) plus feces (F) (subset PFN), necrotic intestine without feces (subset PN), viable isolated intestine plus feces (subset PF), or viable isolated intestine without feces (subset P) (Fig. 2). There were 40 animals in each of these divisions. Each division was then divided into four subsets of ten animals each. In each of these divisions, ten animals served as control; ten animals received 15 IU of heparin (H) subcutaneously 1 hour preoperatively and then one injection daily for the subsequent 3 days; ten animals received 3 mg of ibuprofen (IB) intramuscularly 1 hour preoperatively and then intramuscular injections twice daily for the subsequent 3 days; and ten animals received 1800 IU of superoxide dismutase (SOD) intraperitoneally one hour preoperatively and then intraperitoneally once daily for the subsequent 3 days. All animals that died were autopsied, and surviving animals were killed on postoperative day 14. Adhesions were graded by a team of observers on a scale of from Grade 0 (absent) to Grade 3 (matted abdominal contents). A small localized collection of adhesions around the isolated segment of ileum were considered as Grade 1. Mild diffuse involvement with an occasional adhesive band to the abdominal wall was considered Grade 2. Interobserver gradings were extremely constant using this previously established scoring method.

Statistical comparisons were accomplished using the Student's t-test for comparing like groups or chi square analysis for comparison of means of groups.

Results

The survival results are listed in Figure 3. When compared to control, animals treated with H or SOD had a greater chance for survival ($p < 0.01$; $p < 0.05$). Animals

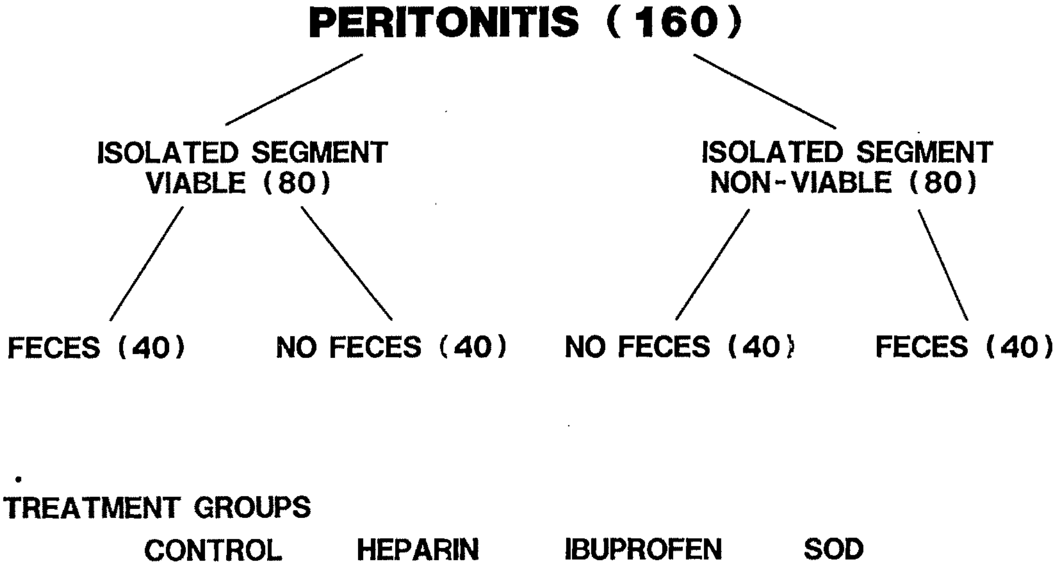

FIG. 2. Flow sheet for the development of the model. In the treatment groups, ten animals acted as control while ten animals were treated with each of the agents listed.

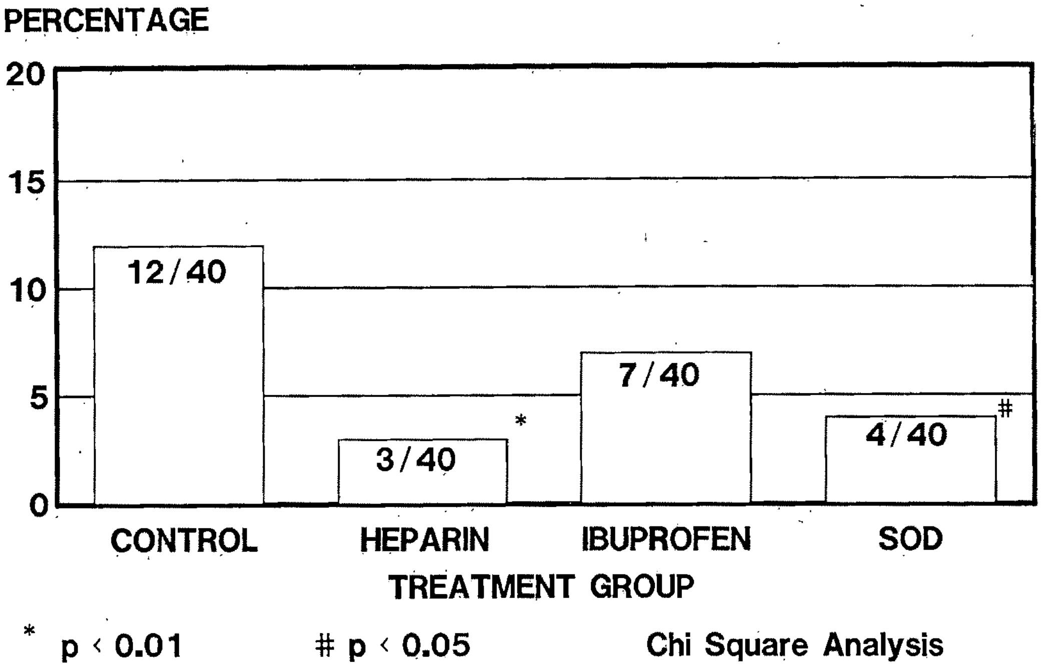

FIG. 3. The death rate for animals by treatment group.

treated with IB did not differ from control. There were no deaths in either the control or treatment groups in animals with peritonitis and a viable ileal segment and no solid feces. The only animals that died in the H treatment groups had a viable ileal loop and solid feces.

When the nontreatment (control) groups were compared, no statistical differences were seen in adhesion formation.

In the animals that had peritonitis alone with a viable segment of ileum and no feces (P) there were no differences in adhesion production between the treatment groups and the control group (Table 1).

In the animals with peritonitis and solid feces but no ligature (PF), there were significantly more adhesions in those treated with IB or H than the control group ($p < 0.05$) (Table 2). The SOD group did not differ from the control group.

In the animals with peritonitis and ligation of the pedicle of the excluded ileum but no solid feces (PN), there was a significant decrease in the amount of adhesions in the animals receiving H ($p < 0.001$) (Table 3). The IB group and SOD group did not differ from the control group.

In the animals with peritonitis, solid feces, and ligation of the pedicle for the ileum (PFN), none of the treatment modalities were effective in decreasing adhesions (Table 4).

Discussion

When the basic premises as to the cause of adhesions were analyzed and challenged experimentally, it became apparent that the causative agents were not as clearly related as previously suggested. The peritoneum's response to a hostile milieu, although multifactorial, seems to descend through a common pathway. For many years surgeons assumed that adhesions were the fibrous scarring that resulted from removing or damaging the peritoneum. Other situations that were thought to predispose to the production of adhesions included rough handling of tissue, evidence of foreign body (talc), active inhibition of fibrinolysis, damage to the peritoneal epithelial lining, healing associated with the exuberant ingrowth of fibroblasts, and the presence of an absorbable foreign body that produced an intense inflammatory response (cat gut and chromic suture).

Von Dembowsky demonstrated in 1888 that defects produced by abrasion or excision in animals were not associated with adhesion formation.[6] These observations were confirmed by Franz in 1902.[7] Similar results were shown by Babcock[8] and Robbins et al.[9] in humans

undergoing pelvic surgery. Despite these publications, resection of the peritoneum continued to be thought of as one of the most important factors in the production of adhesions. It was not until the publication of Ellis in 1962 that doubt was cast on this hypothesis.[10] He demonstrated that the most potent stimulus to the production of adhesions was tissue ischemia. Because tissue ischemia is often associated with peritoneal resection, it would not be surprising that some confusion might have existed as to the most important causative factor.

Although peritoneal healing has often been compared to cutaneous wound healing, recent studies have shown substantial differences. Ellis et al.[11] demonstrated that the area of peritoneal wound becomes covered by a fibrinous exudate. This event precedes an infiltration of monocytes, histiocytes, and polymorphonucleocytes. By the third day, many of these cells have disappeared and the surface becomes covered by a continuous layer of cells. At this point, fibroblasts invade the surface, and by the fifth day, the superficial layer is made up of flattened cells that closely resemble the adjacent peritoneum. By the second week, the area of injury is covered by a thin layer of fibrous tissue and a smooth mesothelium indistinguishable from the original surface. It is clear from the work of Ellis et al.[11] that the ingrowth of cells does not occur from the periphery of the wound but probably by seeding from the peritoneal cavity.

When the peritoneum has been injured by a bacterial agent or by mechanical methods, areas of ischemia are produced. Necrotic tissues excite an outflowing of fibrinogen from the peritoneal surface. Because the surface area of the peritoneum is roughly similar to the cutaneous surface, a large amount of fibrin can be deposited in a short period of time. The progression of the process is dependent upon the delicate balance between the outpouring of fibrinogen and the plasminogen-mediated resorption process. Many of the drugs that have been proposed to ameliorate the production of adhesions impact on this equation.

Filmy adhesions are the early result of the fibrin deposition. Dense adhesions are the result of the ingrowth of mononuclear cells that deposit collagen within the fibrin matrix. The dense adhesions play a role in the revascularization of ischemic tissue. Anti-inflammatory agents such as adrenocorticotrophic stimulating hormones, corticosteroids, or cytotoxic agents have been administered in an attempt to reduce this phase of adhesion maturation. Although some authors have shown these to be effective,[12,13] they have substantial side effects.

Nonsteroidal anti-inflammatory agents have been evaluated and found to produce similar effects without the compromising host immunity. Of these agents, the most widely tested has been ibuprofen. Siegler et al.[14] demonstrated a significant reduction in adhesion formation in the rabbit uterine horn when treatment groups were compared to control. There was no significant difference between those animals treated with dexamethasone or with ibuprofen. In subsequent studies using a similar model, Bateman et al.[15,16] demonstrated that adhesions secondary to either trauma or ischemia could be significantly reduced by treatment with ibuprofen. Nishimura et al.[17] further delineated these observations by demonstrating that in a model utilizing standardized abrasion, ischemia, or crush injury to the rabbit uterine horn, ibuprofen in a dose of 70 mg/kg immediately and 6 hours postoperatively decreased the incidence of adhesion formation. In subsequent studies they showed that a relationship existed between the dose of ibuprofen and the degree of adhesion formation.[18,19] These studies also demonstrated that the timing of therapy was important. Animals that received a high dose of ibuprofen within 8 hours of the operation did better than those that received the same dose more than 12 hours after operation.

The mechanism of ibuprofen's action is unknown. There is evidence that the nonsteroidals block the prostacyclin cyclooxygenase system that converts arachidonic acid to the prostaglandin endoperoxides. Whether this has its effect by decreasing the leukotaxic effect of the stable thromboxanes or if it has its effect on the chemotaxic lipoxygenase has not been elucidated. Other hypotheses have been proposed, but confirmatory evidence as to the mechanism of action is still lacking.

Not all studies with nonsteroidal anti-inflammatories have documented a reduction in adhesion formation. O'Brien et al.[20] could not show an effect on adhesion formation, although a marked reduction in the histologic markers of post surgical peritoneal injury was demonstrated.

In this study, adhesions were not prevented by ibuprofen. In fact, adhesions were greater and survival less when viable intestine was left in association with fecal contamination. The lack of demonstration of a protective effect may be related to the size of the dose of ibuprofen administered. In previous studies by Nishimura, the smallest dose to be associated with suppression of adhesion production was 35 mg/kg/d. If the results are to be compared with human dosage, the amount of drug is massive. In this study, a different model was used, active infection was present, the entire peritoneum was evaluated, animals were male instead of female, and only 24 mg/kg/d of ibuprofen was administered. This dose is lower than that given by Nishimura, but more closely resembles a normal dose for humans. Any of these variables might have affected the outcome.

Because it has been shown that ischemia may be the single greatest cause of adhesion formation, this facet was explored in greater detail. Recent evidence suggests that oxygen-derived free radicals are abundantly produced in a ischemic tissue.[21] This production far exceeds the amount of free radicals produced during aerobic metabolism. In normal circumstances these radicals are neutralized by intracellular products known as scavengers.[22]

A free radical is a molecule containing an odd number of electrons rendering it extremely chemically reactive. If a radical interacts with a nonradical, yet another free radical is produced. This allows free radicals to participate in extensive chain reactions.[23]

When a tissue becomes ischemic, cellular metabolism switches from the aerobic to the anaerobic state. With reperfusion, there is a marked increase in the number of free radicals produced and a concomitant increase in tissue permeability. This increase in permeability may well be the cause of the outflowing of fibrinogen when the peritoneum is rendered anoxic.

The scavengers that normally occur in the body are in an intracellular position. Despite this, Granger et al.[24] demonstrated that in feline intestinal ischemia, the intravenous (I.V.) administration of superoxide dismutase can almost completely prevent the expected increase in capillary permeability.

In this study, 1800 IU of superoxide dismutase was administered 1 hour preoperatively and then once daily for 3 days. This regimen decreased the incidence of death in the treatment group but had little effect in the production of adhesions. From these observations, it can be deduced that either superoxide dismutase does not play a role in the production of adhesions, or that the timing of the administration of the agent may have been inappropriate. It is entirely possible that the agent may have been substantially cleared by the peritoneal cavity prior to the time of the insult. Because the next dose appears 24 hours later, the golden time for impact on adhesion production may have already passed. The fact that the death rate was significantly decreased suggests that superoxide dismutase does impact on the injury produced by peritoneal sepsis in the model tested.

Peritonitis was associated with an increase in the amount of peritoneal adhesions. In the control groups (no treatment), the addition of feces or necrotic tissue did not seem to increase the absolute number of adhesions when compared to peritonitis alone. It was interesting that the death rate was considerably higher in those animals with solid fecal contamination. The rate was unaffected by the presence or absence of a ligature on the pedicle of ileum. This may be related to the size of the bacterial inoculum, which in turn is related to time and rate of clearance of the bacteria.

It was surprising that the adhesions increased in number in the animals that had a viable segment of intestine. The effect of this on the death rate is unclear from the experiment. It was also interesting to note that heparin decreased the death rate in all groups except those animals with viable intestine and feces. This beneficial effect may have been related to an increased rate of clearance of fibrin and therefore an increased rate of clearance of bacteria. The only three deaths that occurred in the heparin-treated animals occurred in those with viable intestine and solid feces. The deaths occurred early and may have been related to factors other than sepsis.

Acknowledgment

We would like to acknowledge the contributions of Gregory B. Buckley, M.D. for his advice and the gift of the superoxide dismutase used in this study.

DISCUSSION

DR. MARK A. MALANGONI (Louisville, Kentucky): I would first like to thank Dr. O'Leary for a very good presentation and also for providing me with a copy of his manuscript. I recommend his manuscript as an excellent review of the mechanisms that are involved in the pathogenesis of adhesions. In his manuscript, Dr. O'Leary emphasized that there are actually three components of the peritoneal adhesion response, and these relate either to inflammatory response to the bacteria themselves or to tissue ischemia.

His results show some points that I am going to ask some questions about, but first I would like to give some background on what he has discussed today.

First, when there is no treatment given, there is similar adhesion formation and adhesion response in all groups. When bacteria alone are provided—that is, when there are no feces in a nonnecrotic segment of ileum, regardless of treatment—there is also a similar response to adhesions. This would lead us to conclude that bacteria seem to be the principal effectors of the adhesion response, at least in this particular model.

When feces are added (and remember that feces tend to inhibit the clearance of bacteria), we see an increased mortality and no benefit from heparin on either survival or the adhesion response. When nonviable tissue as well as feces is present, nothing works very well, and in the absence of any type of antibiotic treatment or washing out of these bacteria, this is what we would expect.

I would like to ask some questions to help us determine the utility and applicability of this study to the clinical situation.

First, what kind of diet did these animals have? In general, rats are given a diet that is high in fiber, and this diet tends to give them a bacterial content in the large intestine and in the terminal ileum that is rather low in anaerobic bacteria. On the contrary, when a meat-fed diet is used, the anaerobic content is much higher, and this may, in fact, influence some of the results that Dr. O'Leary obtained.

Also, did you do any cultures to define the inoculum either by the species of bacteria involved or the numbers of organisms? This information would be useful to help us compare this model with other models of peritonitis, both monomicrobial and polymicrobial, and would help determine its utility.

Second, based on your results, do you believe there is any clinical role for heparin in patients, since in the presence of feces heparin alone did not decrease mortality?

And last, how do you propose that superoxide dismutase works in this model, particularly because this is not a model of ischemic with reperfusion, which has been the most common model investigated in the past for looking at the principal effects of superoxide dismutase.

DR. FRANCIS C. NANCE (Livingston, New Jersey): Dr. O'Leary was kind enough to share his manuscript with me, and I recommend it to you for reading because it is an elegantly designed study and a nice review of the various types of experimental models that have been used in trying to attack this problem of adhesions.

However, I come away from this paper with some frustration because after reading the paper or listening to the presentation, I don't feel myself any closer to having an answer to the adhesions problem.

Dr. O'Leary has used heparin, ibuprofen, and SOD for prevention of adhesions. I am not sure that, on the basis of the data, almost any other method is not better than his.

His results are somewhat confusing to me. Heparin increased adhesions in one of his groups, and decreased them markedly in the other. Heparin seems to be the most promising of the agents he studied, and I would like to ask him to try to elaborate on how heparin is working in this case, and whether he thinks that in this adhesion model, there is any future in heparin.

DR. J. P. O'LEARY (Closing discussion): Let me discuss Carter's criticism first. I have trouble and do not understand, Dr. Carter, exactly why the animals with heparin onboard and solid feces and nonviable bowel—which is the group that had increased adhesions—did less well. All the animals died and were autopsied either at the time of death or the time of being killed. I think what happened was that when some of the animals died, we had the chance to examine their peritoneal cavity early and therefore saw the early type of fibrinous adhesions that one will often see. That is probably why the adhesion score was higher.

Now, why they died is still not clear to me. I would like to believe that maybe they were bleeding as a result of the amount of heparin that we used (although we used the same dose of heparin throughout), but I do not have an explanation for this.

The diet that the rats received, Dr. Malangoni, was a regular chow diet. We did do cultures. We did not include those cultures in the report because it was such a mixed bag of cultures.

You are correct in deducing that we discovered less aerobes than one might have anticipated, and I believe that this is because we were using the rat-chow diet.

Do I think there is a clinical role for heparin? I think it is too premature to say that; but then I look across our operating rooms and see vascular surgeons who mistreat the small intestine in the worse conceivable way while they perform aneurysectomies. Yet those patients don't seem to return with the incident of bowel obstruction that my simple colectomies or resection of small bowel seem to cause patients to return with. Therefore, there may be a clinical role for the use of heparin, but at this particular point, based on the data in the literature that I know of, I could not make that proposal.

With regard to SOD, superoxide dismutase: it is not clear to me how this scavenger works, since it would have to be intracellular to clear the radicals, and yet we are administering it extracellularly. Earlier data from members of our own organization have shown that this is, in fact, effective, and it is effective through intravenous administration. Yet I am not sure of its site of action.

Only one H_2 antagonist controls pH for up to 12 hours on a single dose

PEPCID® I.V. (Famotidine, MSD) is indicated in some hospitalized patients with pathological hypersecretory conditions or intractable ulcers or as an alternative to the oral dosage forms for short-term use in patients who are unable to take oral medication.

The recommended dosage is 20 mg q12h. Dosing intervals may need to be prolonged or dosage reduced in patients with severe renal insufficiency (creatinine clearance <10 mL/min) to adjust for the longer elimination half-life of famotidine. PEPCID I.V. is contraindicated in patients who are hypersensitive to any component of this medication. The adverse reactions reported for PEPCID Tablets may also occur with PEPCID I.V. In addition, transient irritation at the injection site has been observed with PEPCID I.V.

TABLETS
Pepcid®
(Famotidine/MSD)
20 mg and 40 mg

ORAL SUSPENSION
Pepcid®
(Famotidine for Oral Suspension/MSD)
40 mg per 5 mL

INJECTION
Pepcid® IV
(Famotidine/MSD)
20 mg per 2 mL

Contraindications: Hypersensitivity to any component.

Precautions: ***General:*** Symptomatic response to therapy does not preclude the presence of gastric malignancy.

Patients with Severe Renal Insufficiency: Longer intervals between doses or lower doses may be needed in patients with severe renal insufficiency (creatinine clearance <10 mL/min) to adjust for the longer elimination half-life of famotidine (see Clinical Pharmacology and Dosage and Administration sections of Prescribing Information).

Information for Patients: The oral suspension should be shaken vigorously for 5-10 seconds prior to each use, and unused constituted oral suspension should be discarded after 30 days.

Drug Interactions: No drug interactions have been identified. Compounds tested in man include warfarin, theophylline, phenytoin, diazepam, aminopyrine, and antipyrine.

Carcinogenesis, Mutagenesis, Impairment of Fertility: In rats and mice given oral doses up to approximately 2500 times the recommended human dose for active duodenal ulcer, there was no evidence of carcinogenic potential, no evidence of a mutagenic effect, and fertility and reproductive performance were not affected.

Pregnancy: *Pregnancy Category B*—There are no adequate or well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Nursing Mothers: It is not known whether famotidine is secreted into human milk; however, it is secreted into the milk of lactating rats. A decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children have not been established.

Use in Elderly Patients: No dosage adjustment is required based on age but may be necessary in severe renal impairment (see Clinical Pharmacology section of Prescribing Information).

Adverse Reactions: The adverse reactions listed below have been reported during domestic and international clinical trials in approximately 2500 patients. In the placebo-controlled clinical trials, the incidence of adverse experiences with PEPCID Tablets, 40 mg at bedtime, was similar to that with placebo.

Incidence Greater than 1%: The following adverse reactions have been reported to occur in more than 1% of patients on therapy with PEPCID in controlled clinical trials and may be causally related to the drug: headache (4.7%), dizziness (1.3%), constipation (1.2%), and diarrhea (1.7%).

Causal Relationship Unknown: The following other adverse reactions have been reported in clinical trials. While a causal relationship could not be established for these infrequently reported events, causality cannot be excluded. *Body as a Whole*—Fever, asthenia, fatigue. *Cardiovascular*—Palpitations. *Gastrointestinal*—Nausea, vomiting, abdominal discomfort, anorexia, dry mouth, liver enzyme abnormalities. *Hematologic*—Thrombocytopenia. *Hypersensitivity*—Orbital edema, conjunctival injection. *Musculoskeletal*—Musculoskeletal pain, arthralgia. *Nervous System/Psychiatric*—Paresthesias; grand mal seizures (single report); psychic disturbances including depression, anxiety, decreased libido, hallucinations (single report); insomnia; somnolence. *Respiratory*—Bronchospasm. *Skin*—Alopecia, acne, pruritus, rash, dry skin, flushing. *Special Senses*—Tinnitus, taste disorder.

The adverse reactions reported for PEPCID Tablets may also occur with PEPCID Oral Suspension or PEPCID I.V.; in addition, transient irritation at the injection site has been observed with PEPCID I.V.

Management of Overdosage: There is no experience to date with deliberate overdosage. Up to 640 mg/day have been given to patients with pathological hypersecretory conditions with no serious adverse effects. In the event of overdosage, treatment should be symptomatic and supportive. Unabsorbed material should be removed from the gastrointestinal tract, the patient should be monitored, and supportive therapy should be employed.

Dosage and Administration: ***Duodenal Ulcer:*** The recommended adult oral dosage for active duodenal ulcer is 40 mg h.s.; most patients heal within 4 weeks, and it is rarely necessary to use the full dosage for longer than 6 to 8 weeks. A regimen of 20 mg b.i.d. is also effective. For maintenance therapy, the recommended oral dosage is 20 mg h.s.

Pathological Hypersecretory Conditions (e.g., Zollinger-Ellison Syndrome, Multiple Endocrine Adenomas): The dosage varies with the individual patient; the recommended adult oral starting dosage is 20 mg q6h, but some patients may require a higher starting dosage. Dosages should be adjusted to individual patient needs and continued as long as clinically indicated; up to 160 mg q6h have been administered to some patients with severe Zollinger-Ellison syndrome.

Oral Suspension: The Oral Suspension may be substituted for Tablets for those patients who cannot swallow tablets.

Directions for Preparing PEPCID Oral Suspension: Prepare suspension at time of dispensing. Slowly add 46 mL Purified Water. Shake vigorously for 5-10 seconds immediately after adding the water and immediately before use.

Stability of PEPCID Oral Suspension: Unused constituted oral suspension should be discarded after 30 days.

Intravenous Administration: In some hospitalized patients with pathological hypersecretory conditions or intractable ulcers, or in patients who are unable to take oral medication, the recommended intravenous dosage is 20 mg q12h. For preparation of solutions for injection or infusion and for compatible diluents, please see Prescribing Information. Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit.

Concomitant Use of Antacids: Antacids may be given concomitantly if needed.

Dosage Adjustment for Patients with Severe Renal Insufficiency: In patients with severe renal insufficiency (creatinine clearance less than 10 mL/min), the elimination half-life of famotidine may exceed 20 hours, reaching approximately 24 hours in anuric patients. Although no relationship of adverse effects to high plasma levels has been established, to avoid excess accumulation of the drug, the dosage may be reduced to 20 mg h.s. or the dosing interval may be prolonged to 36 to 48 hours as indicated by the patient's clinical response.

How Supplied: Tablets, containing 20 mg or 40 mg famotidine, with hydroxypropyl cellulose, hydroxypropyl methylcellulose, iron oxides, magnesium stearate, microcrystalline cellulose, starch, talc, and titanium dioxide as inactive ingredients, in bottles of 30 and unit-dose packages of 100; Oral Suspension, containing per 5 mL after constitution with 46 mL Purified Water, 40 mg famotidine, with citric acid, flavors, microcrystalline cellulose and carboxymethylcellulose sodium, sucrose, and xanthan gum as inactive ingredients, and sodium benzoate 0.1%, sodium methylparaben 0.1%, and sodium propylparaben 0.02% added as preservatives, in bottles of 400 mg famotidine for constitution; Solution for intravenous injection, containing 10 mg famotidine per mL, with L-aspartic acid 4 mg, mannitol 20 mg, and water for injection q.s. 1 mL as inactive ingredients, and benzyl alcohol 0.9% added as preservative to the multidose vial, as 10x2-mL single-dose vials and as 4-mL vials.

Surgical Treatment of Acute Traumatic Tear of the Thoracic Aorta

WALTER H. MERRILL, M.D., ROBERT B. LEE, M.D., JOHN W. HAMMON, JR., M.D., WILLIAM H. FRIST, M.D., JAMES R. STEWART, M.D., and HARVEY W. BENDER, JR., M.D.

Acute traumatic tear of the thoracic aorta is a severe injury with a high mortality rate. This condition requires expeditious evaluation and prompt surgical intervention in order to improve patient survival. The experience at the authors' institution from 1971 to 1987 includes 41 patients who sustained acute traumatic tear of the thoracic aorta and reached the hospital alive. The purpose of the study was to evaluate the surgical management of this injury with regards to mortality rate and the incidence of spinal cord injury. Five patients died from exsanguination before definitive repair could be undertaken. Thirty-six patients had repair of traumatic aortic tear in the area of the isthmus. Nine patients were operated upon with the clamp and sew technique, 20 patients had a heparin-bonded shunt placed, and seven patients were treated by repair with cardiopulmonary bypass. There were five operative deaths that were not related to the technique employed. Two patients without preoperative evidence of spinal cord injury developed paraparesis. No patient had postoperative paraplegia. Despite rapid transport, expeditious evaluation, and emergency thoracotomy, some patients die from exsanguination prior to definitive repair. Even with the provision of distal aortic perfusion during clamping, the risk of spinal cord injury is not eliminated.

IN THE UNITED STATES there are approximately 100,000 deaths per year secondary to trauma; 25% of the deaths are the result of blunt injury to the chest. It is estimated that about one-third of the patients who suffer blunt chest trauma will have a traumatic tear of the thoracic aorta.[1] Greendyke[2] found that 16% of automobile accident fatalities were due to aortic rupture. Aortic injury is most frequently seen as a consequence of high speed deceleration, usually as a result of motor vehicle accidents. This injury has also been seen after falls from heights, airplane accidents, kicks by animals, and sudden burial by landslide.[3]

From the Department of Cardiac and Thoracic Surgery, Vanderbilt University School of Medicine, Nashville, Tennessee

It is well known that most patients who sustain an aortic tear die at the scene. However, in approximately 15–20% of patients free rupture and exsanguination are prevented by the aortic adventitia and surrounding mediastinal structures. These patients survive long enough to reach the hospital. Without definitive treatment most of those who reach the hospital alive die within one week.[4] Therefore, patients with acute aortic tear require rapid and thorough evaluation and expeditious treatment to maximize their chances for survival.

Since the initial success in repairing an acute tramatic aortic tear in 1959 by Karl P. Klassen,[5] there has been continued interest in the development of operative techniques to provide expedient repair while minimizing distal organ ischemia. Various methods have been used including no shunt (clamp and sew),[6-11] heparin-bonded shunts,[12-16] and various bypass techniques with systemic heparinization.[17-20] This report is limited to patients operated upon during the acute phase of their injury prior to healing of the aorta and development of a chronic aneurysm (<7 days). A retrospective analysis of this experience was undertaken to evaluate the type of injury incurred, the influence of time from injury to repair, and the incidence of spinal cord injury and mortality rate relative to the operative technique employed.

Materials and Methods

At the authors' institution between July 1971 and July 1987, 41 patients were seen after sustaining blunt chest injury and acute aortic tear in the area of the aortic isthmus. Thirty-three patients were male and eight were female. Age ranged from 10 to 79 years with a mean age of 33 ± 16.8 years. Of the 41 patients, 29 were less than

40 years of age. Forty patients suffered deceleration injuries. Thirty-seven were involved in automobile accidents, two in motorcycle accidents, and one in a go-cart accident. One patient was a pedestrian who was struck by a car.

Thirty-one patients arrived by ambulance, and ten arrived by helicopter. Only 12 patients were seen from 1971 to 1979, while 29 were seen between 1979 and 1987.

The history and physical examination provided valuable information but were by no means diagnostic. The symptom most often elicited was retrosternal chest pain (23 of 41 patients). Nineteen patients were hypotensive, with a systolic pressure less than 100 mmHg, on presentation in the emergency room. Pulse discrepancy and evidence of external chest trauma were frequently encountered physical findings, occurring in 17 and 16 patients, respectively (Table 1). Three patients had no femoral or leg pulses associated with arm hypertension. One patient had paraplegia on admission.

Thirty-five patients had roentgenographic findings suggestive of aortic injury, but six patients had a chest roentgenogram that was interpreted as normal. A widened mediastinum was seen in 35 patients. Fourteen patients had multiple rib fractures, and obscuration of the aortic knob was seen in ten patients. The most frequent radiographic findings are listed in Table 2.

The severe force that resulted in aortic tear caused significant associated injuries in all but two patients. Twenty-eight patients had major fractures, with femoral fractures being the most common. Sixteen patients experienced significant head trauma. Twelve patients required exploratory laparotomy; 10 of these were performed prior to thoracotomy in unstable patients with exsanguinating intraabdominal hemorrhage. Splenectomy was the procedure most often performed (Table 3).

TABLE 2. *Most Frequent Chest Roentgenogram Findings*

Wide mediastinum	35
Multiple rib fractures	14
Left pleural effusion	14
Blunt aortic knob	10
Normal chest roentgenogram	6

All patients were treated by emergency aortography, which was diagnostic in all instances except one. This patient's initial aortogram was thought to be within normal limits. Serial chest radiographs documented a widening mediastinum, prompting a second aortogram, which documented an aortic isthmus tear.

It has been the authors' policy to proceed with emergency thoracotomy and repair of the aortic tear once the diagnosis has been established. Thoracotomy is delayed only in patients with life-threatening intracranial injury or exsanguinating intra-abdominal hemorrhage. All patients except four were operated upon within 24 hours of injury. These patients were transferred from outside institutions at 2, 3, 4, and 7 days after their injury. Twenty-five patients were operated upon within 8 hours of their injury.

All patients had general anesthesia with a double-lumen endotracheal tube. Patients were monitored with a central venous pressure line, right radial arterial line, electrocardiogram, and Foley catheter. A standard posterolateral thoracotomy through the fourth or fifth intercostal space was performed with resection of a rib when necessary. Great care was taken to gain proximal and distal control prior to entering the mediastinal hematoma. Depending on the surgeon's preference and the patient's condition, a technique of no shunt, heparin-bonded shunt, or partial bypass was employed. A low porosity Dacron interposition graft was usually inserted. Two patients with limited noncircumferential tears were repaired primarily.

Results

Despite rapid transport and expeditious evaluation five patients did not survive to have their injury repaired. One patient with an aortic tear documented by arteriography in another hospital was transferred for definitive repair but died of exsanguinating hemorrhage immediately upon arrival in the emergency room. Two additional patients died in the arteriography suite from free rupture. Two patients had angiography but ruptured en route to the operating room. Emergency thoracotomy and control of bleeding was accomplished, but resuscitation was unsuccessful in both.

Thirty-six patients were treated by repair of traumatic tear of the thoracic aorta in the area of the isthmus (Table 4). The nine patients in the clamp and sew group had a mean cross-clamp time of 35.7 minutes. There was one death for a mortality rate of 11.1%. The mean cross-clamp time for the 20 patients in the shunt group was 44.3 minutes. Two patients died (mortality rate: 10%). The shunt was placed from the aortic arch to the descending thoracic aorta in 18 patients, and it was placed from the left ventricular apex to the aorta in two patients. The seven patients in the partial bypass group had a mean cross-clamp time of 39.4 minutes. There were two deaths in this group for a mortality rate of 28.6%.

Of the 36 patients treated by repair five died, resulting in an overall mortality rate of 13.9%. The one death in the clamp and sew group occurred in a patient who initially required urgent laparotomy for exsanguinating intra-abdominal hemorrhage. Following laparotomy an aortogram documented a tear in the aortic isthmus. The patient was returned to the operating room hypothermic, acidotic, and hypotensive. Ventricular fibrillation occurred when the aorta was cross-clamped. Repair and resuscitation were unsuccessful.

Both deaths in the shunt group occurred under similar circumstances. Each patient had extensive dissection of the aorta both proximally and distally making repair difficult and resulting in exsanguination in each case.

There were two deaths in the partial bypass group. Both patients exhibited loss of distal pulses, metabolic acidosis, and hypotension after operation. One patient with an associated myocardial contusion died of right ventricular rupture and exsanguination after cross-clamping the aorta. The other patient had preoperative pulmonary edema, left ventricular failure, hypotension, and acidosis. When the aortic cross-clamp was applied ventricular fibrillation occurred. Repair and resuscitation were unsuccessful.

One patient presenting with paraplegia died intraoperatively. There were no instances of postoperative paraplegia. Two patients with normal motor function of the lower extremities prior to operation had paraparesis after operation. Both patients were in the shunt group. One patient had a shunt from the left ventricle to the descending aorta. Cross-clamp time was 50 and 75 minutes, respectively, for these two patients. Each was ambulatory with assistance at discharge and doing well 1 year after repair.

TABLE 4. *Technique of Repair and Results*

Technique	Clamp Time (min) (mean)	N	Mortality Rate	Spinal Cord Injury
Clamp and sew	35.7	9	1 (11.1)	0
Shunt	44.3	20	2 (10.0)	2
Partial bypass	39.4	7	2 (28.6)	0

Values in parentheses are percentages.

There were no postoperative deaths in those patients who survived operation. Morbidity rate was related to concomitant injuries rather than to the aortic repair. There was no statistically significant difference in survival of those patients operated upon less than or greater than 8 hours from the time of injury.

Discussion

The clinical presentation is quite variable in patients with traumatic tear of the thoracic aorta. More than 90% of the patients are involved in automobile accidents.[9,10,20-22] Physical examination may be helpful, but it may be misleading. Some patients have no evidence of thoracic trauma, while others have multiple rib fractures, hemothoraces, or flail chest. The triad of findings mentioned by Symbas et al.[19] are: (1) difference in pulse amplitude between upper and lower extremities; (2) hypertension in the upper extremities; and (3) widening of the mediastinum on the chest roentgenogram. These are helpful in making the diagnosis, but these findings are not present uniformly.

The initial chest roentgenogram may be the only indication of aortic injury. As documented by virtually all series[9-11,20-23] as well as this series, widened mediastinum is the most common finding in patients with traumatic tear of the aorta. An abnormal contour of the aortic knob is also seen frequently. Although multiple rib fractures are frequently associated with aortic tear, it has been shown that acute traumatic tear of the thoracic aorta may occur in the absence of rib fractures.[24] It has also been shown that upper rib fractures alone are not associated with a high incidence of aortic rupture.[25]

There are many roentgenographic signs that various authors have suggested as possible clues to the presence of acute traumatic tear of the aorta.[26] However, it must be kept in mind that some patients with an aortic tear have a virtually normal chest roentgenogram.[21,27] In the present series six patients with a documented aortic tear had a chest roentgenogram that was initially interpreted as normal. It seems reasonable that even in the absence of roentgenographic signs suggesting an aortic tear, any patient with a history of a high speed deceleration accident should be strongly considered as a potential candidate for aortography.

Aortography remains the generally accepted standard test for the diagnosis of this injury. In this hospital of every 100 aortograms performed approximately 10–12% are positive. It has been suggested that of all patients who undergo aortography in an attempt to document the presence or absence of an acute traumatic tear of the thoracic aorta, approximately 10–20% of the patients will have a positive study.[28]

Recently there has been increased interest in computed tomography (CT) as a method for diagnosing acute tear of the thoracic aorta. CT signs of acute tear include increasing caliber of the aorta, internal displacement of intimal calcification, visualization of an intimal flap, or visualization of the false channel.[28] To date no prospective randomized trial has been published comparing CT to arteriography in regards to sensitivity and specificity of diagnosis of acute aortic tear.

It has been the authors' practice to undertake prompt evaluation and management of multisystem injuries in these patient who are often in critical condition. The majority of these patients were operated upon within 8 hours of their injury. Thoracotomy and repair of aortic tear is delayed only in those patients with life-threatening intracranial injury or exsanguinating intra-abdominal hemorrhage. The necessity of prompt intervention is clearly evident by the fact that five patients exsanguinated in the hospital before definitive repair could be undertaken.

There is a divergence of opinion as to the best operative technique for avoiding distal organ ischemia while minimizing mortality rate. Presently, there are three accepted techniques for managing traumatic tear of the thoracic aorta: clamp and repair, external heparin-bonded shunt, and partial or complete bypass. Many authors have stated that the simple clamp and sew technique is safe and does not result in an increased incidence of paraplegia when compared to other methods.[9–11,29,30] This technique may be considered when the aortic injury seems limited and the surgeon is reasonably certain that repair can be accomplished quickly, with a cross-clamp time less than 30 minutes. Katz et al.[31] documented that there is an incrementally increased risk of spinal cord injury when the cross-clamp time exceeds 30 minutes.

In recent years the use of an external heparin-bonded shunt has been preferred by the authors. It usually provides adequate decompression of the proximal aorta and adequate flow in the descending aorta without the necessity of systemic heparinization, which may be dangerous in certain patients with multisystem injuries. Two of these patients who were repaired with this method developed paraparesis. In both patients there were technical difficulties with the repair due to extensive dissection and aortic injury, and the clamp times were prolonged. This prolonged clamp time is the probable explanation of the development of the spinal cord injury. On the other hand, there could have been inadequate flow through the shunt. One of the patients was repaired with a left ventricular apex to aorta shunt. Marvasti et al.[14] found a higher incidence of spinal cord injury when the proximal cannulation site was the left ventricle. They attributed this to lower mean pressure in the left ventricle and possible occlusion of the shunt tip during systole. They also noted that the shunt could be malpositioned when placed in the left ventricle, thus decreasing flow through the shunt.

Bypass techniques were used more commonly in the authors' earlier experience. Most authors have now abandoned bypass techniques because of concerns regarding total body heparinization of multiple injury patients. One recent large series supports the use of extracorporeal circulation. Pate[20] reported 59 patients with acute aortic tear at the isthmus. Forty-seven of these patients had repair using a pump oxygenator. There were two deaths and one case of paraplegia. Neither of the deaths was due to exsanguination. However, one death was attributed to a head injury in a patient who had received heparin during bypass. In this excellent series there was a mortality rate of approximately 5%. Other series have reported a mortality rate of approximately 15–30% for patients undergoing repair of aortic tear on cardiopulmonary bypass.[11,22]

In the authors' experience, the mortality rate is not influenced by the technique of repair. Rather, mortality rate is related to the presence or absence of extensive dissection, which makes repair and hemostasis difficult, and to the preoperative condition of the patient. Those patients who reached the operating room in stable condition and who did not have extensive dissection all survived.

It has been suggested that several adjuncts might possibly improve spinal cord protection during clamping of the aorta. In the experimental laboratory systematic evaluation of the use of corticosteroids, mannitol, free radical scavengers, and thiopental was performed.[32,33] Only thiopental has been shown to provide a statistically significant reduction in the frequency of paraplegia. In recent years it has been the authors' practice to administer 20 mg/kg thiopental intravenously to patients with traumatic tear of the aorta prior to application of the aortic clamps.

Recently, a new technique for monitoring somatosensory cortical evoked potentials has been developed in the experimental laboratory and applied clinically. Lashinger et al.,[34] Coles et al.,[35] and Oka and Miyamato[36] have reported their experience with this technique. Their results seem promising, but because of the technical sophistication of the method, it has been difficult to duplicate results, and the method has not gained wide acceptance. The authors' efforts have concentrated on accurate, expeditious repair of the torn aorta in the expectation of minimizing cross-clamp time and blood loss. The repair is performed with meticulous attention to detail in order to achieve good hemostasis and avoid reclamping the aorta.

Acute traumatic tear of the thoracic aorta is a surgical emergency that requires a high index of suspicion, prompt diagnosis, and urgent operative intervention. Repair should be performed in an accurate, expeditious manner. Despite the use of techniques to limit distal organ ischemia, the risk of paraplegia is not eliminated.

DISCUSSION

DR. KENNETH MATTOX (Houston, Texas): I want to congratulate Dr. Bender and his coauthors for a well prepared and beautifully presented paper. Some of my comments relate to the manuscript, which was provided to me well in advance.

This is a retrospective review of three techniques, historically randomized by national evolutions in practice trends and by physician preference. Because of numerous changes in perioperative management, injuries repaired on cardiopulmonary bypass early in this series cannot really be compared with those repaired during this decade, and this is true of all series in the literature.

This paper supports the composite literature review demonstrating that none of the current acceptable techniques of protection should be either championed or condemned. Patients, families, and plaintiff lawyers should understand that no technique eliminates postrepair paralysis. Recent series, however, have demonstrated that the lowest mortality and paraplegia are actually in the clamp/repair group. Neither the Gott shunt nor the pump protects the patient from death or paralysis, and both actually make this complex operation much more difficult.

This manuscript, like many others, focuses on a frequently quoted 30-minute "optimal" clamp time. These statements may not only be fallacious, but also point to something unobtainable, forcing a hurried operation and inviting imprecision and litigation. The length of the cross clamp time is, in truth, a function of the extent and complexity of the injury, and not necessarily a reflection of the surgeon's technical prowess and dexterity. Virtually all series, including the one reported here, cite mean clamp times greater than 35 minutes, with a very wide standard deviation. Our own clamp times average 38 minutes. There are reported clamp times as long as 110 minutes, with documented distal aortic perfusion pressure at 20 mm of mercury without the appearance of paraplegia. Also, clamp times of less than 15 minutes may be associated with paraplegia.

Because of a false sense of security, when a shunt is used, clamp times tend to be longer than with clamp repair technique. This paper, like many others, states that if a surgeon anticipates a clamp time longer than 30-minutes a shunt should be considered in order to (1) protect the patient from paralysis, and (2) protect the surgeon from lawsuit. Unfortunately, both statements are not true.

Except in sophisticated research centers, in the case of acute traumatic aortic transsections, which is usually a nocturnal event, somatosensory-evoked potential measurement is difficult, cumbersome, misleading, and inconsistent. Until solid, new, conclusive data is presented, our publications should cease to cite its use, or else we all will be legally required to purchase and utilize this unproven and confusing monitoring technique.

This lesion is one of the most litigious in vascular surgery. Twenty-five per cent of patients with this injury and paraplegia are now filing lawsuits. These suits are frequently supported by sanctimoniously rigid statements—some made even by members of this Association. Numerous unfounded, emotionally polarized but published statements concerning protection, clamp times, and monitoring are loudly quoted in court, with millions of dollars in settlements and judgments.

Carefully hidden in the many papers on this injury are notations on complications from the shunt itself: displacement, inadequate flow, postoperative bleeding, aneurysms, and many others. One question: Did you have any shunt-related problems that were found in your shunt patients?

I congratulate Dr. Bender and his coauthors for reaffirming the lethality and complexity of this injury, and for documenting the safety and utility of all acceptable current techniques.

DR. JAMES D. HARDY (Jackson, Mississippi): I congratulate Dr. Bender on his excellent presentation of his impressive results. Our experience at the Hospital of the University of Mississippi has been very similar to his.

When I received the program, I called Vanderbilt to ask whether or not their group planned to show a movie. They did not.

May I have the movie, please. (A movie was shown).

This young man had been in an automobile accident and sustained a fracture of the femur and a head injury. The widened mediastinum exhibited on chest x-ray prompted an aortogram, and as you can see, there were two tears in the aorta: one at the most common site, just distal to the left subclavian artery, and another about 10 cm above the diaphragm. Over the years, we have seen traumatic aneurysms at various sites, extending from the aortic valve to the diaphragm.

Here the movie shows the subpleural hematoma in the mediastinum and, after incising the parietal pleura, an aortic clamp's being applied just adjacent to the left subclavian artery and a second clamp below the apparent level of the aortic injury. Note the preservation of the vagus, recurrent, and phrenic nerves. Now the hematoma has been evacuated and some blood is leaking through the aortic adventitia, the only layer of the aortic wall still intact. The intima and the media, still one unit, were divided completely by the deceleration accident, and the ends of the aorta (except for the adventitia), have retracted from each other about 5 cm. With a complete tear such as this, we do not attempt a primary repair; we insert a fabric graft, here Dacron™, to restore aortic continuity. Incidentally, if needed, Teflon felt backing can be very effective in achieving secure hemostasis at each end of the fabric graft.

Now we have removed the aortic clamps, and you can see that the suture line hemostasis is satisfactory.

(Please stop the film.)

The lateral tear just above the diaphragm was then readily closed, using Teflon felt backing of the sutures.

Again, our data for the management of traumatic aortic aneurysms at the level of the isthmus are very similar to those presented by Dr. Bender and his colleagues. I was gratified to find that, although six different staff surgeons performed or supervised the operations, since 1970, our results have been almost uniformly satisfactory when the lesion was at the level of the isthmus, when the patient was in stable condition at the time of thoracotomy and when the patient had no other major injury, such as head or liver trauma.

Lastly, I personally heparinize the patient while the clamps are on the aorta. I have used aortic bypass less and less in recent years.

I have enjoyed this paper very much.

DR. FREDERICK GROVER (San Antonio, Texas): I would like to compliment Dr. Bender and his co-authors on a fine study of a difficult problem.

During our 15 years together in San Antonio, Kent Trinkle and I have had a similar number of patients with this injury.

We would agree that a high index of suspicion and a prompt diagnosis are imperative, and angiography should be performed very early in patients suspected of this injury. This has been helpful in our experience, both for diagnosing the lesion and for exclusion of patients with a wide mediastinum who, indeed, do not have the injury. In addition, it identifies the location of the injury. We have also seen avulsion of the innominate artery from the ascending aorta, which, of course, requires a completely different incision.

Some people are now advocating the use of CT scanning, and I wonder how the Nashville group feels about this.

Our current policy in regard to operative technique is to place a tubular graft in all patients with complete transection of the aorta, but sometimes to perform a primary repair in those patients with a partial transection. We went through a phase when we were trying to do primary repairs in all patients and had some technical problems with tearing and bleeding when trying to pull the ends of a completely transected aorta together without a graft. In the past, we have also attempted to use intraluminal prostheses in these patients, thinking that it might shorten our cross-clamp time, but have been disappointed because most of them have had too small an aorta to use these grafts, and too short of a proximal portion of the aorta distal to the subclavian before the location of the transection. I would be interested if you have used any of these intraluminal grafts, and would like to learn about your technique regarding insertion of the graft.

The incidence of paraplegia is of concern to all of us. We have had patients with paraplegia in spite of having been on partial bypass and having had an expeditious operation. Therefore, we began using the "clamp and sew technique," as popularized by the Baylor group; yet in the past year, we have had two patients with a paraparesis in whom we used this technique, despite there being only 30 minutes of cross-clamp time.

There is one question I would like to ask in regard to this. In an attempt to control proximal hypertension we give intravenous nitroprusside when we use the "clamp and sew" method, but when we monitor the dorsalis pedis pressure distally, we sometimes find that the distal pressure is alarmingly low. Do you monitor the distal pressure, and do you use nitroprusside? How do you counteract the presumed decrease in collateral flow when treating these patients with intravenous nitroprusside?

Because of these recent incidences of paraparesis, we are currently considering using the Biomedicus pump with left atrial to femoral artery bypass. Have you had any experience with this?

My final question concerns the prioritizing of injuries. You alluded to the fact that in somebody who was bleeding heavily from the abdomen, you would explore the abdomen first. How do you prioritize these injuries? What about the patient who has a dilated pupil and a neurologic injury?

Again, I enjoyed your paper very much on this difficult management problem.

DR. GEORGE C. KAISER (St. Louis, Missouri): Stimulated by the abstract of Dr. Bender and his associates, at St. Louis University we reviewed our experience with traumatic transection of the aorta.

From 1979 to the present, we have operated on twenty-six patients, with an operative mortality of 15%. A shunt was used in 54%; the clamp and saw technique was used in the remainder. We have not used a bypass in any of these patients.

One of 12 (8%) of those treated without a shunt died, whereas three of 14 (21%) died in whom a shunt was used. Paraplegia occurred in one patient in the group treated without shunts, and likewise in two in whom the shunt was used.

Of the two patients with paraplegia in the shunted group, one had extensive cerebral injury requiring multiple craniotomies; the other, with a cross clamp time of 37 minutes, had associated subluxation of L-2 and 3. In the single patient of the nonshunted group who had paraplegia, the cross clamp time was 35 minutes. As others have already alluded to today, the use of a shunt was believed, in some instances, to have contributed significantly to the morbidity and mortality of the procedure. The cross clamp time was greater in the shunted group, whether a graft was used or not.

Primary repair was used in 73% of the patients. The cross clamp time with primary repair averaged 34 minutes; it was 57 minutes with graft interposition. We prefer primary repair. It has been used without difficulty in the last 14 consecutive patients.

Our experience supports that which has been presented today. Clamping and sewing is an acceptable technique for managing these patients. It has a lower operative mortality and does not increase the incidence of paraplegia. We would further emphasize the importance and ease of primary repair.

I would like to ask a few questions about the use of the bypass technique. What are the usual cannulation sites? Is an oxygenator used? Is the patient heparinized? What do the authors feel is the indication for this technique?

I commend the authors for an excellent presentation of a fine clinical series.

DR. FRANK C. SPENCER (New York, New York): I will be brief, as there have already been several discussants. The large number of discussants well indicates the importance of this paper.

I certainly agree with Dr. Mattox that dogmatic statements about what is correct and what is incorrect must be avoided in this litigious society. A dogmatic statement, even though it represents an opinion held by less than 5% of practicing surgeons, can esaily be misquoted in a medicolegal trial and have a harmful influence on a lay jury. I am particularly aware of this fact, as I missed opening ceremonies yesterday because I was in court successfully defending myself in a case concerning a patient on whom I operated in 1975, 12 years ago, who subsequently developed a wound infection!

My first question concerns the fact that five of the nine deaths reported, nearly one half of the group, occurred before operation. This fact suggests a delay in surgical treatment that should be correctable. I imagine this delay resulted from not recognizing the diagnosis, or not realizing the necessity of immediate operation. With this type of injury, the constant risk of exsanguination is well recognized; so thoracotomy should be performed as quickly as possible.

Separately, I suppose that proximal control of the aorta was obtained as soon as the thorax was opened. This is best done by opening the pericardium and encircling the aorta before the hematoma surrounding the aortic laceration is touched.

My third comment concerns somatosensory monitoring. For over five years, this has been studied in detail at New York University and reported in several publications by Drs. Cunningham, Laschinger, and others. We consider somatosensory monitoring one of the most important developments in surgery of the thoracic aorta in recent years, although it seems too complicated for routine use with emergency problems, and although several basic questions remain unanswered. The available data, however, are very clear. If the proximal thoracic aorta is occluded and distal aortic pressure remains above 60 mmHg with intact sensory potentials, there seems to be very little risk of paraplegia. However, when sensory potentials disappeared for longer than 30 minutes, in over 50% of the patients in our series, paraplegia developed. Unfortunately, the method is so sensitive that technical mishaps may cause a loss of sensory potentials that are not due to ischemia. The main value of the technique, to date, is during elective surgery in controlled circumstances.

When the aorta is occluded, blood flow to the spinal cord through collateral channels requires a higher perfusion pressure because of the increased vascular resistance. Hence a perfusion pressure higher than 60 mm may be needed in some patients.

Over the past 20 years, the value of different types of aortic shunts has never been consistently proved because the data are inconclusive. These inconsistent results may have resulted from the fact that neither the flow rate through the shunt, nor the distal aortic pressure have usually been measured. A shunt, *per se*, gives no guarantee that an adequate volume of blood is being perfused into the distal aorta. This is the main defect with the ingenious Gott shunt, a significant technical advance in its time but, with the techniques now available, one that should be abandoned. Our data indicate that to maintain sensory potentials, flow through a shunt must be great enough to produce a distal aortic pressure near 60 mm or higher. For this reason, Nipride™ and other vasodilators are potentially dangerous unless very carefully used, because pressure in the distal aorta may be decreased below 60 mm.

In a recent publication, Dr. James Pate of Memphis well summarized previous reports concerning traumatic aortic injuries and paraplegia, and concluded that a shunt provides the greatest safety for the typical patient.

The vast majority of neurologic injuries that occur with traumatic rupture of the aorta are almost certainly due simply to infarction of the spinal cord from ischemia. The principal blood supply to the spinal cord arises between the tenth thoracic and second lumbar vertebra; thus, injuries of the proximal thoracic aorta are far away from the arteries critical to the spinal cord. With severe ischemia, infarction can probably occur in some patients within 20–30 minutes, depending upon the systemic blood pressure and the collateral circulation. Hence, the goal in future studies is either to develop a method of reconstruction of the injured aorta that requires less than 20 minutes of occlusion, or use a shunt that provides a large enough flow of blood to keep distal aortic pressure above 60 mm.

DR. ROBERT B. LEE (Closing discussion): Dr. Mattox, we would agree with virtually all of your statements. The medicolegal consequences of paraplegia are increasingly important. In the literature on this subject, many authors make dogmatic statements regarding spinal cord protection. Unfortunately, a definitive technique for providing fail-safe distal perfusion of the spinal cord has yet to be developed. It must be stated and restated that all methods, whether shunt, bypass, or clamp and sew, have been associated with cases of paraplegia. No method is foolproof.

We have had at least one shunt-related problem. One of our patients with paraparesis had a shunt placed from the left ventricle to the distal aorta. In our opinion, placement of the proximal cannula of the shunt in the left ventricle may result in insufficient distal aortic perfusion. This opinion is supported by the recently published experience of Dr. Marvasti. He states that the difference in the mean pressure in the left ventricle and the aorta may result in insufficient spinal cord perfusion. Also, it can be difficult to place a shunt accurately in the left ventricular apex so that it will function optimally.

We would like to thank Dr. Hardy for another in his series of surgical films. His work in surgical cinematography is always an excellent teaching device. We prefer to sew to the uninjured aorta after resection of the injured portion. Generally, we will resect to normal aorta and place an interposition graft. Virtually all of our patients had interposition grafts. Recently we have repaired two noncircumferential tears of the aorta by primary technique. We think that the decision of whether or not to use primary repair can be made only after the surgeon opens the aorta.

Dr. Grover's first question concerned the use of computed tomography in diagnosis of acute aortic disruption. No large series has been published documenting the treatment of this injury based on CT findings alone. However, CT does have a potential role in evaluation of this injury. Six of our patients had a chest x-ray that was initially interpreted as normal. If one's index of suspicion is high for such patients, then the CT does allow one to see if there is evidence of a mediastinal hematoma. This appears to be the CT scan's major indication at present.

As stated earlier, two of our patients had primary repair without an interposition graft. We would recommend primary repair only for patients with small, noncircumferential tears; we do not recommend it for extensive tears with distraction of the ends of the aorta.

Although nitroprusside will decrease proximal hypertension after aortic clamping, it will also lower vascular resistance and pressure in the remainder of the systemic bed. One must be judicious in using it, so as not to decrease distal perfusion to the spinal cord and kidneys. This decision is best made at the operating table, based on the amount of distention of the left ventricle, as well as pressure in the ascending aorta.

In regards to the BioMedicus™ centrifugal pump: this issue is addressed in a recent article by Dr. Oliver. He documented good results in nine patients in whom he used a heparinless Biomedicus pump. We have not used this modality.

Prioritizing injuries in a Level I trauma center is sometimes difficult. We have to remember that the most crucial injury is usually the thoracic aortic injury. Our data support this concept: despite a high index of suspicion and rapid transport to the arteriography suite, two patients experienced free rupture and exsanguination during arteriography. This fact re-emphasizes the unpredictable and sometimes fatal nature of this injury.

Dr. Kaiser, when we utilize partial bypass, we use the femoral vein to femoral artery technique. We usually reserve this option for patients who have significant metabolic acidosis and no contraindications to heparinization.

Dr. Spencer, we always use a retrograde femoral artery approach for the arteriogram catheter. The literature supports the safety of this technique. We agree that recognition and diagnosis are of the utmost importance.

The use of somatosensory evoked potentials for monitoring spinal cord function is frequently mentioned in the literature and has been mentioned by more than one discussant of this paper. We would agree with Dr. Mattox that this modality is not as useful in the acute setting as it may be in the nonemergency setting. It may have a role in the treatment of patients with an atherosclerotic thoracic aneurysm or coarctation. However, considerable expertise and judgment are required for analyzing the evoked potential data and altering the operative procedure on the basis of that data.

Although we use a shunt to provide distal perfusion for the majority of our patients, at present *no* technique provides the surgeon with certainty that distal organ ischemia and spinal cord injury will be prevented.

The authors would like to thank the Southern Surgical Association for the opportunity to present our data.

Reconstruction of Full Thickness Chest Wall Defects

RAYMOND F. MORGAN, M.D., MILTON T. EDGERTON, M.D., HAROLD J. WANEBO, M.D.,* THOMAS M. DANIEL, M.D.,*
WILLIAM D. SPOTNITZ, M.D.,* and IRVING L. KRON, M.D.*

Over the last 5 years, 14 patients were treated by wide *en bloc* resection of chest wall tumors with primary reconstruction. There were nine females and five male patients with an age range of 31–77 years. All patients had a skeletal resection of the chest wall. An average of 3.9 ribs were resected in the patients treated. In three patients a partial sternectomy was carried out in conjunction with the rib resections. Chest wall skeletal defects were reconstructed with Prolene mesh, which was placed under tension. Soft tissue reconstruction utilized selected portions of the latissimus dorsi musculocutaneous territory with fasciocutaneous extensions beyond the muscle itself. Primary healing was obtained in all patients and secondary procedures were not required. The average hospitalization was 23 days. All patients survived the resection and reconstruction and were alive 30 days after operation. In selected patients the preservation of a portion of the innervated muscle *in situ* or the transfer of the muscle with the preservation of its resting length has maintained the majority of the muscle function.

SUCCESSFUL RECONSTRUCTION of thoracic wall defects should be provided ideally as an immediate one-stage procedure that provides structural stability and secure closure of the integument. Parham described his experience with thoracic resections for tumors of the bony chest wall in 1898.[1] In this monumental review he outlined all of the "cases of resection for malignant tumor of the thoracic skeleton" that he was able to find in the medical literature. The series began in 1778 and carried an overall 29.5% perioperative mortality rate. In his report, he expressed deep gratitude to both Fell[2] and O'Dwyer[3] for their contributions in the field of "intubation and forced respiration."

From the Department of Plastic Surgery, and the Department of Surgery, University of Virginia Medical Center, Charlottesville, Virginia*

Classification of tumors of the thoracic wall occurred during the early 1900s. Tumors of the chest wall such as sarcomas as well as intrathoracic tumors were defined by Lund,[4] Hedblom,[5] and Harrington.[6] By 1933, reviews by authors[4,5,7,8] indicated that more than 300 cases of chest wall resections for metastases as well as primary lung, breast, and rib tumors had been performed.

Chest wall structural stability has been obtained using fascia lata grafts as described by Watson and James.[9] Autogenous rib grafts were later used by Bisgard and Swenson.[10] These were used to reconstruct a resected sternum. They made a very important technical observation about the rib reconstruction in regard to structural stability. They distracted the ribs and placed the grafts under tension to provide firm anchorage for the grafts. Maier[11] advocated large cutaneous flaps from the medial portion of the opposite breast for central defects, and laterally based abdominal wall flaps for defects of the lower thoracic region. However, it is Campbell[12] who deserves a great deal of credit for clearly defining the use of the latissimus dorsi muscle flap for reconstruction of full thickness chest wall defects. He outlined both the nerve and the blood vessel supply through the thoracodorsal system (Fig. 1). He used the muscle to reconstruct an anterior chest wall defect and resurfaced it with a skin graft.

During the 1950s refinements were made in reconstructive techniques. Blades and Paul[13] stated that "large chest wall defects . . . can be treated satisfactorily, regardless of its size." Converse et al.[14] reconstructed a radiation ulcer over the heart with an abdominal flap carried on the forearm. Myre and Kirlin[15] focused their

attention on subtotal sternectomies and advocated only the use of "pectoralis fascia, subcutaneous tissue and skin."

Over the next decade the problems of chest wall reconstruction were continuously examined.[16–18] Chest wall stability continued to be a concern.[19] The use of the omentum in reconstruction was described in 1963 by Kiricuta,[20] and later refined.[21] Although a number of techniques remained in use for chest wall reconstruction, it appeared that the musculocutaneous concept was becoming the most reliable.[22] It was particularly useful after the use of irradiation on the chest wall.[23] The versatility and reliability of the latissimus muscle was

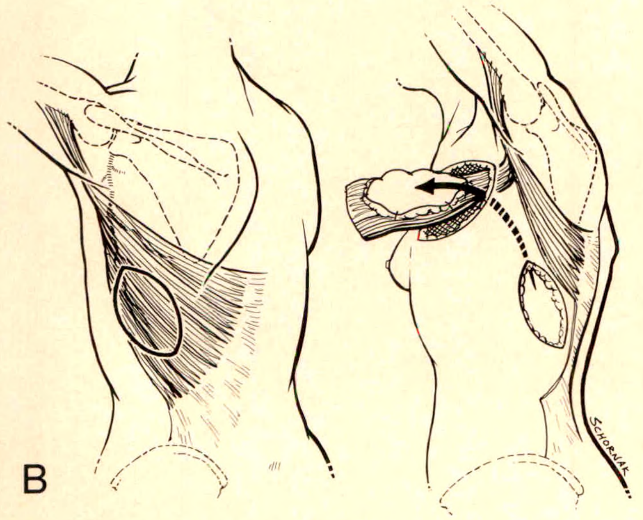

FIG. 3B. A segment of the latissimus dorsi muscle may be selected and transferred with the cutaneous island. This permits a portion of the muscle to remain *in situ* and to continue to function. The reconstructive unit is transferred through the axilla and used on the anterior chest while the donor site may be skin grafted or frequently closed primarily.

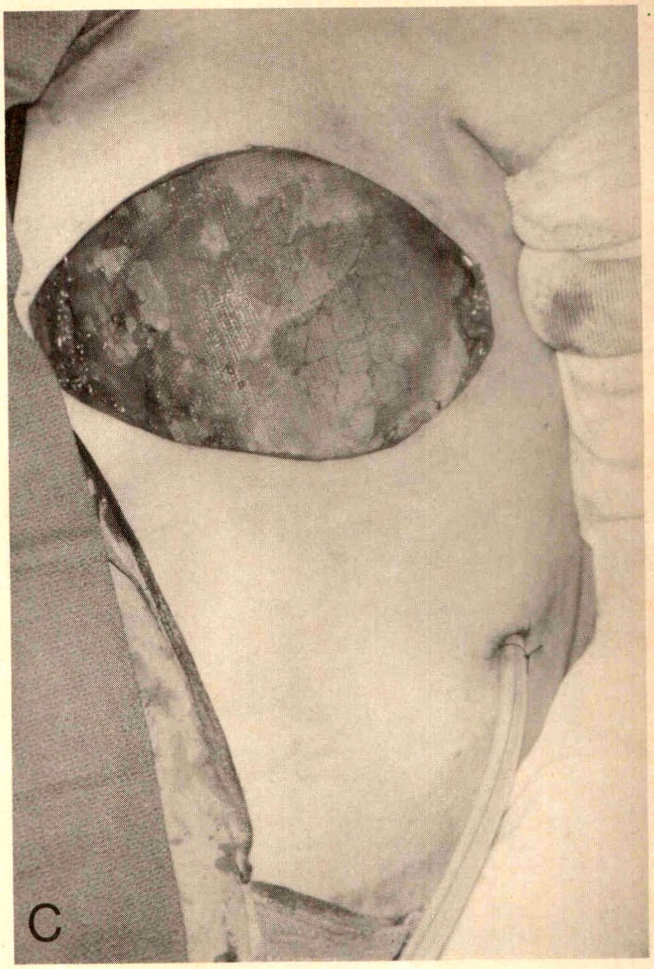

FIG. 3C. The chest wall resection is complete and the Prolene mesh has been placed under tension. The left lung is seen through the Prolene mesh.

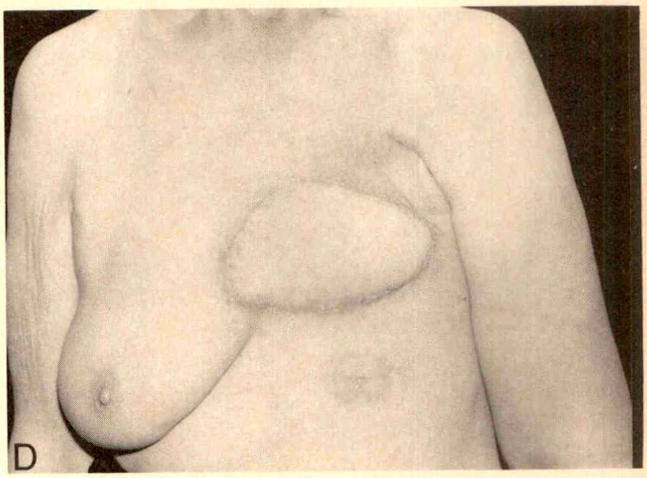

FIG. 3D. Two months after operation the anterior reconstructed chest wound is well healed. A portion of the latissimus muscle remains intact.

reported by Bostwick et al.[24] in a large series of patients. Refinements in the use of musculocutaneous units allowed them to be split into segments.[25] More recently a large series of chest wall reconstructions using a wide variety of techniques was presented with excellent results by Arnold and Pairolero.[26]

Materials and Methods

Between 1982 and 1987 there were 14 consecutive patients at the University of Virginia Medical Center who were treated by full thickness *en bloc* resection of chest wall tumors and immediate reconstruction. The patients were treated jointly by the departments of surgery and plastic surgery. A single method of reconstruction was used in all cases. A latissimus dorsi musculocutaneous flap with fasciocutaneous extensions was used as immediate coverage for the Prolene mesh (Ethicon, Inc., Somerville, NJ) that was used to obtain structural stability of the chest wall.

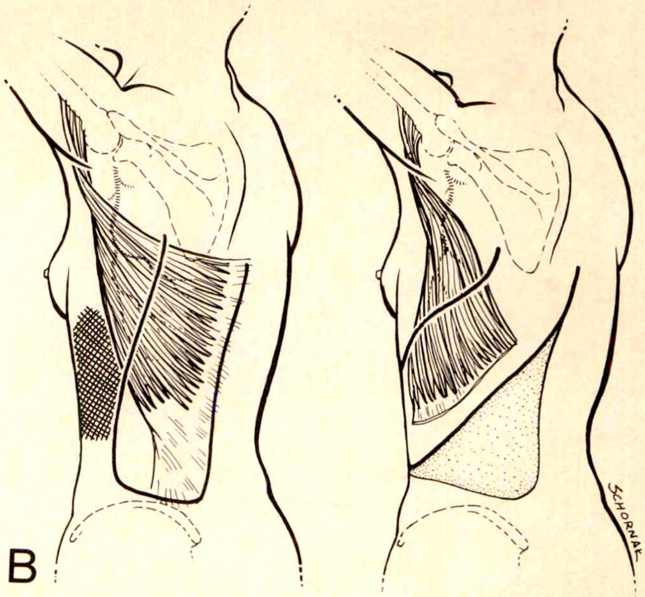

FIG. 4B. The entire latissimus dorsi muscle with an inferior extension to the level of the iliac crest was used to reconstruct this anterior and lateral chest wall defect.

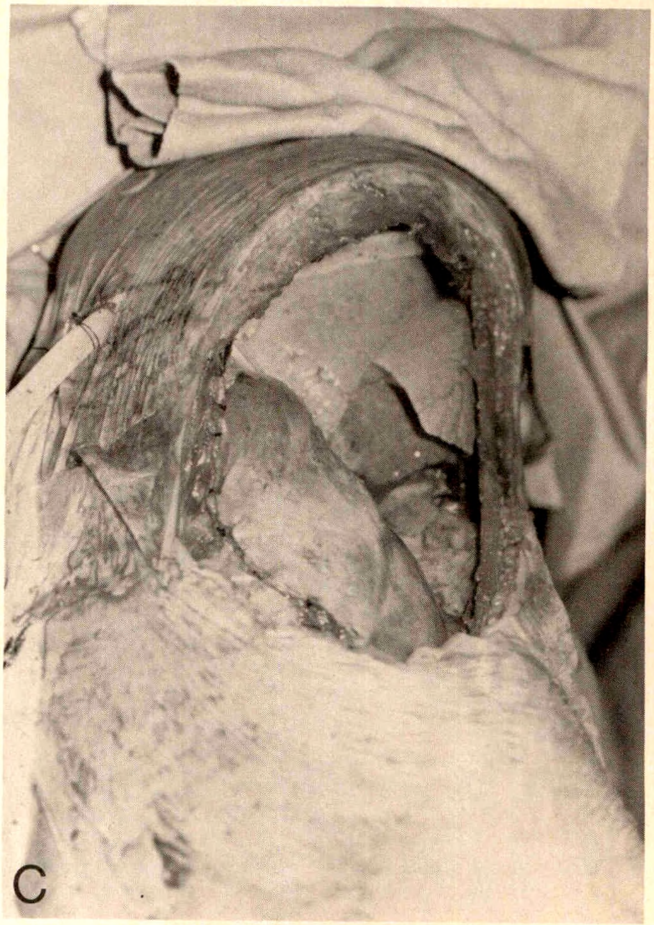

FIG. 4C. The surgical defect created prior to reconstruction reveals the left lung in the upper portion of the defect and the repaired diaphragm in the lower anterior section of the surgical defect.

There were nine females and five males treated. The age range was 31 to 77 years. The mean hospitalization time was 23 days. The pathology of the lesions was varied. They included paraganglioma, malignant schwannoma, malignant fibrous histocytoma, aggressive fibromatosis, radiation necrosis, squamous cell carcinoma (2), fibrosarcoma (2), and breast carcinoma (5). The anatomic location of the defects included anterior (7), lateral (4), and posterior (3). The resection included excision of the bony skeleton in each case. The range of the ribs resected was 2 to 6 with a mean of 3.9 ribs. In three cases the resection included a partial sternectomy in conjunction with the rib resection.

Results

Each of the 14 patients had a single immediate reconstruction with a segmental or total latissimus dorsi musculocutaneous flap. Structural stability was obtained with Prolene mesh. Primary healing was obtained and no secondary procedures were required. All patients were alive at 30 days after operation, and no deaths were attributed to either the resection or the reconstruction. Follow-up study has ranged between 9 and 51 months with a mean of 27.5 months. Successful reoperation for the evaluation of a recurrence was possible in one case 8 months after operation without difficulty. Eleven patients are alive as of this writing.

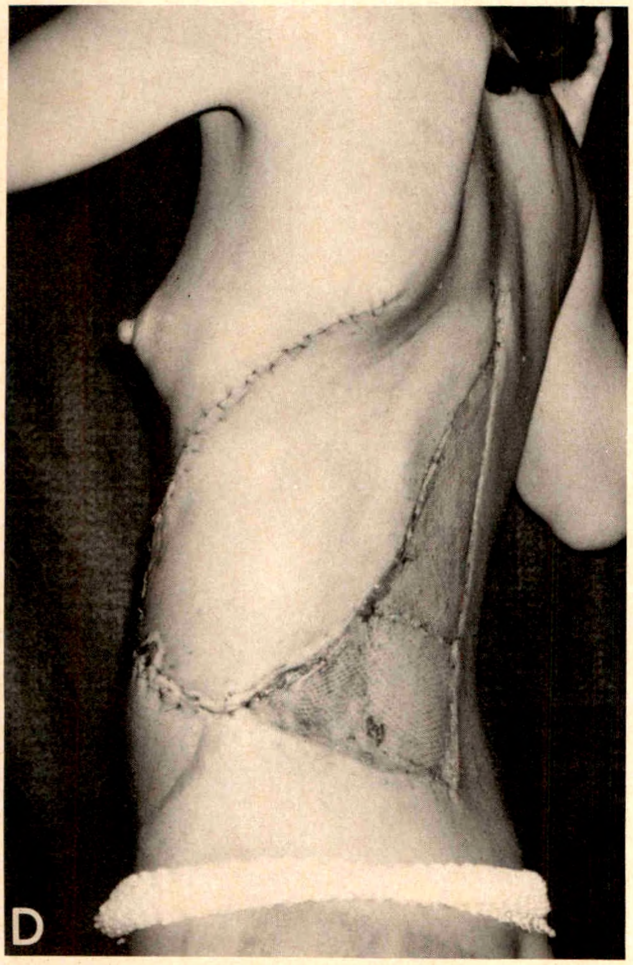

FIG. 4D. One week after operation the musculocutaneous flap is seen and the donor defect has been skin grafted.

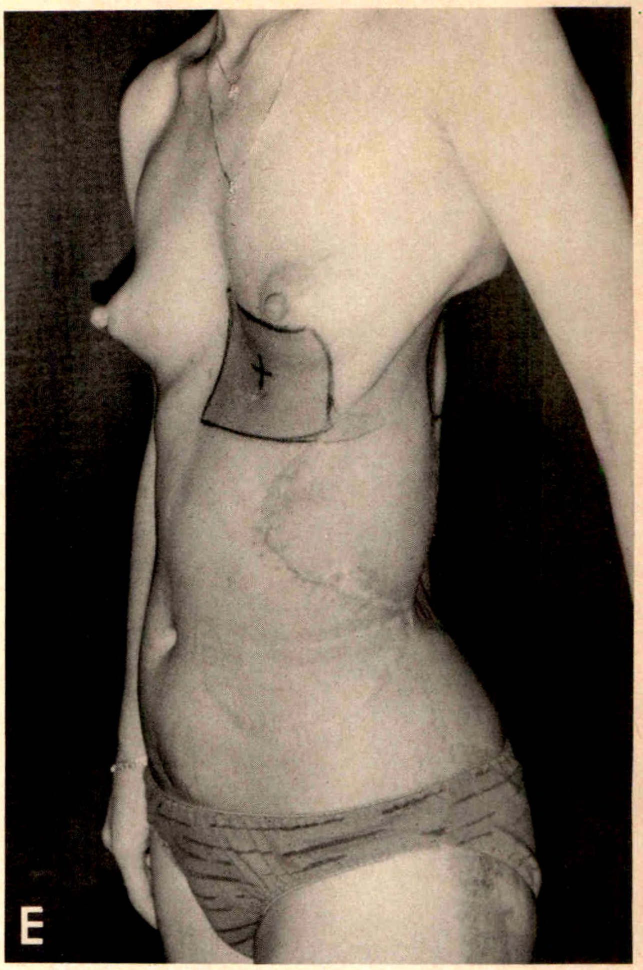

FIG. 4E. The postoperative therapy included irradiation. The anterior port outlined here. The posterior port was designed over the proximal portion of the latissimus dorsi flap. The radiation therapy was tolerated well by the reconstructive musculocutaneous flap.

Functional evaluation was obtained in two patients postoperatively. The Cybex (Cybex, Ronkonkoma, NY) data reduction computer was used and demonstrated that maintaining the correct resting length of the muscle in the transposed position or permitting a segment of innervated muscle to remain *in situ* will preserve a significant amount of total arm adduction power and endurance.

Discussion

This current report confirms the versatility and reliability of the lattissimus dorsi musculocutaneous flap.

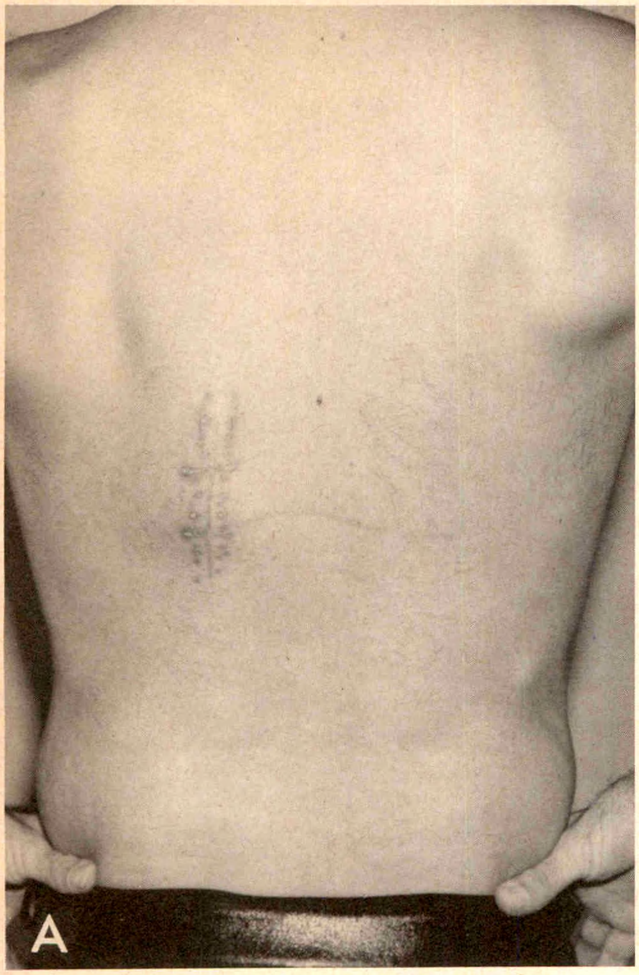

FIG. 5A. This 34-year-old man presented with a biopsy proven aggressive fibromatosis tumor. The left paraspinous location can be seen.

Fasciocutaneous extensions of the flap afford a larger reliable reconstructive unit. Dependable reconstruction allows adequate resection and optimal treatment.

The structural stability of the chest wall can be obtained with the use of Prolene mesh placed under tension. A method used by the authors places the mesh and sutures it firmly in place while the rib approximator remains in position (Fig. 2). When the rib approximator is removed the mesh increases greatly in tension. This greatly reduces the amount of paradoxical motion during spontaneous respiration. Total excision of the sternum was not undertaken in any of the cases presented, and mesh alone may not be adequate in that situation. Prolene mesh has proven to exhibit several desirable characteristics. This surgical mesh is a knitted polypropylene nonabsorbable synthetic. Because the mesh is knitted, it provides for elasticity in both directions. The fiber junctions are interlinked, and, therefore, the mesh is less likely to fracture when flexed as the more rigid metallic mesh are prone to do. The placement of the mesh under appreciable tension is essential in order to obtain structural stability. This polypropylene mesh exhibits not only high tensile strength, but also a high burst strength of approximately 250 lb/in.[2] Previous reports have shown this material to perform well in both reconstruction of the abdominal wall[27] in more than 100 patients and in reconstruction of the chest wall.[26,28]

Anterior upper chest reconstruction may be accomplished with a segmental portion of the muscle (Fig. 3). The superior or inferior portion of the muscle may be transferred with the appropriate amount of subcutaneous tissue for the reconstruction. The portion of the muscle that remains in place continues to function and aid in arm adduction. Cutaneous units of 8–10 cm in width allow primary donor site closure without difficulty.

Surgical defects of the lower anterior chest may require transfer of the entire muscle (Fig. 4). Fasciocutaneous extensions posteriorly to the midline and inferiorly to the level of the iliac crest may be required to resurface

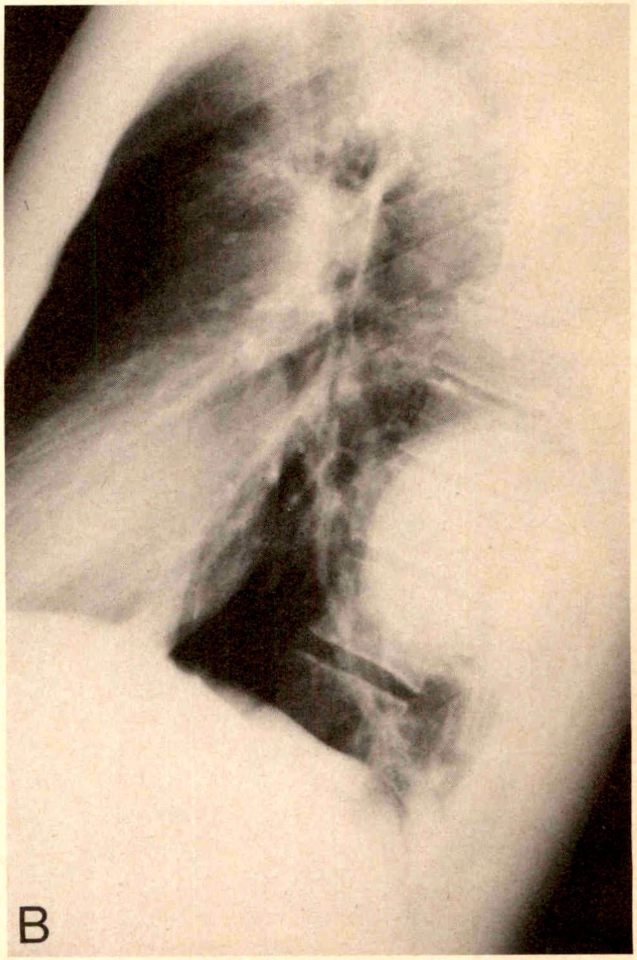

FIG. 5B. The lateral chest roentgenogram shows clearly the intrathoracic extent of the well-circumscribed tumor.

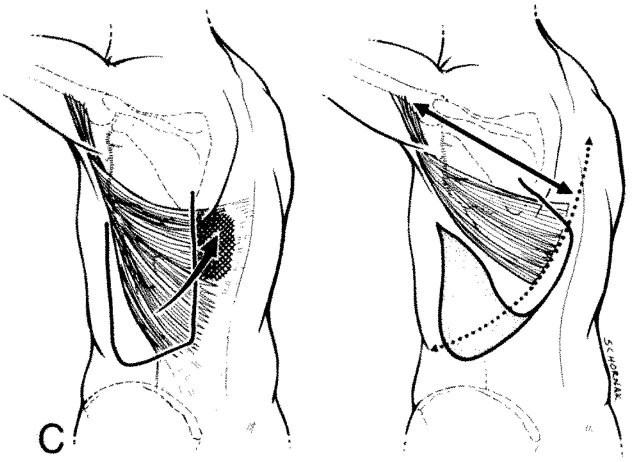

FIG. 5C. The entire origin of the left latissimus muscle was included in the reconstruction. The resting length of the muscle was marked with sutures prior to transfer. The arc of the muscle was drawn on the patient preoperatively and the distal end of the muscle was secured to the surgical defect along that arc. The tension of the muscle was adjusted so that the previously placed sutures were at the same interval after the transfer of the muscle.

the defect. If radiation therapy is contemplated in the postoperative treatment, the location of the ports should be considered. The proposed site for irradiation should be secured with well vascularized tissue. Placement of the transposed muscle in a position that approximates the normal resting length of the innervated muscle can preserve both function of the muscle and the contour of the posterior axillary fold.

Posterior chest wall defects may be reconstructed using the same principles (Fig. 5). Fasciocutaneous extensions inferiorly and anteriorly may be required. If the arc of rotation of the muscle from its insertion on the

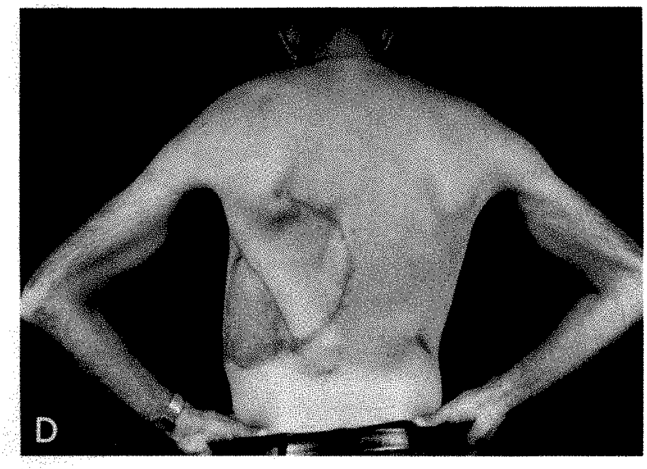

FIG. 5D. After operation the flap is well healed. The arms are in extension with forced adduction, and the preservation of the posterior axillary line by the latissimus muscle can be seen. Postoperative testing confirmed that the function of the muscle remained intact.

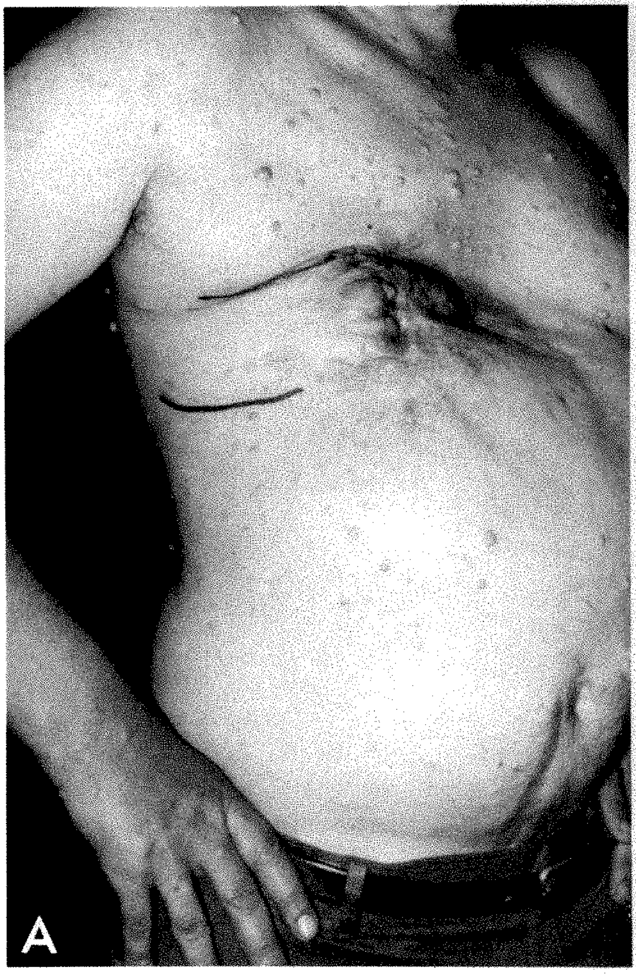

FIG. 6A. This 43-year-old man presented after several unsuccessful attempts at surgical excision of a malignant nerve sheath tumor. The site of the previous surgical scarring on the right chest can be seen at the inferior margin of the pectoralis major muscle.

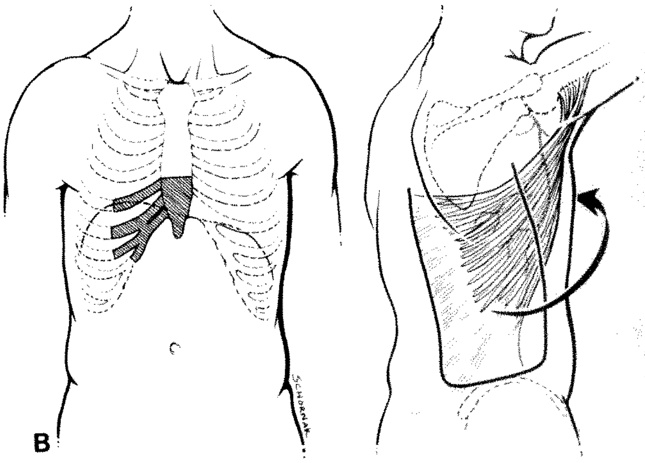

FIG. 6B. The area of resection consists of the inferior third of the sternum as well as the sixth through the ninth ribs. The entire right latissimus muscle with the anterior, inferior, and posterior fasciocutaneous extensions included was transferred to reconstruct the anterior chest defect.

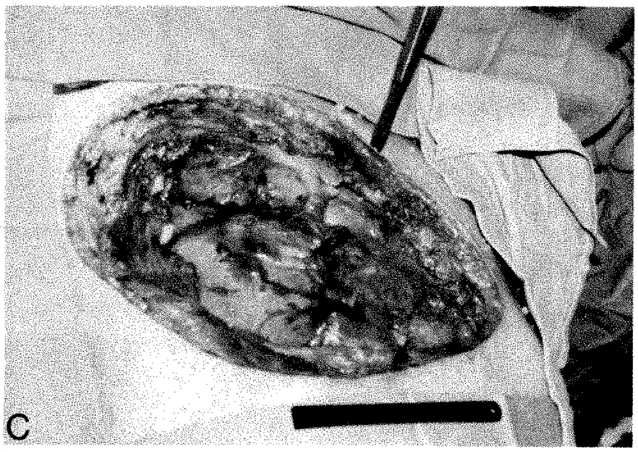

FIG. 6C. The right anterior chest and abdominal defect prior to placement of the mesh.

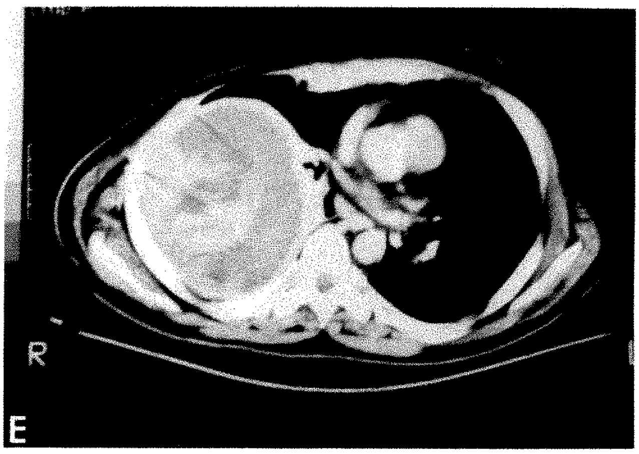

FIG. 6E. Eight months after operation a recurrence of the tumor in the right lower chest was confirmed by CT scan. The tumor can be seen extending into the right thorax.

humerus to its origin is traced, the placement of the muscle in the defect to be reconstructed can be adjusted to maintain the muscle at the appropriate resting length. Prior to transfer the muscle can be marked with sutures at fixed intervals of a few centimeters. Then, when the muscle is relocated the sutures can be readjusted to the appropriate intervals. Preservation of adduction power has been documented as well as the maintenance of the posterior axillary line contour.

Large anterior chest wall defects including a portion of the sternum may also be reconstructed (Fig. 6). The entire ipsilateral latissimus territory, which extends to the midline posteriorly, the middle axillary line anteriorly, and the iliac crest inferiorly, can be used. If a partial sternectomy is included in the skeletal resection, the reconstructive unit may extend across the midline to the contralateral side. If reexploration of the site is necessary for evaluation of a recurrence, the entire musculocutaneous unit can be elevated to allow access to the skeletal defect without difficulty. Uneventful healing can be anticipated.

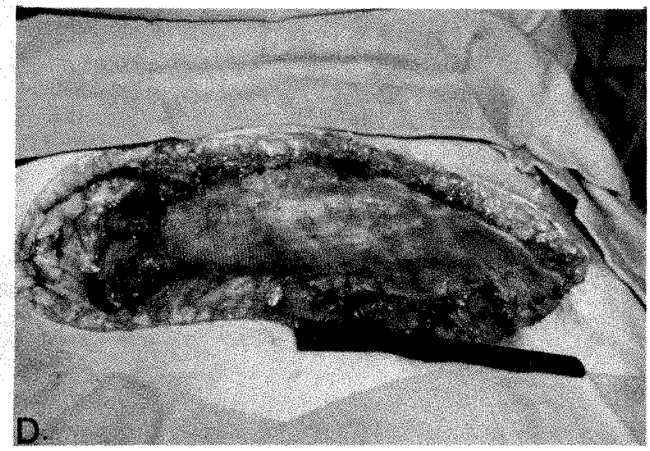

FIG. 6D. After the rib approximator was removed the Prolene mesh remains under tension.

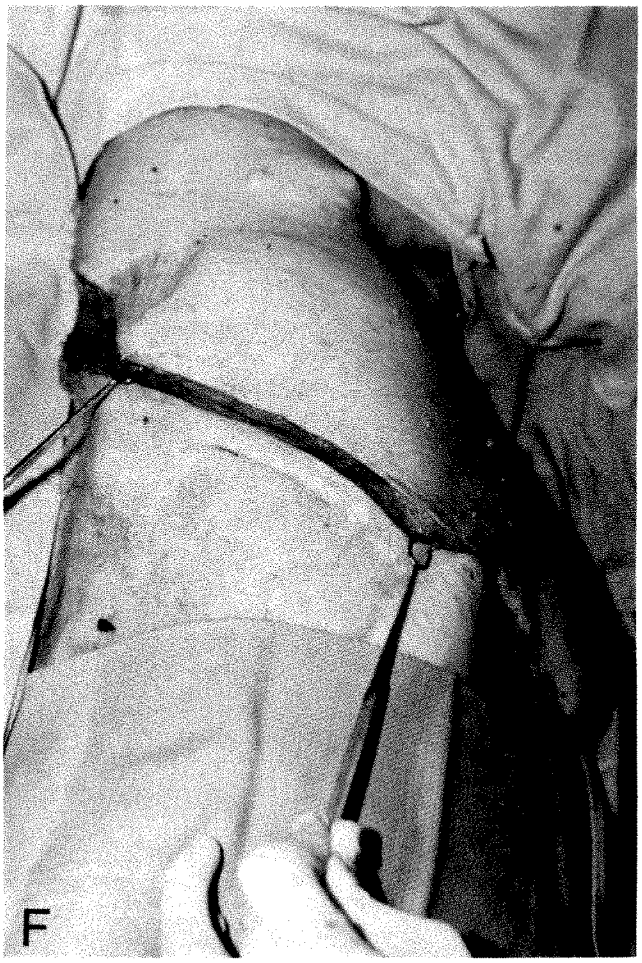

FIG. 6F. Reexploration of the wound was undertaken, and the entire musculocutaneous flap was elevated at its lower margin.

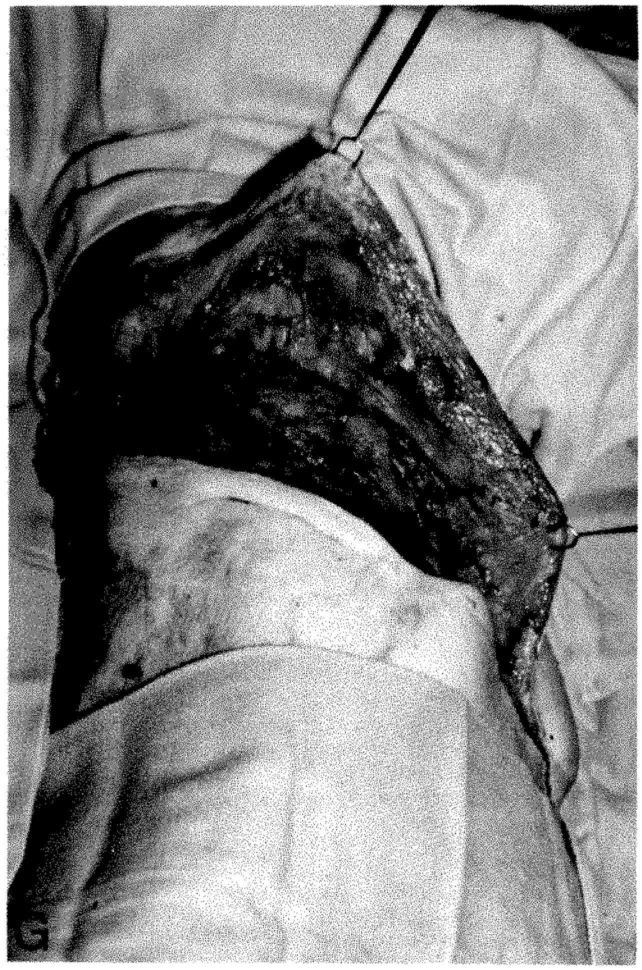

FIG. 6G. The elevation of the flap permitted evaluation both of the right chest as well as the right upper abdomen. Multiple biopsies revealed the tumor to be widely disseminated in the abdominal cavity.

Conclusion

The authors' experience with 14 consecutive patients who had full thickness chest wall excision and primary reconstruction with a single technique, latissimus dorsi musculocutaneous flap with Prolene mesh, is reviewed. The coordinated efforts of the thoracic and plastic surgeons provided optimal care for the patient. Segmental portions of the muscle that are permitted to remain *in situ* or total transfer of the muscle with the correct resting length permit continued documented adduction function of the latissimus dorsi muscle.

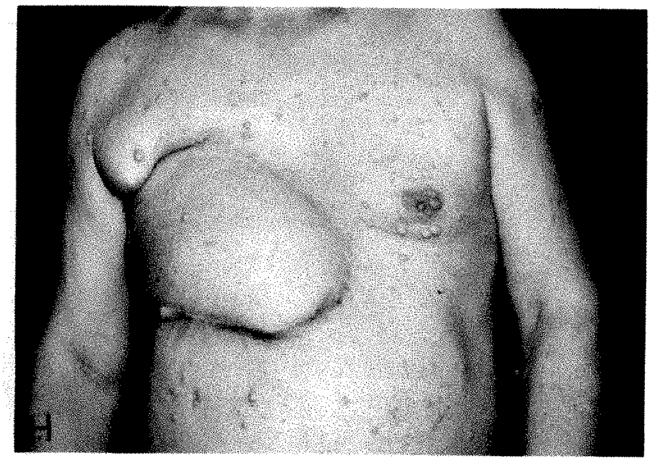

FIG. 6H. After operation the healing was uneventful and the length of the musculocutaneous flap across the midline can be seen.

DISCUSSION

DR. JOHN J. COLEMAN, III (Atlanta, Georgia): I appreciate the opportunity to participate in this meeting as a guest and to discuss Dr. Morgan's paper.

(Slide) During the last ten years at the Emory University Affiliated Hospitals, we have had the opportunity to deal with a number of complex thoracic defects caused either by trauma, tumor resection, or infected thoracotomy and sternotomy. Our approach has included the latissimus dorsi as an important part of this overall reconstructive plan, but we have developed, by necessity, a slightly different approach for encompassing the possibility of either reoperation secondary to tumor recurrence that might involve the previous reconstruction, or partial or complete failure of the reconstruction effort.

This approach is primarily a Plan A with a Plan B, and occasionally a Plan C, and it has been facilitated by the realization that most of these large flat muscles of the chest wall, either anterior or posterior, have an axial long blood supply, as Dr. Morgan demonstrated, the thoracodorsal pedicle in the latissimus dorsi, and also a segmental blood supply; and in the case of the latissimus, there is the paravertebral perforators of the intercostals.

This is also true of the pectoralis, and, to a lesser degree, the rectus abdominis and the trapezius. The following patient demonstrates this approach:

This is a 44-year-old woman with a three times-recurrent cystosarcoma phylloides, the resection of which required removal of four ribs, repair with Proline, and soft tissue coverage, which was accomplished by a rotation flap of the abdominal wall, based on the perforators from the anterior intercostals.

This approach allowed preservation of the contralateral internal mammary vessels, and also allowed a good repair. Preserving the vessels was, as it turned out, important because about 9 months later, the patient had a large recurrence, as might be suspected with a tumor such as this. This recurrence was addressed by a second resection and transfer of the entire abdominal wall based on the internal mammary vessels.

This approach has been used in ten major anterior chest wall resections, with the inferior epigastric kept in reserve for a possible microvascular anastomosis. So understanding the anatomy in this area allows us considerable flexibility. Our plan has generally been to start with a local musculocutaneous flap and then move, if necessary, to a regional musculocutaneous flap, and finally, to use the omentum or free tissue transfer as a last resort.

I have several questions. First, have you been limited at all by the body habitus of the patient? We have occasionally seen that the latissimus is excellent in a tall, thin patient, but in a short patient or a patient with a large barrel chest, the arc of rotation is limited. What is the safe fasciocutaneous extension of the latissimus flap, and is this limited at all by previous axillary radiation? As you mention in your manuscript, five of the patients had previous breast cancer. We have had some problems with the fasciocutaneous extension of the latissimus, and would appreciate your insight into this.

DR. RALEIGH R. WHITE (Temple, Texas): I think the authors of this paper are to be greatly congratulated. It is a pleasure and a true benefit for me to see a paper that will help me directly in my practice when I return home. I truly appreciate the wonderful demonstration of that extended flap.

I rise to ask one specific question regarding the material that we have been using recently to repair these larger defects with a more solid material, Gortex sheeting.

It seemed good to isolate the abdominal and the thoracic cavities in these larger defects with a more solid piece of material rather than porous mesh. I wonder if you have any recent experience with that and if you would have any advice for us on its use.

DR. P. G. ARNOLD (Rochester, Minnesota): I congratulate the authors on a paper that is both well presented and well written. I also appreciate having the chance to review it earlier.

In my own practice, I am in a special situation working with Dr. Peter Pairolero, who is a busy thoracic and vascular surgeon. We do a great deal of work together.

During the last ten years, we have had the opportunity to work together on about 152 of these chest wall tumors. In a third of this group we simply took the tumor out and closed the skin again after dealing with the skeletal defect.

In the 112 that were closed with muscle flaps, half of these were latissimus dorsi muscle. (In seven instances we used another muscle in addition to the latissimus dorsi muscle). Primarily we used the pectoralis muscle or another local muscle in the other half. We used a mesh if, in 84 patients, it was a clean wound (Prolene was used in 53 patients and Gortex in 32). Gortex is nice when you need a watertight closure. It costs more, but they both have advantages.

My question to Dr. Morgan is: Is the latissimus dorsi muscle flap your first choice for a chest wall reconstruction, regardless of where the tumor is located? If it is an anterior tumor, is that still your first choice?

I realize that, geometrically speaking, as long as the axis and arc is present, we can move muscles and skin from any part of the chest to any other part of the chest. Do you have a "recipe" that you go through in your own mind in deciding what to use in your reconstruction? Obviously, this presentation is about just one particular muscle flap, and I would be interested in what your other options were, and if for some reason they failed as a flap.

DR. WILLIAM D. SPOTNITZ (Closing discussion). I would like to thank the discussants for their excellent questions and Dr. Morgan for the opportunity of closing this paper at the 100th anniversary meeting of the Southern Surgical Association.

In response to Dr. White's question, we have not had a great deal of experience with Gortex, but we have read of its use and agree with Dr. Arnold that it is a very pliable, good material. It certainly restricts the flow of air and fluid, although it is semipermeable, and it would be the material of choice if one were trying to perform a diaphragmatic repair.

In response to Dr. Coleman, we agree that the patient's body habitus needs to be considered in the choice of this type of flap, and we agree that patients who are excessively obese and short or barrel chested may require additional consideration in use of the latissimus dorsi flap.

We have not had experience in using this flap in patients who have had axillary irradiation. As illustrated by Dr. Morgan, we have used this flap in patients who needed postoperative radiotherapy, and when the ports were specifically designed to take into account the use of the muscle flap, those patients have not had problems. However, I can't comment on those patients who have had preoperative irradiation to the axilla.

We agree with Dr. Arnold that patients who have limited rib resections on the order of 1 to 2 ribs can certainly have their skin closed and don't need these dramatic, beautiful flaps that Dr. Morgan has shown.

In closing I would like to comment that in terms of our choice of flaps, we do agree that with small anterior defects high up on the chest, we would attempt to use pectoralis major flaps first, and that inferiorly we might very well use rectus abdominus flaps. Also, as Dr. Arnold has previously recommended, we keep the omentum as an alternative and secondary means of closing defects that are not successfully treated with musculocutaneous flaps.

LMC LUTHERAN MEDICAL CENTER

SURGEONS

Full-time and part-time salaried positions available for general and intensive in-patient care and ambulatory care in active general surgical service. Includes sub-specialty opportunities in orthopedics, neurosurgery, urology. Supervision of interns/residents and physicians assistants. Flexible schedules available for surgeon developing professional practice or studying for board certification.

Applicants must be licensed to practice in New York State or have completed at least three years training in an approved residency and be eligible for limited permit. We offer a competitive compensation package and opportunity for professional growth. Interested physicians should send C.V. or call **Dr. Michael R. Golding, Director of Surgery, (718) 630-7350.**

Lutheran Medical Center is a modern, progressive 532-bed community teaching hospital serving the neighborhoods of Bay Ridge/ Sunset Park in Brooklyn; convenient to expressways and Verrazano Bridge.

LUTHERAN MEDICAL CENTER
150 55th St, Brooklyn, NY 11220

An equal opportunity employer

Cardiac/Thoracic Surgeon

Marshfield Clinic Department of Thoracic and Cardiovascular Surgery is seeking an additional surgeon experienced in cardiac and general thoracic surgery to join its five member group. Marshfield Clinic is a private group practice consisting of 260 physicians representing all surgical and medical specialties. The Clinic is physically attached to a 524 bed acute care teaching hospital. A Surgical Residency Program, University of Wisconsin Medical School affiliation, large Medical Research Foundation plus major secondary and tertiary level patient referral base contribute to a very stimulating environment. For additional information, please send curriculum vitae to:

FIFTEENTH ANNUAL SYMPOSIUM ON CURRENT CRITICAL PROBLEMS IN VASCULAR SURGERY

November 18-20, 1988
WALDORF-ASTORIA HOTEL
NEW YORK, NEW YORK

PROGRAM
Our Fifteenth Symposium will address the current state of the art in Vascular Surgery and Vascular Radiology. We will also focus on New Horizons or areas into which Vascular Surgeons and Vascular Specialists may expand their activities. Our course will deal with material that is essential knowledge for Vascular Surgeons and others who wish to keep their practice consistent with all that is new and important in the treatment of Vascular Disease. The latest significant advances, changing concepts in diagnosis and management, pressing controversies and new techniques, agents and diagnositc modalities are the CRITICAL PROBLEMS AND NEW HORIZONS IN VASCULAR SURGERY that will be covered in depth. The course will also provide a number of important updates and reevaluations.

ACCREDITATION
Albert Einstein College of Medicine / Montefiore Medical Center designates this continuing medical education activity for 22 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association.

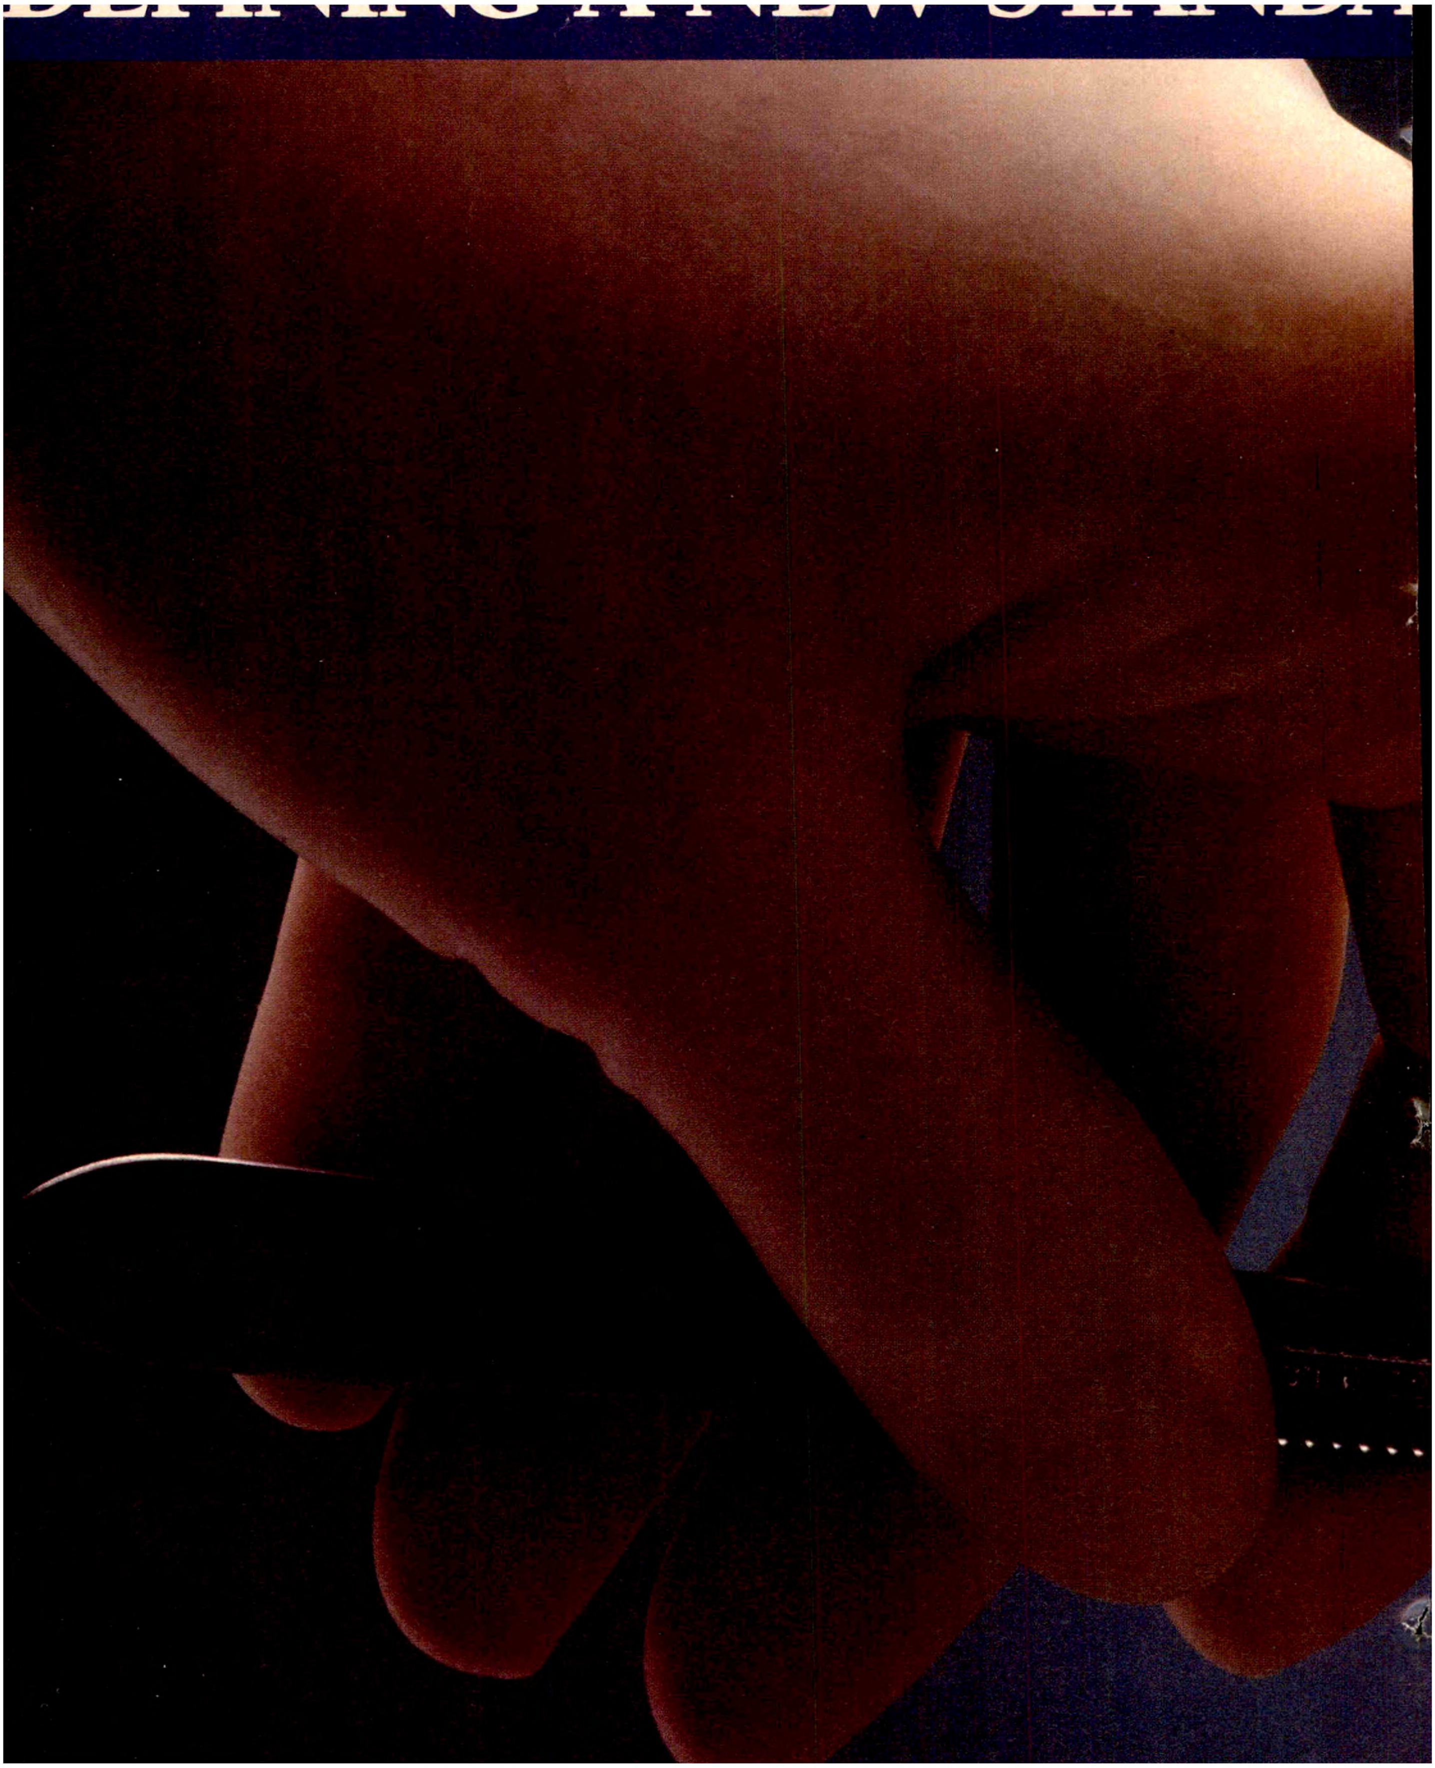
FACULTY AND REGISTRANTS
A faculty of over seventy renowned clinicians and researchers from the United States and Europe will share their insights with a distinguished audience of more than seven hundred surgeons and radiologists, who are interested predominantly in the treatment of Vascular Disease. This combination of registrants and faculty and the fast paced 10-15 minute presentations, panels and workshops are the key elements which, year after year, make the SYMPOSIUM uniquely valuable and exciting.

SOCIAL EVENTS
The Fifteenth Symposium will offer registrants and accompanying family members and friends an exciting selection of daytime programs, museum and gallery visits, and evenings at the theatres and concert halls of New York. A luncheon and evening reception at the Waldorf-Astoria are part of this year's program.

REGISTRATION
Tuition: $550.00 for practicing physicians; $395.00 for fellows and residents.

For further information contact: Office of Continuing Medical Education

Albert Einstein College of Medicine / Montefiore Medical Center
3301 Bainbridge Avenue, Bronx, New York 10467 **(212) 920-6674**



DEFINING A NEW STANDA

For Infection Following
Complicated Abdominal Surgery

BETTER THAN AMINOGLYCOSIDE COMBINATIONS FOR MOST PATIENTS

☐ Anaerobic coverage of clindamycin or metronidazole plus

☐ Gram-negative coverage of an aminoglycoside plus

☐ Gram-positive coverage of cefazolin plus

☐ Enterococcal coverage of ampicillin plus

☐ Tolerability profile characteristic of beta-lactam antibiotics

*when indicated organisms are suspected at indicated sites

PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product. Before initiating therapy with PRIMAXIN, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, other beta-lactams, and other allergens. If an allergic reaction to PRIMAXIN occurs, discontinue the drug. Serious hypersensitivity reactions may require epinephrine and other emergency measures.

Please see Brief Summary of Prescribing Information.

INTRAVENOUS

PRIMAXIN®

(Imipenem-Cilastatin Sodium|MSD)

Contraindications: PRIMAXIN is contraindicated in patients who have shown hypersensitivity to any component of this product.

Warnings: SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (anaphylactic) REACTIONS HAVE BEEN REPORTED IN PATIENTS RECEIVING THERAPY WITH BETA LACTAMS. THESE REACTIONS ARE MORE APT TO OCCUR IN PERSONS WITH A HISTORY OF SENSITIVITY TO MULTIPLE ALLERGENS.

THERE HAVE BEEN REPORTS OF PATIENTS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE HYPERSENSITIVITY REACTIONS WHEN TREATED WITH ANOTHER BETA LACTAM. BEFORE INITIATING THERAPY WITH 'PRIMAXIN', CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, OTHER BETA LACTAMS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION TO 'PRIMAXIN' OCCURS, DISCONTINUE THE DRUG. SERIOUS HYPERSENSITIVITY REACTIONS MAY REQUIRE EPINEPHRINE AND OTHER EMERGENCY MEASURES.

Pseudomembranous colitis has been reported with virtually all antibiotics, including PRIMAXIN; therefore it is important to consider its diagnosis in patients who develop diarrhea in association with antibiotic use. This colitis may range in severity from mild to life threatening.

Mild cases of pseudomembranous colitis may respond to drug discontinuance alone. In more severe cases, management may include sigmoidoscopy, appropriate bacteriological studies, fluid, electrolyte, and protein supplementation, and the use of a drug such as oral vancomycin, as indicated. Isolation of the patient may be advisable. Other causes of colitis should also be considered.

Precautions: *General*—CNS adverse experiences such as confusional states, myoclonic activity, and seizures have been reported during treatment with PRIMAXIN, especially when recommended dosages were exceeded. These experiences have occurred most commonly in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function. However, there have been reports of CNS adverse experiences in patients who had no recognized or documented underlying CNS disorder or compromised renal function.

Patients with severe or marked impairment of renal function, whether or not undergoing hemodialysis, had a higher risk of seizure activity when receiving maximum recommended doses than those with no impairment of renal function; therefore, maximum recommended doses should be used only where clearly indicated (see DOSAGE AND ADMINISTRATION).

Patients with creatinine clearances of ≤5 mL/min/1.73 m² should not receive PRIMAXIN unless hemodialysis is instituted within 48 hours.

For patients on hemodialysis, PRIMAXIN is recommended only when the benefit outweighs the potential risk of seizures.

Close adherence to the recommended dosage and dosage schedules is urged, especially in patients with known factors that predispose to convulsive activity. Anticonvulsant therapy should be continued in patients with known seizure disorders. If focal tremors, myoclonus, or seizures occur, patients should be evaluated neurologically, placed on anticonvulsant therapy if not already instituted, and the dosage of PRIMAXIN re-examined to determine whether it should be decreased or the antibiotic discontinued.

As with other antibiotics, prolonged use of PRIMAXIN may result in overgrowth of nonsusceptible organisms. Repeated evaluation of the patient's condition is essential. If superinfection occurs during therapy, appropriate measures should be taken. While PRIMAXIN possesses the characteristic low toxicity of the beta-lactam group of antibiotics, periodic assessment of organ system function during prolonged therapy is advisable.

Drug Interactions—Since concomitant administration of PRIMAXIN and probenecid results in only minimal increases in plasma levels of imipenem and plasma half-life, it is not recommended that probenecid be given with PRIMAXIN.

PRIMAXIN should not be mixed with or physically added to other antibiotics. However, PRIMAXIN may be administered concomitantly with other antibiotics, such as aminoglycosides.

Carcinogenesis, Mutagenesis, Impairment of Fertility—Gene toxicity studies were performed in a variety of bacterial and mammalian tests *in vivo* and *in vitro*. The tests were: V79 mammalian cell mutation assay (PRIMAXIN alone and imipenem alone), Ames test (cilastatin sodium alone), unscheduled DNA synthesis assay (PRIMAXIN), and *in vivo* mouse cytogenicity test (PRIMAXIN). None of these tests showed any evidence of genetic damage.

Reproduction tests in male and female rats were performed with PRIMAXIN at dosage levels up to 8 times the usual human dose. Slight decreases in live fetal body weight were restricted to the highest dosage level. No other adverse effects were observed on fertility, reproductive performance, fetal viability, growth, or postnatal development of pups. Similarly, no adverse effects on the fetus or on lactation were observed when PRIMAXIN was administered to rats late in gestation.

Pregnancy—Pregnancy Category C: Teratogenicity studies with cilastatin sodium in rabbits and rats at 10 and 33 times the usual human dose, respectively, showed no evidence of adverse effect on the fetus. No evidence of teratogenicity or adverse effect on postnatal growth or behavior was observed in rats given imipenem at dosage levels up to 30 times the usual human dose. Similarly, no evidence of adverse effect on the fetus was observed in teratology studies in rabbits with imipenem at dosage levels at the usual human dose.

Teratology studies with PRIMAXIN at doses up to 11 times the usual human dose in pregnant mice and rats during the period of major organogenesis revealed no evidence of teratogenicity.

Data from preliminary studies suggest an apparent intolerance to PRIMAXIN (including emesis, inappetence, body weight loss, diarrhea, and death) at doses equivalent to the average human dose in pregnant rabbits and cynomolgus monkeys that is not seen in nonpregnant animals in these or other species. In other studies, PRIMAXIN was well tolerated in equivalent or higher doses (up to 11 times the average human dose) in pregnant rats and mice. Further studies are under way to evaluate these findings.

There are, however, no adequate and well-controlled studies in pregnant women. PRIMAXIN should be used only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers—It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when PRIMAXIN is administered to a nursing woman.

Pediatric Use—Safety and effectiveness in infants and children below 12 years of age have not yet been established.

Adverse Reactions: PRIMAXIN is generally well tolerated. Many of the 1,723 patients treated in clinical trials were severely ill and had multiple background diseases and physiological impairments, making it difficult to determine causal relationship of adverse experiences to therapy with PRIMAXIN.

Local Adverse Reactions—Local adverse clinical reactions that were reported as possibly, probably, or definitely related to therapy with PRIMAXIN were: phlebitis/thrombophlebitis (3.1%), pain at the injection site (0.7%), erythema at the injection site (0.4%), vein induration (0.2%), infused vein infection (0.1%).

Systemic Adverse Reactions—The most frequently reported systemic adverse clinical reactions that were reported as possibly, probably, or definitely related to PRIMAXIN were: nausea (2.0%), diarrhea (1.8%), vomiting (1.5%), rash (0.9%), fever (0.5%), hypotension (0.4%), seizures (0.4%) (see PRECAUTIONS), dizziness (0.3%), pruritus (0.3%), urticaria (0.2%), somnolence (0.2%).

Additional adverse systemic clinical reactions reported as possibly, probably, or definitely drug related occurring in less than 0.2% of the patients or reported since the drug was marketed are listed within each body system in order of decreasing severity: *Gastrointestinal*—pseudomembranous colitis (see WARNINGS), hemorrhagic colitis, gastroenteritis, abdominal pain, glossitis, tongue papillar hypertrophy, heartburn, pharyngeal pain, increased salivation; *CNS*—encephalopathy, tremor, confusion, myoclonus, paresthesia, vertigo, headache, psychic disturbances; *Special Senses*—transient hearing loss in patients with impaired hearing, tinnitus; *Respiratory*—chest discomfort, dyspnea, hyperventilation, thoracic spine pain; *Cardiovascular*—palpitations, tachycardia; *Renal*—oliguria/anuria, polyuria; *Skin*—erythema multiforme, facial edema, flushing, cyanosis, hyperhidrosis, skin texture changes, candidiasis, pruritus vulvae; *Body as a Whole*—polyarthralgia, asthenia/weakness.

Adverse Laboratory Changes—Adverse laboratory changes without regard to drug relationship that were reported during clinical trials or reported since the drug was marketed were: *Hepatic*—increased SGPT, SGOT, alkaline phosphatase, bilirubin, and LDH; *Hemic*—increased eosinophils, positive Coombs test, decreased WBC and neutrophils, including agranulocytosis, increased WBC, increased platelets, decreased platelets, decreased hemoglobin and hematocrit, increased monocytes, abnormal prothrombin time, increased lymphocytes, increased basophils; *Electrolytes*—decreased serum sodium, increased potassium, increased chloride; *Renal*—increased BUN, creatinine; *Urinalysis*—presence of urine protein, urine red blood cells, urine white blood cells, urine casts, urine bilirubin, and urine urobilinogen.

NOTE: Due to the high antimicrobial activity of PRIMAXIN, it is recommended that the maximum total daily dosage not exceed 50 mg/kg/day or 4.0 g/day, whichever is lower.

How Supplied: PRIMAXIN is supplied as a sterile powder mixture in vials, infusion bottles, and single-dose ADD-Vantage®† vials containing imipenem anhydrous and cilastatin sodium as follows: 250 mg imipenem equivalent and 250 mg cilastatin equivalent; 500 mg imipenem equivalent and 500 mg cilastatin equivalent.

Caution: The suspension from vials is not for direct infusion.

Vein Cuff Interposition Prevents Juxta-Anastomotic Neointimal Hyperplasia

WILLIAM D. SUGGS, M.D., HORACE F. HENRIQUES, M.D., and RALPH G. DEPALMA, M.D.

From the Department of Surgery, George Washington University Medical Center, Washington, D.C.

This study sought to minimize juxta-anastomotic neointimal hyperplasia (JNIH) following the use of polytetrafluoroethylene (PTFE) conduits. PTFE anastomoses to canine carotid arteries (noncuff grafts) were compared with grafts with vein cuffs interposed proximally and distally between the graft and native artery. This technique has been suggested clinically for below-knee PTFE femoropopliteal reconstruction. Twelve dogs received aspirin for 1 week before operation, which was continued after each animal received bilateral cuff and noncuff 4-mm PTFE grafts. At sacrifice, after 3–12 weeks, graft patency was assessed and luminal diameters measured with ophthalmic calipers at three sites along the anastomoses and 1 mm proximal or distal to graft toe (A′ diameter). Specimens were perfusion fixed at arterial pressure for gross and histologic study; selected arteries were additionally fixed with 4% buffered glutaraldehyde, stored at 4 C, and examined immunochemically using antimyosin antibody immunopurified for smooth muscle. Overall patency of noncuff grafts in 11 long-term surviving dogs was 4 of 11; patency of the cuff grafts was 7 of 11. Regardless of graft thrombosis, antibody positive cellular proliferation occurred mainly at noncuffed PTFE anastomoses. Luminal encroachment was predominantly due to subintimal proliferation of cells highly reactive to smooth muscle derived antibody. JNIH was most prominent 1 mm distal to the graft toe (A′ distal diameter). Average A′ for noncuff grafts was 1.82 mm ± 0.97 SEM; average A′ diameter for cuff grafts was 3.41 mm ± 0.74 SEM ($p < 0.001$). Vein cuff inhibition of proliferation of smooth muscle or cells derived from smooth muscle possibly relates to wider distribution of kinetic energy (less compliance mismatch) or to interposition of venous endothelium.

AN IMPORTANT CAUSE of arterial prosthetic failure is the development of neointimal fibrous proliferation.[1] This process causes stenoses commonly located just proximal and distal to the graft–artery anastomosis in juxta-anastomotic locations. Juxta-anastomotic neointimal hyperplasia (JNIH) causes reduction of flow and subsequent graft failure. The cellular and mechanical factors promoting JNIH are still incompletely understood. Hemodynamic factors,[1,2] graft–artery compliance mismatch,[3] chronic endothelial injury,[4] and pannus ingrowth[5] have all been implicated.

JNIH is common to all types of grafts; however, it has been particularly troublesome with small caliber polytetrafluorethylene (PTFE) grafts. Miller et al.[6] proposed using an interposition vein cuff at the distal anastomosis of PTFE grafts to infrageniculate arteries. The senior author (RDP) has also used vein cuffed anastomoses to PTFE in limb salvage procedures to replace failed vein grafts. Patencies were somewhat longer than might be expected.

This study tested the hypothesis that interposition vein cuffs might prevent JNIH and improve patency of small caliber PTFE grafts. An experimental model was developed to compare vein cuff interposition with standard end-to-side bypass. Stenoses due to JNIH were quantitated; JNIH was mainly due to proliferation of smooth muscle or cells derived from smooth muscle. Moreover, vein cuff interposition between small caliber PTFE grafts and indigenous artery inhibited JNIH.

Materials and Methods

Twelve mongrel dogs weighing 20–25 kg of both sexes (8 males, 4 females) were used. Subjects were treated according to *The Guide for Care and Use of Laboratory Animals,* NIH Publication 8523, 1985. After a period of conditioning and quarantine, all dogs were given 325 mg of aspirin by mouth daily for 7 days before surgery. Aspirin administration was continued after operation until the animals were killed at intervals from 3 weeks to

A. Control: Anastomosis to Artery
B. Experimental: Vein Cuff Interposition

FIGS. 1A and B. *A*. Control: PTFE to artery anastomoses. *B*. Experimental: interposition of vein cuff.

12 weeks. Before operation, the dogs received cefazolin (Eli Lilly and Co., Indianapolis, IN) 500 mg intravenously and 500 mg intramuscularly for 5 days after operation. The dogs were initially anesthetized with Biotal®, 20 mg/kg intravenously (Boeringer Ingelheim Animal Health Inc., St. Joseph, MO) and endotracheal intubation was carried out.

Under nitrous oxide and fluoroethylene anesthesia, bilateral neck incisions were made. Both common carotid arteries were dissected for a length of 10 cm. Heparin, 50 units/kg body weight, was administered intravenously. The external jugular vein was dissected and two 6-mm portions of this vein were harvested without distention or irrigation for use as interposition vein cuffs.

On one side, as a control, a 6-cm length of externally supported lightweight 4-mm PTFE graft (GORE-TEX®) was anastomosed in an end-to-side fashion. This artery was then ligated in its center portion. On the opposite side, a vein cuff test site, 6-mm beveled vein cuffs were anastomosed to the indigenous artery in an end-to-side fashion. A 6-cm length of externally supported PTFE was then anastomosed end-to-end to the proximal and distal vein cuffs and the artery similarly ligated. All anastomoses were performed with continuous sutures of 7-0 polytetrafluorethylene using loupe magnification. Graft insertion angles approximated 30° and the anastomoses measured 1–1.3 cm in length. Figure 1 shows the model diagrammatically.

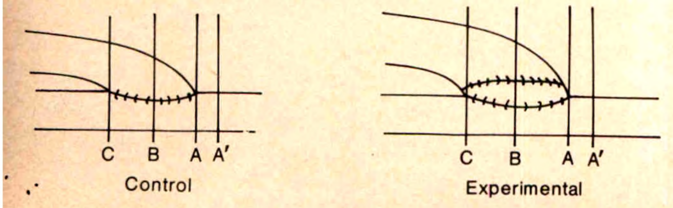

FIG. 2. Cross-sections of anastomotic diameters for measurement and histologic examination. Section A′, shown here in a distal anastomosis, was always taken 1 mm from toe of graft.

The patency of the noncuffed and cuffed grafts was compared in individual animals and among the entire group using selected anastomotic diameters. To obtain arterial diameters approximating those occurring *in vivo* arteries were perfusion fixed at an arterial pressure of 100 mmHg using 2.5% buffered glutaraldehyde (Electron Microscopy Sciences, Fort Washington, PA). Arterial specimens were then resected for luminal measurement, histologic, and immunohistochemical examinations. Ophthalmic calipers were used to measure the luminal diameters of each section. Figure 2 shows details of the anastomotic configuration of the cuffed and noncuffed grafts and the cross-sectional diameters measured. The following graft–arterial sections were obtained: (1) A′—1 mm distal or proximal from the toe of the anastomosis; (2) A—the toe of the anastomosis; (3) B—midportion of the anastomosis; (4) C—heel of the anastomosis.

Eleven dogs were killed by initiating general anesthesia and perfusing the carotid arteries with glutaraldehyde solution. These procedures were used on all dogs except for one animal dying of a stroke within 24 hours of operation. At postmortem examination the stroke in this animal was found to be due to acute thrombosis of the noncuffed carotid graft side. Measurements from this subject were not used in further analyses. No other strokes occurred. The measurements of luminal diameters were averaged and compared for significant differences using Student's t-test.[7] Just before sacrifice and after perfusion, each grafted arterial segment was examined for patency; the incidence of graft patency to graft closure in the two groups was also compared.

Proximal and distal arterial rings comprising A′, A, B, and C diameters were sectioned and examined microscopically after staining with hematoxylin and eosin. In addition, cuffed and noncuffed arterial specimens from two dogs were fixed in 4% glutaraldehyde, frozen at −70 C, and fixed in OCT compound (Miles Scientific, Napeville, IL). These frozen sections were cut in 8-μm thicknesses and stained with antimyosin antibody purified using immunoaffinity chromatography for smooth muscle myosin (Technicon Instruments Corp., Glendale, CA). Immunofluorescent antibody staining was performed using the methodology described in the Kalstead Fluorescence Autoantibody Manual.[8]

Results

The most severe juxta-anastomotic neointimal hyperplasia occurred at the A and A′ segments. The degree of stenosis caused by neointimal hyperplasia was most prominent in the proximal and distal segments of noncuffed PTFE to artery anastomoses and was most severe at distal anastomoses. Table 1 compares mean diameters of proximal and distal A and A′ sites. Stenoses secondary to JNIH were quantitatively most significant at the proximal A ($p < 0.002$) and distal A′ ($p < 0.001$) cross-sectional areas of the noncuffed grafts. The remaining segments B and C were not found to exhibit statistically significant differences in lumen diameters either proximally or distally.

The immunochemical and histologic examinations showed this process mainly to be due to proliferation of smooth muscle or cells derived from smooth muscle. Little or no reactivity to smooth muscle-derived myosin occurred at the junction of the PTFE to the beveled vein cuffs. Figure 3 demonstrates intense reactivity to smooth muscle-derived myosin at noncuff PTFE artery anastomoses, whereas at the vein cuff–PTFE anastomoses (Fig. 4), cellular proliferation is scanty. Figure 5 shows typical juxta-anastomotic neointimal hyperplasia at the distal A′ segment.

Table 2 shows comparative patencies over time in each animal. The vein cuff grafts were open more frequently; however, this difference cannot be considered statistically in a sample this size with individual variations in thrombogenicity, which will be later considered. Examination of the grafts and correlation with the degree of intimal stenosis demonstrated that graft closure and the process of neointimal hyperplasia were sometimes nonconcordant. Graft thrombosis occurred despite antiplatelet therapy, and on three occasions occurred in the absence of demonstrable stenoses due to neointimal hyperplasia.

TABLE 1. *Average Juxta-Anastomotic Diameters (mm) ± SEM (N = 11)*

	Proximal A	Distal A
Cuff	3.81 ± 1.16	3.18 ± 1.04
SE difference	0.50 $p < 0.002$	0.45 $p < 0.069$
Noncuff	1.73 ± 1.19	2.27 ± 1.50

Cuff	3.09 ± 0.74	3.41 ± 0.74
SE difference	0.47 $p < 0.053$	0.34 $p < 0.001$
Noncuff	2.10 ± 1.27	1.82 ± 0.97

Discussion

Vein cuff interposition between PTFE and native artery clearly inhibited JNIH. Moreover, JNIH was mainly due to proliferation of smooth muscle or cells derived from smooth muscle as demonstrated by immunohistochemical reactivity. It is probable that vein cuff interposition tended to minimize unfavorable hemodynamic forces promoting neointimal proliferation, as suggested by Imparato et al.[1] over a decade and a half ago and later by LoGerfo et al.[9] The current observations support the thesis that hemodynamic factors promote JNIH at stereotypic sites just proximal or distal to arterial graft anastomoses, *i.e.*, at the A and A′ sections just at the toe or just distal to the toe of the grafts.[10] Clinically, neointimal hyperplasia is also seen at these

sites and occurs in a variety of arterial locations and grafts, although JNIH related to PTFE in particular has been characterized extensively.[11]

The stenoses in this experimental model appeared mainly to be due to myointimal proliferation. Presumably there is later alteration of smooth muscle cells to cells capable of producing fibrous tissue. The cellular changes promoting the myoproliferative responses are known to begin within several days.[4] The mass of tissue consisted mainly of proliferating smooth muscle or smooth muscle-derived cells, insofar as could be judged in this study rather than by transformation of fibrin clot. However, further studies would be needed to characterize unequivocally all cell types that occur at the junction of the graft and indigenous artery.[12] In the current study the stenotic process was well developed as early as 3 weeks after graft implantation.

Another similarity between the experimental findings in this study and clinical experience was that patency and the development of neointimal hyperplasia were not necessarily concordant. We initially assumed that antiplatelet therapy might retard or neutralize the factor of individual thrombogenicity, as suggested by Freeman and associates.[13] Recent work by Kaplan et al.,[14] however, demonstrated that individual thrombogenic tendencies dominate canine models. It is likely that the aspirin therapy did not eliminate blood clotting factors in the hostile environment of these small caliber grafts. Although 7 of 11 of the cuffed grafts remained patent as opposed to 4 of 11 of the noncuffed grafts, this difference cannot be considered significant due to sample size and known variations in individual thrombogenicity.

Differences in blood coagulability, we believe, account for discrepancies between patency and the development of JNIH both in experimental models and clinically. It is highly probable that increased individual thrombogenicity existed in some of the experimental animals in the current study. This increased thrombogenic potential can give rise to graft thrombosis independently of the development of JNIH. Using the recently described techniques to estimate canine thrombogenicity,[14] we now measure prospectively these factors in this experimental model. Similar measurements might be valuable in humans as well when small diameter prosthetic grafts are required.

Quite separately from the variable of thrombogenicity, vein cuff interposition clearly minimized myointimal proliferation in a quantitatively significant fashion. Figure 6 diagrams a hemodynamic hypothesis based on minimizing graft–artery compliance mismatch as wider dispersion of kinetic energy. It is postulated that the vein cuff more widely distributes kinetic energy from the relatively noncompliant graft to the indigenous artery. The net result is less mechanical arterial wall injury at the end-to-side graft artery junctions, damping cellular responses caused by unfavorable hemodynamics. It is also possible that interposition of venous endothelium in the

cuff might have mitigated mitagenic factors from the graft, secreted prostacycline or other substances, and exerted still other effects in a purely cellular rather than in a mechanical manner. Currently, experiments are being performed on thrombogenically characterized animals to measure effects of mechanical factors and further define cellular factors that might phenotypically modulate smooth muscle proliferation and secretion.

DISCUSSION

DR. STANLEY O. SNYDER (Norfolk, Virginia): The problem of unsatisfactory long-term patency results with prosthetic grafts at the below-knee popliteal or tibial position has long plagued vascular surgeons. Compliance, the percentage of radial change in response to pressure, is actually an expression of the vessel's elasticity.

Abbott and Bouchier-Hayes[1] demonstrated in canine studies a direct relationship between decreasing graft compliance and decreasing graft patency rates at 2 weeks and 3 months. By decreasing the compliance mismatch between the conduit and the arterial vessel at the distal anastomosis, there was reduction in impedance—that is, a reduction in the opposition to pulsatile flow and subsequent interference with energy propagation.

A 1986 study by Beard et al.[2] demonstrated hemodynamic advantage by adding a compliant vein cuff at the distal anastomosis of vessels 2 mm in diameter. They reported a significant decrease in anastomotic resistance, with an increasingly significant increase in blood flow as blood pressure rose.

Dr. DePalma and his colleagues have conducted a significant research study implicating smooth muscle cells as the culprit in the development of new intimal hyperplasia, previously thought to result from turbulent flow at the site of compliance mismatch of the end-to-side distal anastomotic site.

In 1962, Dr. Andrew Dale[3] reported 16 patients using Teflon to vein composite grafts, but abandoned the technique when only one graft remained patent after 1 year. A similar but slightly modified operative technique first performed in the early 1970's by Drs. Friedman and DeLaurentis, and Rhee,[4] and Drs. Linton and Wirthlin[5] and Dr. Jerry Lord, et al.,[6] produced improved results.

At the 1983 Southern Surgical Association meeting in Hot Springs, Dr. Robert Batson presented a Linton patch technique for overcoming the compliance mismatch, and reported a cumulative patency of 65% after 36 months follow-up.

In 1986, Dr. Buth et al.,[7] of the Netherlands, reported excellent short-term results with tibial bypasses using the umbilical vein graft combined with the short vein cuff; they believed that this technique prevented the thick umbilical vein edges from protruding mechanically in the small arterial lumen.

In Norfolk we have used the beveled end-to-end technique with Goretex™ and as much vein as can be harvested to form a composite graft. Our initial report of 1981[8] revealed a significant increase in patency for 68 composite grafts, compared with 89 all-Goretex grafts.

A follow-up study of 1984[9] again produced satisfactory long-term cumulative patency in 128 composite grafts.

Dr. DePalma's technique will be quite valuable when no adequate vein is available, yet if care is taken to avoid kinking, twisting, or angulation, wouldn't it be preferable to have the Gortex to vein anastomosis and its associated compliance mismatch farther removed from the distal anastomotic site, as it is in the standard composite technique?

DR. MALCOLM PERRY (Nashville, Tennessee): Neointimal hyperplasia is not a new entity, but the term may be a misnomer, because it is a fibrous proliferation, not an increase in the number of endothelial cells. The widespread use of PTFE has directed our attention to these lesions, since they occur more frequently with these grafts.

The authors have shown that these fibrous lesions appear early, usually in the host artery, opposite the graft. That location and the relative inelasticity of the PTFE have suggested to some people that hemodynamic factors play a central role in the etiology.

This thesis is further strengthened by the observation that inline grafting with an end-to-end anastomosis is rarely compromised, regardless of the material that is used, although fibrosis may be seen from time to time if there are diameter differences.

Through immunofluorescent techniques, Dr. DePalma and Dr. Suggs found that factors from the media appeared to be involved. In the past, we had thought that platelet-derived growth factor was the cause of neointimal hyperplasia. The antiplatelet agents have not lived up to their billing, and have not proved successful in preventing neointimal hyperplasia. This suggests that the more recently described endothelial growth factor may be at fault.

I would like to ask Dr. DePalma if he subscribes to this theory. As one reviews this manuscript, one finds that neointimal hyperplasia was not usually present. Medial hyperplasia is predominant, but some of the slides show intimal proliferation.

Can those mediators that incite cellular growth be blocked? The antiplatelet agents that are available have not been effective in this area.

This is an important study, and although clearly these are preliminary results and lack statistical validity, I would encourage the authors in their line of investigation.

DR. PAUL E. STANTON, JR. (Johnson City, Tennessee): I would like to congratulate the authors on this very well prepared and presented piece of work.

I have another problem area of interest, however, possibly associated with the PTFE graft, that I would like to put as a query to the authors: the PTFE graft's potential association with the acceleration of true atherogenesis downstream from the area of anastomosis.

At one of the national vascular meetings about 3 years ago and as reported in the "Journal of Vascular Surgery" at approximately the same time, Dr. Allan Callow pointed out a series of cases that he had in which, with above-knee femoral-popliteal bypasses, there was what he believed an inordinate number of patients coming back with failure of the graft due to downstream atherosclerotic disease in the midpopliteal segment.

Last year at our institution at East Tennessee State, I had the opportunity to review approximately 150 failed above-knee femoral-popliteal bypasses. It was the philosophy of a previous vascular surgeon at our institution to perform a great number of these above-knee grafts, and interestingly, as we took a large number of early failed grafts (6 months–2 years) back to the operating room and restudied not only the anastomotic area, but the midpopliteal segment, most of these were failing not due to intimal hyperplasia, but due to downstream true atherosclerotic disease.

Presently we have in our laboratory an ongoing series of investigations with an atherogenic animal model in which, over a period of several months, we are evaluating the intimal hyperplastic effects at the anastomotic site, and the downstream effects of accelerated atherogenesis, as well.

To this day, at six months, we have not seen any accelerated atherogenesis downstream. I would like, at this time, to query Dr. DePalma and his associates on whether at the 'A' primed area (or more distally, or perhaps even in the venous cuff segment) they are seeing any early fatty deposition or evidence of fatty streaking that might forebode atherogenic changes.

If they have not noted this, I would recommend that in the future phase of this study this be looked at specifically.

DR. WILLIAM D. SUGGS (Closing discussion): We agree with the points Dr. Snyder has presented. The clinical use of vein cuffs is limited to situations in which there is an inadequate length of vein for a composite graft or for a vein graft failure due to inadequate diameter. In all instances, we would prefer a vein graft for below-knee limb salvage procedures.

In answer to Dr. Perry, with routine histology, we do not see a thick layer of endothelial cells, but note subendothelial collections of cells as smooth muscle or smooth muscle-derived cells.

In answer to Dr. Stanton's question, we have not observed fatty deposits in the A′ diameter, nor have we observed in this model the development of fatty deposits more distally.

We do believe, however, that this experimental model provides a valuable means of studying both neointimal fibroplasia and atherosclerosis in juxta-anastomotic areas.

One Hundred Years of Surgical Management of Hyperthyroidism

ARLIE R. MANSBERGER, JR., M.D.

From the Medical College of Georgia, Augusta, Georgia

"FOR THOUSANDS OF YEARS goiter has been a familiar malady. An unsightly and frequently fatal disease, it was accepted as an inoperable affliction or dispensation of Providence in communities where it prevailed and paraded the streets exciting the curiosity of the populace in towns where it was unusual. The sufferers sought relief from suffocation, difficulty in swallowing, failure of the heart, and from a distressing disfigurement. Thus, this conspicuous tumor of the neck was a perpetual challenge to the physician, and to the surgeon a stigma as well."[1]

Attempts by the ancients to remove diseased thyroid glands were fraught with danger, disaster, and death for patient and surgeon alike. The brief accounts that follow epitomize that dilemma. "In the year 1595, an empiric attempted to remove a goiter in a case of a ten year old girl. She died under the operation, and the surgeon was imprisoned."[1] In quoting a case attempted around 1770, "Such a severe hemorrhage occurred that the surgeon was obliged to stop in the middle of the operation. He was unable to control the hemorrhage by any means. The patient died eight days later."[1] In another case of the same era, "After several fruitless attempts at ligation of the arteries, the severe hemorrhage was controlled by compression day and night during eight days by persons alternating with each other at the task."[1]

When immediate death was not due to hemorrhage, delayed mortality rate of septic etiology was not uncommon. Nathan R. Smith's patient, Mrs. Wells of Prince George's County Maryland on whom the "Emperor" removed a large goiter with ulceration of the dependent skin, died from sepsis on the 13th day after surgery in 1835.[1]

By 1866, the situation was apparently though slightly improved as evidenced by this statement from Samuel D. Gross: "Can the thyroid gland when in the state of enlargement be removed with a reasonable hope of saving the patient? Experience emphatically answers, no! . . . If a surgeon should be so fully foolhardy as to undertake it . . . every step he takes will be environed with difficulty, every stroke of his knife will be followed by a torrent of blood, and lucky will it be for him if his victim live long enough to enable him to finish his hard butchery . . . no honest and sensible surgeon would ever engage in it."[2]

Lister's discovery of antisepsis in 1867 and the development of and use of hemostatic forceps in European clinics (circa 1870) heralded a new era of thyroid surgery. However, in spite of the fact that Theodor Kocher[1] the father of thyroid surgery who in 1872 had became a professor of surgery at the University of Berne at age 31, had accomplished the excision of 101 goiters during the first decade of his tenure with a mortality rate of 12.8% and by 1889 added an additional 250 patients to that series with a mortality rate of only 2.4%; goiter surgery in the United States was a victim of "lag fever."[2]

Souchon[3] in 1896 devoted a few brief comments to the thyroid gland. Souchon stated that the cause of the goiter was unknown but that some believed goiter to be an infectious disease the parasite of which was in the water. He commented that, "the true treatment of goiter consists of extirpation, especially if it grows and if pressure symptoms are serious."[3] It is of interest that Souchon did not mention any specific personal experience with operations upon the thyroid gland in his treatise.

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

Reprint requests: Arlie R. Mansberger, Jr., M.D., Medical College of Georgia, Augusta, GA 30912.

Submitted for publication: December 10, 1987.

Charles H. Mayo stated,

> "But a few years ago a reviewer of surgery of this country would have said that the United States was singularly free of diseases of the thyroid gland . . . The surgery of the neck never seemed to enjoy the popularity of that of the abdomen, and goiter operations are not even today sought by the majority of surgeons. Those who were competent did not sufficiently often encourage operative relief until the absolute necessity rendered the mortality so high as to be almost prohibitive. The lay impression became such that operative measures were permitted only in the most advanced cases while semi-surgical, medical, mechanical, and electrical treatment flourished. In most cases, death came slowly and was looked upon as a relief from suffering, a result which satisfied everybody; but the death which follows operation is a shock to all and in but few instances is there a consideration of the fact that medical treatment had previously failed. Neither is the urgent necessity of the operation or the desperate condition of the patient taken into account, but the death has made a debit against the surgical side. Especially is this true in cases of exophthalmic goiter."[4]

In 1906 Mayo reported on the surgical treatment of goiter based upon 300 personal operations[5] and by 1908, he presented a series of 1000 operations upon the thyroid gland.[6] By the time of that presentation, it was clear that the technical problems associated with ordinary goiters, at least in the larger clinics, were no longer barriers to surgical removal. This was true in spite of the large size of many that the patients carried with them to the surgical arena. In Mayo's series[6] of 1000 goiter operations, 574 were cases of simple colloid or diffuse adenomatous goiter with but four deaths, a mortality rate of 0.7%. Crile agreed with Mayo's observations and emphasized that in simple goiters one scarcely accepts a fatality from excision.[7] Both Crile and Mayo agreed that in goiters of the exophthalmic variety, much remained to be done with regard to the reduction of the morbidity and mortality rates associated with operation as a coincidence.

The rigors and awesome responsibilities borne by our predecessors' attempts to reduce the mortality rate of those patients with advanced cases of hyperthyroidism can only be appreciated by a thorough perusal of their efforts as documented in the *Transactions of the Southern Surgical Association.* The problems of therapy were described by Crile who categorized early referrals to his clinic as follows: "Cases with wide-spread degenerations of most of the body, especially of the heart, brain, and liver. They included those emaciated to a skin and bone outline of their former selves; those whose heart spread out flabbily occupying much of the thorax; those with wide-spread edema; those with high fever; those delirious who had to be restrained in bed; those with partial dementia. Certainly, desperate risks; but I argued that if hypersecretion isn't the primary and essential cause of the disease, it was sound reason for thyroidectomy as for other urgent means."[7]

Prior to and even subsequent to the introduction of the preoperative use of Lugol's solution, many innovative means were utilized in attempts to eliminate mortality rate.

Resection of Cervical Sympathetic Ganglia

Removal of the upper and middle cervical ganglia had been advocated by Abadie and Edwards and popularized by Jonnesco and Jaboulay. In 1896 Souchon said, "these symptoms (the symptoms of exophthalmic goiter) are due to changes in the upper and middle ganglions of the sympathetic."[3] He was referring to the theory that exophthalmic goiter was not primarily a disease of the thyroid gland, but a central disease, located in the medulla with its morbid impulses coming through the sympathetic nervous system to produce an excess secretion of the thyroid gland. Mayo argued that cervical sympathetic resection was not as effective as an "operation upon the diseased organ itself."[4] Discussors Carr and Horsley agreed that cervical sympathectomy should be assigned to history and that evidence suggested that the unknown etiology of hyperthyroidism probably resided, as Mayo suggested, in the thyroid gland.

Operative Staging

Operative staging, in which lobar and isthmus resection were preceded by arterial ligation, were described by Kocher and popularized by Mayo. Bartlett,[8] however, must claim the record in the graduated approach to the removal of thyroid tissue in that he had subjected at least one patient to as many as seven operative procedures before the ideal had been accomplished. Those procedures and their temporal sequences were as follows: (1) ligation of the right superior thyroid vessels; (2) ligation of the left superior thyroid vessels five days later; (3) 12 weeks later creation of flaps and muscle dissection and insertion of a pack exposing the right thyroid lobe; (4) 2 days later removal of the right lobe; (5) skin closure 2 days later; (6) 7 months later, left lobe removal; and (7) skin was closure in 48 hours. Further, he stated, "Of course we have frequently ligated both superior thyroids at one sitting and removed both lobes at another hence it will be seen that the graduated approach with us has meant two, three, four, or even more operative stages up to the limit of seven, which is admitted to be the practicable limit."[8]

Roentgen Ray Therapy

Roentgen ray therapy first was mentioned by Mayo in 1905[4] and again in 1906[5] when he described 300 goiter operations, of which 110 were for exophthalmic goiter. In that presentation, Mayo said, "Patients who are not advised to have immediate operation are often kept under observation for weeks until we are satisfied of their ability to withstand surgical treatment. Aside from rest, internal treatment consists of extract of Belladonna, ⅙ grain, with quinine in pill form given three or four times a day. If no improvement is noted, we use x-ray exposure to the extent of skin irritation."[5]

In 1909 Deaver recommended rest and quiet before operation, "It is now evident that x-rays have no specific action in controlling the disease."[9] Richardson in 1922, however, advocated the use of x-ray therapy only for patients with toxic diffuse disease and not for those with "adenomatous goiter with hyperthyroidism".[10] In therapy and its evaluation, he stressed the "availability of adequate, modern, roentgen-ray equipment with the ability to measure dosage" and the use of basal metabolic rate to determine the degree of benefit.[10] Richardson concluded that subtotal thyroidectomy was a more effective form of treatment than x-ray therapy, that roentgen ray had a beneficial effect on certain cases of hyperthyroidism, and that the effect of x-ray was not sufficiently constant to be relied upon as a form of therapy.[10] He mentioned the problem of occasional myxedema and the increased degrees of technical difficulty following the use of x-ray but advocated continued use and study of the modality stating, "In selected cases of exophthalmic goiter, the use of roentgen-ray treatment under careful control was justified for a period of four months during which the patient received about five treatments and finally if after four months of treatment, the degree of improvement in general condition and basal metabolic rate does not promise cure, operation should be undertaken."[10] In discussion, W. H. Wathen believed that, in his experience with over 1000 cases, roentgen ray use was pernicious and had made the technical aspects of the operation much more difficult. He continued to favor preliminary arterial ligation. Mayo agreed and said that although he had in earlier works discussed the use of x-ray therapy in the temporary control of patients with hyperthyroidism, he no longer was an advocate and stated, "If however, they are subjected to three or four months roentgen-ray treatment and then require surgery, I would rather be away from home when they come."[10]

Anoci Association

At the 1912 meeting, George W. Crile urged the exclusion of the patient from psychic stress. Noting that removal of the patient from a stressful environment did not completely eliminate postoperative storm and citing two deaths "from fear of the operation alone,"[11] Crile championed a method of blunting of association impulses by introducing a system of anesthesia designed to minimize the effect of surgical shock. The patient's mind was calmed by the injection of scopolamine and morphine 1 hour before operation. General anesthesia was supplemented by the injection of procaine, which preceded the division of sensitive tissues. Sharp dissection and gentle manipulation were employed, and to minimize postoperative discomfort in serious cases, quinine and urea hydrochloride solution were injected at some distance from the wound. The concept of "stealing" the toxic thyroid was also a Crile innovation.[11]

Injection of Boiling Water

This method of preoperative control was first mentioned as a possibility by Porter before the Southern Surgical Association (SSA) in his discussion of Mayo's paper in 1908.[6] Ten years later, Porter stated, "For the preparation of the substandard risks for major operation, injection of boiling water into the gland substances is more effectual than any other known procedure. In quite a percentage of patients with small goiter of the diffuse hyperplastic variety, injections of boiling water should be the treatment of choice in that it is efficacious and entails less risk and less loss of time than any other method of treatment."[12]

Although Porter utilized the method several hundred times, the first recorded use of boiling water in the *Trans South Surg Assoc* was accomplished by Carr. In discussing Crile's paper concerning psychic stimuli, Carr intimated that he had combined the techniques of anoci association and the use of boiling water. He stated that in a patient with hyperthyroidism and a fibroid uterine tumor, he had operated upon the woman for removal of the fibroid without her knowing that anything was going to be done to the thyroid gland. After removal of the tumor, "I injected the gland with boiling water as suggested by one of our members, while she was under the nitrous oxide anesthesia. She came off the table with a pulse of 80, which had never been under 100 for a year . . . It never went up anymore, and she has been perfectly well ever since."[11]

The introduction of iodine in the preparation of patients for surgical resection of toxic goiter occurred in 1922. McClure in 1926 mentioned for the first time in *Trans South Surg Assoc* the preoperative use of iodine as follows: "The revival of the use of iodine in the treatment of goiter—a treatment as old as the history of medicine—has added much to the success of the operative treatment of Graves' disease as well as in diminishing the amount of colloid goiter."[13]

Sistrunk reported that the preoperative preparation with iodine had dramatically decreased the need for staging.[14] In 1927 1520 patients were operated upon at the Mayo Clinic for exophthalmic goiter and ligations were done in only nine patients; Sistrunk reported further that no ligation had been performed for that disease in the 1928 series.[14] He cited a reduction in the mortality rate to 0.72% and a mortality rate of 0% in those patients operated upon within the first 6 months to 1 year following onset of their disease. He also noted a reduction in morbidity rate, a saving of time and expense with patients because only 8 days to 2 weeks of preparation were required, a diminution of recurrence, and a decrease in the technical difficulties of operation.[14] Sistrunk and Crile agreed in discussion that the use of iodine was the greatest single advance in the treatment of hyperthyroidism and that iodine in many instances was being improperly utilized. The advice given was that if iodine was given for periods longer than 8 days to 2 weeks, the disease seemed to progress to a more active stage, the thyroid became refractory to iodine use with gland enlargement, the metabolic rate and severity of symptoms increased, and the degree of operative risk was accelerated.

The next problem addressed in *Trans South Surg Assoc* relates to the amount of residual thyroid tissue to be left at the time of subtotal resection. The first formal paper on subtotal resection was presented by Bartlett 1916.[15] Bartlett described leaving a residium on each side of the trachea "frequently not larger than a pecan nut, varying, of course, with the original size of the tumor and the character of the material at hand."[15] In the discussion of Bartlett's paper, Finney said that for many years he had been a "heretic in the matter of orthodox ideas and practices and treatment of hyperthyroidism" and had in the preceding 5 years done subtotal thyroidectomies in about 50 patients.[15]

The amount of gland to be resected was stabilized at the Mayo Clinic (circa 1917) and resulted in the then current practice of leaving an amount of thyroid tissue on either side of the trachea that was equivalent to "one-sixth to two-thirds the amount of tissue in a lobe of normal size."[16] That policy, he said had resulted in a significant reduction of recurrences. Furthermore, he stated that the facts (with respect to recurrence rates) did not support extension of the conservative subtotal thyroidectomy and that any such assumption wholly disregarded the fact that recurrences may be secondary to a stimulus or stimuli, that originally caused the disease.

In 1931, Lahey stated that a guide to the amount of residual thyroid remaining following operation related to the degree of involution that did or did not occur in response to preoperative iodine therapy.[17] He referred to a study by Cattel, which showed that involutional response to iodine was evident in 90% and absent in 10% of those treated. Further, he said that iodine involution or noninvolution usually did not occur without clinical evidence of its existence or without gross macroscopic evidence of its presence when a cross section of the gland was made at the operating table.[17] In general, Lahey advised that larger remnants should be left in those who had involuted glands.[17]

In 1930 Lahey called attention to an unusual group of patients who were middle aged or older, who tended to have no exophthalmus, with small thyroid glands, with pulses in the range of 100 to 120 that were neither full nor bounding, with cardiac apex beats that were not forceful, with general motor movements characterized by "definite repose" approaching apathy, and with dry cool skin, an exaggerated appearance of aging, and a lower metabolic rates than that seen in younger patients.[18] Lahey coined the term "apathetic thyroidism" to characterize this panel of patients.[18] He stated that a characteristic of this disease was the fact that it remained undiagnosed for long periods of time and that the unrecognized general deterioration of organ systems was such that these patients had exceedingly high potential for postoperative mortality rates. Thus, he advised that these patients have a two-stage operation for cure, namely, removal of lobes at separate operations 6 weeks apart.[18]

The two-stage operation continued to be utilized also by Lahey in selected thyrocardiac patients.[19] Of 303 patients described, 262 had auricular fibrillation and 41 had normal rhythms but with varying degrees of cardiac failure. Of those with fibrillations, 175 also had "clear congestive heart failure."[19] Lahey advised, "We have repeatedly written on the subject of thyrocardiacs and have presented evidence to prove that patients in seemingly hopeless stages of decompensation can by subtotal thyroidectomy not only have their compensation restored but themselves be rehabilitated to a degree that permits normal activity in most cases."[19] Preoperative preparation was nutritional via diet and glucose, digitalis (for arrhythmia), and Lugol's solution. In a 1933 follow-up study of those 303 patients, fibrillation was restored to sinus rhythm and remained normal in 71.5% and compensation resulted and persisted in at least 95%. The mortality rate was 4.25%.

A natural extension of those good results on thyrocardiacs was a trial of thyroidectomy for patients with congestive failure and with angina who were not afflicted with hyperthyroidism. Thus, Parsons and Parks[20] related their own experiences and those of others gathered via a survey of members of the American, Southern, and Western Surgical Associations who had performed total thyroidectomies for those entities. Data were gathered on 362 patients.[20] Of the 229 patients with cardiac failure, there were 24 operative deaths.[20] The mortality rate in 133 patients with angina was 3.5%.[20] The authors were encouraged by the reported improvement of patients surveyed in spite of wide divergence of opinion by others with respect to the value of the procedure.

Lahey's comments based on personal experience and upon the accumulated reports was less enthusiastic.

> "The number of good results in this series, is in our opinion, not sufficient to make us entirely pleased with them. I do not believe that this operation will endure as a much practiced procedure for the following reasons: First of all, any patients who are operated upon for cardiac decompensation by total thyroidectomy have, of necessity, a very limited cardiac reserve; secondly, one must produce a myxedema, and it is accepted that myxedema is an undesirable state for a decompensated heart. Therefore, it is said that these patients should be given thyroid extract until they are maintained at approximately a minus 25 metabolism . . . this is too complicated a position to maintain with any degree of accuracy, and in the majority of cases . . . they have had a return of decompensation or have died. In the cases of angina pectoris, there have been a few cases who have been distinctively benefited and if a patient is willing to exchange an active state for the sluggish state associated with myxedema, there are undoubtedly certain cases in which the anginal pain can be modified."[20]

In 1938 Laymann and Shearburn,[21] in a well-designed scientific study, were unable to find any quantitative relationship in the duration of preoperative treatment with iodine and the patient's postoperative course, the level of the initial basal metabolic rate, and the patient's postoperative course, or the level of the initial basal metabolic rate and the duration of preoperative iodine treatment.

Cole[22] deprecated the employment of thyroidectomy on patients with neurocirculatory asthenia and pointed out that the differential diagnosis could be made by noting the patient's response or lack of it to iodine therapy. He stressed insulin control of the diabetic patient prior to surgery for hyperthyroidism and noted that insulin requirements in the postoperative period were not infrequently decreased.[22] Cole's was the first mention of negative calcium balance in the hyperthyroid patient, and he advocated the preoperative use of calcium; Cole thought that there were some occasions on which intratracheal anesthesia should be administered, particularly in those with a significant degree of tracheal obstruction, but he was concerned about the surgeon's inability to detect recurrent laryngeal nerve injury during its use.[22]

The issue of staging operations had not suffered its complete demise in 1940, and both Cole[22] and Lahey[23] defended the use of staging in selected patients. By 1940 Lahey had developed a criterion, based on observation of increased oxygen consumption during operation, as a determinant for ending the procedure at the completion of a subtotal lobectomy; he also used a rising pulse rate and increased anesthetic requirement as indications for staging.[23]

In 1946 Lahey reported upon the use of thiouracil, thiobarbital, and propylthiouracil in the treatment of thyrotoxicosis.[24] He had, in the three and one-half years prior to his report, prepared 660 patients with various types of hyperthyroidism and in addition had employed the antithyroid drugs in 21 patients over a lengthy time span to determine whether the medications could be used as a substitute for resection. Lahey stated that all three of the agents were equally effective in reducing the basal metabolic rate, but that of the three agents, propylthiouracil was by far the safest, especially with respect to bone marrow depression.[24] The surgical disadvantages of the thiourea drugs resided in the fact that when patients were prepared solely with one of the drugs, hyperplasia increased, as did the vascularity of the gland, and operating conditions were virtually impossible. Lahey indicated that all the advantages of operating upon a patient freed from toxicity were more than offset by the difficulties encountered (friability of the gland, uncontrollable bleeding and inability to obtain satisfactory anatomic exposure).[24] Omission of propylthiouracil during the final preoperative week and administration of iodine for 3 weeks prior to operation eliminated those disadvantages in Lahey's experience. All eight of Lahey's patients who were pregnant tolerated the drug well, underwent thyroidectomies without indicident, and completed their pregnancies and delivery of healthy babies.[24] Twenty-six patients with diabetes improved, some becoming latent and others requiring less insulin. Of the 21 patients treated for as long as 20 months prior to withdrawal of the drugs, eight had remained in remission and 13 had relapsed at the time of his report. Lahey proposed that permanent cure was not to be expected from the administration of antithyroid drugs alone.

In 1959, Byrd et al.[25] evaluated the results of three modalities of therapy for hyperthyroidism; the use of thiourea derivitives alone, subtotal thyroidectomy following preparation with thiourea derivatives and iodine, and radioactive iodine therapy. There were 100 patients in each group. They concluded that (1) therapy should be individualized and only an occasional patient could be managed with thiourea drugs alone; (2) people with concomitant disease were candidates for therapy with radioactive iodine and/or antithyroid drugs; (3) the use of radioactive iodine was indicated in the rare patient with postresection toxicity; (4) the incidence of hypothyroidism was less after resection than following radioactive iodine therapy; and (5) the evidence justified the continued use of surgery as the basic procedure of choice in the management of the otherwise uncomplicated thyrotoxic patient.[25]

The sole reference to treatment of thyrotoxicosis in children was addressed in 1977 by Hothem et al.[26] in their experiences in managing that disease in 105 patients between the ages of 3 and 18 years.[26] All patients were initially treated with antithyroid drugs. Twenty-six per cent achieved remission on that regimen. Sixty-eight per cent were treated by subtotal thyroidectomy with three patients requiring subsequent therapy with radioiodine. Six per cent were treated with radioiodine with one of those subsequently requiring operative intervention.[26] In the decade prior to their report, there was earlier selection for operation as dictated by their experience. Ninty-one per cent of the males, 89% of children over 11 years of age, and all patients who had no regression of thyromegaly after a sustained period of control received operation or radioiodine therapy. Recognition of the discriminants of age, sex, and failure of regression of thyromegaly, they stated, would permit earlier selection for suitable therapy.[26] Hothem et al.[26] concluded that subtotal thyroidectomy in children had a low morbidity rate and was an effective treatment for thyrotoxicosis in that age group.

The preoperative preparation of patients with thyrotoxicosis took a quantum leap to comtemporary times with the reports by Lee et al.[27,28] relating the use of propranolol. The initial report delivered to the SSA in 1972 related the experience with 20 patients.[27] By 1981 a total of 160 patients prepared with propranolol alone formed the basis of the study and presentation.[28] Lee et al. reported that the beta-adrenergic blocking agent effectively neutralized symptoms of autonomic hyperactivity without significantly affecting thyroid function or levels of thyroxine.[28] The latter observation dictated the postoperative use of propranolol in decreasing doses for 1 week. There were no postoperative cases of storm nor was there any report of morbidity or mortality rates. Thomas and van Heerden in discussion agreed with Lee et al. in general but cautioned that propranolol should not be used in patients with antibodies to beta-adrenergic receptors (*e.g.*, in patients with allergic asthma or with cystic fibrosis).[28] Further, certain patients (a low percentage) did not respond to beta-adrenergic blockade (Thomas). Van Heerden pointed out that there was a synergistic effect when propranolol and iodine were used in combination affecting a greater reduction in T-4 than could be obtained with either alone and said that a combination of Lugol's solution and propranolol was being used at the Mayo Clinic for preoperative preparation. Thomas believed that the fact that patients could be prepared with propranolol alone did not necessarily mean that this was a method of choice for all patients or for all surgeons, and favored a more conventional approach with antithyroid drugs and iodine. Propranolol and iodine were suggested by Thomas for those patients who were intolerant of thioamide drugs.

This record is a brief historical summary of the contributions and courage of those in the lineage of the Southern Surgical Association who, through vision, trial and error, dedication, tenacity, and application of scientific principles, have enabled mankind to conquer a fatal disease, thyrotoxicosis.

Development of Current Concepts for the Treatment of Breast Diseases as Documented by the Transactions of the Southern Surgical Association

EDWARD M. COPELAND III, M.D.* and KIRBY I. BLAND, M.D.†

From the Department of Surgery, University of Florida College of Medicine, Gainesville, Florida

THE FIRST SCIENTIFIC MEETING of the Southern Surgical Association (SSA) was held in 1888, and all papers presented at this and subsequent meetings were published in the annual bound volumes of *Transactions of the Southern Surgical Association.* In the early years of the SSA, many of the articles published were papers that were read by title and not actually presented or discussed.

Throughout the 19th and early 20th centuries, the prognosis for breast cancer was dismal because of the advanced stage of the disease at the time of initial presentation. Diagnosis was made by clinical examination, and mastectomy was done without prior biopsy confirmation of invasive disease. Breast cancer was not a very popular topic for presentation at the scientific sessions of the SSA, as evidenced by the paucity of papers on the subject during the first quarter century.

It was not until the fourth meeting in 1891 that breast cancer was the subject of a published manuscript. Tiffany[1] identified the differing clinical behavior between lesions that produce skin edema and those that are only attached to the skin. Also, Tiffany accurately defined Cooper's ligaments, although he did not use the term. He pointed out that skin dimpling by scirrhous carcinoma was a consequence of entrapment of these "fibrous" bands within the malignant process.[1]

The first actual presentation on the subject of breast cancer was delivered at the sixth meeting in 1893 by Gaston,[2] who described cachexia that developed with progressive cancer growth. He questioned the rationale of doing an axillary dissection if lymph nodes were involved clinically because chest wall recurrence in such circumstances was 75% in his series. In the discussion that followed, Westmoreland stated an opposing view. He believed that the recurrence rate would be 90% in the axilla if lymph nodes were not removed, and he considered the axillary component of the mastectomy so important that he would do a secondary operation to remove axillary lymph nodes if a patient was sent to him having had only a total mastectomy. Westmoreland also described Rotter's nodes as a potential source of recurrence in a patient who had not had a radical mastectomy.

The report of Gaston contained the results of an interesting questionnaire in the form of a circular letter sent out that same year by Shumway. The operative mortality rate from a radical mastectomy ranged from 10% to 23% (Billroth reporting 23%); the average increase in life expectancy from the operation was estimated at 12 months; and the 3-year cure rates ranged between 9% to 25%. There were no reports of spontaneous cures of breast cancer.

In 1894 Evans[3] reported a single case of simultaneous appearance of breast and uterus cancer. During the same year Halsted[4] and Meyer[5] each published independently and for the first time a description of the procedure of radical mastectomy. Neither Halsted nor Meyer was a member of the SSA.

Because most cancers resected during the 1890s were bulky lesions, wounds were often left open to granulate if skin coverage could not be obtained. Nevertheless, members of the SSA were interested in attempting to improve both the functional and cosmetic result following the treatment of breast cancer. In 1894 Wilson[6] ad-

vocated coverage of the wound with a split-thickness skin graft, both to impede local recurrence and to improve patient comfort.

Surprisingly, in the 12 meetings of the SSA that were held during the 19th century, only three papers dealing specifically with breast cancer were actually presented, while two more on the subject were read by title. Even more surprising is the fact that in the 10 years that followed, comprising the first decade of the 20th century, not a single paper dealing specifically with breast cancer was presented. It was not until 1910 that the subject of breast cancer was again brought to the attention of the membership. In discussing factors that influence the prognosis of cancer operations, Crile[7] stated that he had cured no patients with breast cancer who had metastasis to the apical axillary lymph nodes. In those individuals in whom the disease was limited to glandular tissue, however, 80% remained alive for a 3-year interval. He considered the most important single factor in the treatment of breast cancer to be early detection prior to the involvement of axillary lymph nodes.[7]

Judd[8] in 1913 reported that breast cancer can recur much later than the customary 3-year interval. Likewise, he argued against the removal of lymph nodes above the clavicle, pointing out that disease in this location represented distant metastasis. His report of 607 patients also dispelled the contemporary theory of the era that breast cancer in young women was uniformly lethal.[8] Table 1 depicts the follow-up study of his patients from 2 to 11 years. Judd described several patients who had a delayed radical mastectomy following biopsy diagnosis and who appeared to have a prognosis equally as good as did those individuals who had an immediate operation.

Chronic cystic mastitis and multiple fibroadenomata presented confusing diagnostic and therapeutic dilemmas to surgeons in the late 19th and early 20th centuries. In 1897 Tiffany[9] described 11 women in their mid-40s who had typical fibrocystic disease and in whom he did total mastectomies. In his opinion, cystic fibroadenoma was either a malignant or premalignant condition, and total mastectomy was necessary to prevent recurrence of the disease.[9] Tiffany thought that a possible etiology of cystic fibroadenoma was the use of suction cups by young women, a practice in vogue at the time, to enlarge the size of the breast.[9]

In 1893 König[10] coined the term "chronic cystic mastitis." He chose the term because he considered this pathologic process to occur secondary to a "vicious cycle of secretion and irritation."[10] In 1910 MacCarty[11] first used the term "chronic cystic mastitis" but noted that some cells did penetrate the basement membrane. He considered these cells to represent invasive breast cancer at its earliest stage and recommended radical mastectomy as the treatment of choice.[11] MacCarty expanded his report before the SSA in 1913.[12] He identified primary, secondary, and tertiary ductal hyperplasia and recommended simple excision for primary hyperplasia and radical mastectomy for the tertiary variant. For women under 35 years of age, he recommended a total mastectomy for secondary hyperplasia for both diagnosis and treatment. For older women, he recommended a partial mastectomy for diagnosis and, when tertiary hyperplasia was identified in the specimen, a radical mastectomy was considered appropriate therapy.

TABLE 1. *End Results: 514 Determinant Cases*[8]

	% Survival (2–11 years)
Dead of other causes	4.1
Alive with breast cancer	7.3
Dead of breast cancer	47.6
Alive and well	41.0

Thus, as early as 1910, pathologists had identified *in situ* breast cancer and had predicted a spectrum of morphologic changes in ductal cells that ranged from atypical hyperplasia to invasive breast cancer. During this era, both surgeons and pathologists realized that early diagnosis was essential to ensure survival for patients with breast cancer. Nevertheless, MacCarty, for the first time at the SSA, questioned the advisability of completing a total mastectomy for apparent benign conditions such as primary hyperplasia.

In 1920 Bloodgood[13] catalogued the differential diagnoses of 350 benign operative specimens (Table 2). Bloodgood appropriately indicated that chronic cystic mastitis was not a precancerous lesion and, therefore, did not require mastectomy. The entire breast was available for examination in 222 of the 350 specimens. Obviously total mastectomies had been done. There was no gross or microscopic evidence of cancer in any of these specimens. Bloodgood did, however, continue to make the diagnosis of cancer on clinical grounds alone and was willing to recommend a mastectomy solely by this mechanism. His clinical diagnostic criteria for identifi-

cation of benign disease were as follows: (1) a patient less than 25 years old; (2) tumor present 2 years or longer without growth; (3) multiple tumors—particularly in both breasts; (4) single definite nodule associated with indefinite nodules; and (5) no definite tumor but multiple indefinite nodules. Further, he would recommend radical mastectomy if microscopic examination of the tissues in any of these clinical presentations was doubtful.

In 1921 the treatment philosophies espoused by Bloodgood were echoed by others. Peck of New York in discussion of Bloodgood's second presentation[14] before the SSA emphasized that "there is no excuse for doing a radical operation for benign lesions if reasonable care is taken in making a diagnosis, local removal of the mass being quite sufficient." Also, in discussion of Bloodgood's presentation, Finney commented on the success of educational programs to alert women to the early diagnosis of breast cancer. He found that the diagnosis of breast cancer was becoming more difficult because women were reporting to his office with "imaginary tumors." Early in his career, he pointed out, diagnosis of breast cancer was easy to make clinically because women reported initially with advanced stages of disease. Such a situation in 1920 was no longer the case.

In 1928 Deaver[15] challenged the precancerous nature of any benign condition and strongly stated that mastectomy should not be done, especially in young women, until cancer was proven by microscopic section. He recommended that biopsy be done with a small rim of normal tissue, and that the surgeon change gloves before closing the wound to prevent implantation of healthy tissues with cancer cells. Deaver reported an 8-year follow-up study of 242 patients operated upon with benign conditions in whom no malignancy had developed.[15]

By the mid-1920s, radiation therapy either before or after operation was becoming popularized and advocated in European and American clinics. In 1926 Ochsner[16] condemned x-ray therapy; he considered it to be of little value and potentially harmful because of the morbidity of local complications. Deaver[15] postulated in 1928 that radiation therapy may cause lymphedema of the arm, but he also had seen treatment with radiation therapy cure arm lymphedema when it was secondary to recurrent cancer in the axilla. In 1928 Crile[17] supported the use of postoperative radiation therapy. His disease-free survival for 4 years with and without radiation therapy was 25.9% and 24% respectively. These data did not convince the SSA membership, and in 1931, in a discussion of a presentation by McClure,[18] Trout, a previous advocate of radiation therapy, indicated that he could find no objective evidence that survival had been increased by the use of this adjuvant therapy. Likewise, he was surprised to find that throughout the United States some radiotherapy machines were improperly calibrated and were causing chest wall burns.

Lee made several important contributions to the understanding of the biology of breast cancer. In presentations before the SSA in both 1929[19] and 1932,[20] he pointed out the influence of axillary metastasis on prognosis. The overall 5-year survival rate of his patients was 41%. Patients with positive axillary lymph nodes had a 5-year survival of 23% *versus* 72% in those with negative nodes. The quadrant of the breast in which the breast cancer arose had no influence on survival. He noted that in the immediate past, surgeons had been operating upon virtually all stages of breast cancer and believed that the more advanced forms should be treated by a combination of palliative surgery and local irradiation. He defined inoperability as fixation to the chest wall, multiple cutaneous nodules, extensive axillary metastases with a swollen arm, positive supraclavicular lymph nodes, and distant metastases. McClure[18] and Nicolson[21] presented data substantiating the results reported by Lee. In multiple presentations by different authors before the SSA for many years to follow, Lee's criteria of inoperability were applied to define their populations.

The etiology of breast cancer had been discussed by several authors. In 1913 Bryan[22] expressed the idea that trauma was responsible for 13% of female mammary cancer and for 50% of male cancer. In 1933 Trout[23] was a proponent of the lymph stasis theory because many women with carcinoma of the breast had a history of some dysfunction affecting the breast, such as irregularity of lactation, abscesses, definite trauma, infected nipple, *etc.* He pointed out that the incidence of carcinoma of the breast in Chinese women was much higher than any other race and likewise noted that a flat chest in this race was regarded as a very prized possession. Trout suggested that binders on the breasts of Chinese women might produce trauma and stagnation. In 1933 Bullock[24] thought that closely fitted clothing might increase lymphatic stagnation in the breast, and Adair[24] described a laboratory experiment in which ligation of the terminal ducts of the nipple in mice increased the incidence of spontaneous mammary cancer from 5% to 87%. He was convinced that the advice given to mothers by obstetricians to avoid nursing and subsequent lactation was incorrect, as resultant stagnation of milk within the ducts was a major contributor to the etiology of mammary cancer. In 1935 Nicolson and Berman reported that the lactating breast was less likely to develop carcinoma than a nulliparous breast.[25] The largest per cent of breast cancers in their series occurred in the upper outer quadrants, possibly explained, in their opinion, by the imperfect lymphatic drainage in this portion of the gland due, in turn, to poor support of the breast. The authors felt that the proper type of brassiere, supporting but not constricting, would reduce breast lesions and would consequently lower the incidence of malignancy. In 1937 Cohn[26] retrospectively compared the indigent white and black populations at Charity Hospital to identify any epidemiologic or possible etiologic differences. Long-term survival data were not available, but there was no difference in the clinical behavior or natural history of the disease based on race alone.[26]

In 1934 Rodman[27] defined the morphologic changes that occur in chronic cystic mastitis. He correlated these changes with the menstrual cycle, thereby identifying the alteration in hormonal milieu as etiologic in this benign disease. He recommended local excision for adenofibromas. For patients with chronic cystic mastitis under the age of 35, a breast mass was observed through two menstrual cycles, and if it did not change appreciably, it was then removed by excisional biopsy for microscopic study. For women over 35 years of age, and in whom the mass did not change appreciably, amputation of the breast with pathologic examination of the whole specimen was recommended as it had been in the past. If breast cancer was identified, then a radical operation was completed.

In 1943 Cole and Rossiter[28] classified chronic cystic mastitis into four types (Table 3). They pointed out that two or more of the four types were often encountered in a single biopsy specimen. Precancerous hyperplasia was often seen in close proximity to frank, invasive breast cancer, and cancer often developed in breasts known to harbor precancerous hyperplasia identified by a previous biopsy. Cole and Rossiter doubted the validity of frozen section diagnosis for precancerous hyperplasia and, although the resemblance to cancer at times was remarkable, they did not think that a diagnosis of cancer was justified without the pathologic criterion of invasion.[28] Cole summed up their thoughts as follows: "If you cannot be sure about the diagnosis, and fear cancer, the breast should be removed or a very wide excision done."[28] They urged, however, to improve diagnostic ability so that every nodule of the breast did not need removal.

TABLE 3. *Chronic Cystic Mastitis: Classification*[28]

1. Adenofibrosis
2. Benign parenchymatous hyperplasia; no atypical change
3. Precancerous hyperplasia; advanced proliferation of cells with layering and increased mitoses; no invasion
4. Cystic disease; no epithelial hyperplasia

In 1939 Brooks and Daniel[29] presented the status of radical mastectomy at Vanderbilt. The Halsted radical mastectomy was beginning to be questioned by other authors. In Britain, some surgeons were performing a simple mastectomy or lumpectomy alone. Only 33% of patients with positive lymph nodes in the Vanderbilt series survived. Nevertheless, the authors concluded that "these patients could not have been cured of the disease by simple mastectomy and all of [our] experience has been contrary to the view that as good survival periods could have been obtained by the employment only of conservative operations."[29] Marshall and Hare[30] condemned the use of the simple mastectomy alone as treatment for carcinoma of the breast, noting that patients with extensive axillary involvement could be salvaged by radical mastectomy, particularly when combined with appropriate roentgen ray therapy. Trout[31] likewise reported both his and his father's patient series from 1909 until 1950. He noted that from 1909 to 1920 there were 152 patients in whom the 5-year survival rate was 22%. From 1924 to 1928 there were 86 patients, and during this time roentgen ray therapy was added. The 5-year survival rate increased to 55%. In the most recent series of 195 patients, 5-year survival rate was 81% for patients with negative axillary lymph nodes and 40% for patients with positive lymph nodes. Thus, enthusiasm for adjuvant radiation therapy was rekindled.

In the early 1950s modern concepts emerged for the management of benign and malignant breast diseases. Between 1946 and 1952, Harrington[31-33] presented the long-term follow-up data for over 6000 patients treated by radical mastectomy at the Mayo Clinic (Table 4). These reports emphasized that breast cancer will recur throughout the lifetime of the patient and gave credibility to the concept that the most common cause of death in a patient with breast cancer between 5 and 10 years following diagnosis is, in fact, from metastatic breast cancer. This large study reconfirmed that the most important prognostic indicator was the presence or absence of axillary nodal metastasis. The degree of anaplasia and age at diagnosis were also considered important. For example, elderly patients with high-grade lesions had a better prognosis when compared to younger patients with an equal degree of anaplasia in the primary malignancy. In 1952 Goode and Martin[34] made several important observations. The first symptom in 44% of their patients was pain. The authors pointed out the obvious error of considering benign lesions painful and malig-

II	Small axillary nodes	43.8
III	Multiple axillary nodes	29.4
IV	Distant metastasis	1 of 5 patients

nant lesions insensitive as an all-or-none phenomenon. Likewise, when the surgeon and pathologist were in doubt about the frozen section diagnosis, these investigators considered it far wiser to close the wound and wait for permanent sections than to proceed with a simple mastectomy. Goode and Martin noted no appreciable effect on the 5-year survival with a delay of 48 hours to await permanent section in inconclusive situations.[34] Postoperative roentgen ray therapy did not appreciably enhance the 5-year survival rate for those patients who had positive axillary nodes. For the first time, a staging system was presented to the members of the SSA, reflecting those used currently (Table 5). The philosophical concept that breast cancer was a systemic disease and potentially unaffected by local treatment had arisen. Patients with untreated breast cancer had a 5-year survival rate of 22%, whereas the authors' overall 5-year survival rate was 64.4%. These data suggested that the surgeon does play a major role in the treatment of primary breast cancer and that delay in therapeutic intervention increased patient morbidity and mortality rates.

In 1952 Copeland,[35] in discussing Kerr's presentation, described the role of progesterone and estrogen in the stimulation of hypertrophy and hyperplasia of both duct and lobular cells. He concluded that an imbalance of these two hormones was reflected as chronic cystic mastitis. His recommendation, and that of Kerr,[35] was to aspirate large cysts, and if the fluid was clear and the cyst disappeared, no further therapy was necessary. Only 0.89% of cysts had an associated cancer.

In 1956 Alrich et al.[36] reported the results of radical mastectomy at the University of Virginia. The number of positive axillary lymph nodes and 5-year survival rate was the same regardless of the breast quadrant in which the cancer developed. The authors noted that simple mastectomy offered little more than palliation except in patients with early adenocarcinomas. In 1956 Byrd and Stephenson[37] reported on the experience with simple mastectomy for carcinoma of the breast at Vanderbilt. The original intent of the review was to identify the indications for simple mastectomy because the operation was used at Vanderbilt primarily for palliation. The authors found, however, that 23.7% of their patients had lived for 5 years or longer. Nineteen of 27 patients (70.4%) who had no metastasis at the time of operation lived for more than 5 years and only one developed a recurrence. Of the 102 patients with clinical metastases at the time of operation, 15.7% lived longer than 5 years. This report established that in certain circumstances simple mastectomy could achieve long-term survival in select patient subsets.

TABLE 6. *Comparison of Survival: Simple* vs. *Radical Operation*[38]

Three years	Radical (40)	Simple (56)
Overall survival	75%	80%
Disease-free survival	63%	71%
Four and one-half years	**Radical (27)**	**Simple (29)**
Overall survival	59%	69%
Disease-free survival	52%	66%

In 1960 Crile[38] reviewed the mounting world literature indicating that limited procedures followed by radiation therapy would result in similar 5-year survival rates for small breast cancers as would radical and ultraradical mastectomies. He emphasized that the medical profession should pay less attention to the possible involvement of lymph nodes by tumor and be more cognizant of the potential immunologic role that lymphocytes in these nodes play in the body's defense against cancer cells. In data from radical mastectomy specimens, Crile noted that 32% of patients with clinically negative axillae had histologically positive nodes, whereas only 22% of clinical Stage I patients, when treated by simple mastectomy and without radiation therapy, later developed clinically positive axillary nodes.[38] These patients were treated by a delayed axillary dissection. At the 3-year interval, disease-free survival was the same in both groups despite an average delay of 14 months between mastectomy and axillary dissection (Table 6).

A heated discussion was generated by Crile's paper.[38] Dumphy suggested that these patients were highly selected and praised Crile for his astute clinical judgement. He warned, however, that the data should not be accepted until a double-blind, randomized study was completed to evaluate the hypothesis. Criticisms by Firor were read by Blalock. Firor was critical of the small number of patients in each category, the short time of observation, and the heterogeneity of the two groups being compared. His most serious criticism was, however, "the immense harm that could result from an internationally famous surgeon's seeming to advocate an inadequate operation for the eradication of carcinoma of the breast."[38]

In 1959 Copeland and Higgins[39] addressed the diagnostic problem of nipple discharge. In patients between the ages of 20 and 49 years, discharge from benign lesions exceeded that from malignant ones by a ratio of 2:1. In the age group between 50 and 79 years, discharge from the nipple assumed an increasingly serious significance with the ratio being reversed in favor of malignant lesions. Bloody nipple discharge did not occur as a consequence of breast cancer in patients under the age of 30, and in those between 30 and 49 years of age, a bleeding nipple was most often associated with a benign condition. Bloody discharge in patients over 50 years of age, however, was associated with malignant disease in eight of 11 patients. McLaughlin et al.[40] noted a similar relationship between age and etiology of nipple discharge, and recommended a particularly aggressive approach to bloody nipple discharge in patients without a palpable mass who were over the age of 50 years. Simple mastectomy was considered justified to permit thorough examination of the breast. In the discussion, Bowen described a patient in whom the offending duct had been identified by cannulation with a probe immediately prior to exploring the subareolar area.

Sparkman[41] in 1961 explored the recent suggestion that false-positive frozen section diagnoses were leading to unnecessary radical mastectomies. Combining his experience, in which there were no false-positive diagnoses, with that of his colleagues in Dallas, the known incidence of unnecessary radical mastectomies per surgeon occurred once in every 167 years of practice. He concluded that frozen section remained a reliable diagnostic tool if the surgeon and pathologist were willing to defer an inconclusive result.[41]

For the remainder of the 1960s, several interesting papers were presented. Byrd et al.[42] updated the experience of the Vanderbilt Hospitals with a report of 1765 cases of breast cancer. Age had no effect on prognosis regardless of nodal status; the incidence of bilateral breast cancer was 2.5%. Horsley et al.[43] identified 67 patients, (4.3% of the Virginia series) with breast cancer who were 35 years of age or younger. The absolute 5- and 10-year survival rates were the same as the entire age spectrum of patients with this disease. All 12 pregnant patients survived 5 years. Byrd et al.[44] in 1961 reached the conclusion that pregnancy and lactation did not necessarily impart a poor prognosis for breast cancer. There was no maternal mortality, and one fetal death occurred in the 29 reported patients. Patients with positive axillary nodes had a 5-year survival of 28%, whereas all 11 patients with negative lymph nodes survived a minimum of 5 years.

In 1968 McLaughlin and Coe[45] updated their consecutive series and noted that the presence of one to three positive lymph nodes in the axillary specimen did not statistically alter survival when compared to patients with negative axillary nodes. Bilaterality of breast cancer was becoming of interest. In their series, 4.5% of the women developed bilateral breast cancer from 1 to 20 years after initial treatment.[45] In 1969 Finney et al.[46] reported an 8% incidence of bilateral breast cancer in a personal series. They also compared simple *versus* radical mastectomy. The cumulative probability of death from cancer in the two groups was similar for the first 10 years after operation, but after this time, the death rate in simple mastectomy patients increased remarkably above that for individuals having radical mastectomy. The authors concluded that patients with long life expectancy should be treated by radical mastectomy and that these results cast some doubt on the theory that lymph nodes within an intact axilla act as a defense against the spread of cancer.[46] Likewise, the authors pointed out that patients with four or more positive lymph nodes had a worse prognosis than those individuals with negative nodes or one to three positive nodes; yet, those patients alive after 5 years had the same probability of long-term survival regardless of lymph node status.[46]

In 1969 Amerson[47] reported seven adolescent females who had large lesions characterized by increased stromal cellularity and epithelial hyperplasia. The diagnoses were benign cystosarcoma phyllodes or giant fibroadenoma. This paper was important because it pointed out that adolescent females often have giant lesions in the breast that are benign, and that local excision maintains breast architecture without a recurrence. Nance et al.[48] reported 53 patients with Paget's disease of the breast. Sixty-one per cent of the patients had an underlying mass, and 40% had symptoms lasting longer than 1 year, usually secondary to a failure in diagnosis by the initial physician. All patients had at least a total mastectomy, and cancer was found in all but one specimen. Ninety-four per cent of the invasive carcinomas were within a palpable mass, and pagetoid change in the nipple was not a detrimental prognostic variable.

Madden et al.[49] presented their classic paper before the SSA in 1971. Ninety-three patients were reported who had neither pectoralis major nor minor muscles removed. Madden et al.[49] did not think removal of apical axillary nodes was valuable necessarily and identified no positive Rotter's lymph nodes in any of these dissected specimens. Also, lymphangiograms done before and after operation indicated that this operation removed all axillary contents. Five- and 10-year survival and local recurrence rates for the patients were similar to those for patients undergoing extended radical mastectomy. In 1978 Baker et al.[50] reported a comparison between modified radical mastectomy and radical mastectomy that revealed no statistically significant difference in 5-year survival for patients with Stages I, II, or III breast cancer. There was a significantly greater incidence of local recurrence in the axilla and mastectomy scar for Stage III patients treated by modified radical mastectomy. The authors postulated that the axillary nodal recurrences were secondary to inadequate dissection of the axilla, and recommended removal of the pectoralis minor muscle, apical axillary contents, and Rotter's nodes in patients with Stage III disease. In the discussion, Sanders emphasized that physicians who choose modified radical mastectomy make the decision subconsciously that the pectoralis major muscle and fascia are not involved. In a consecutive series of 105 patients who underwent radical mastectomy, he identified a 19% incidence of unsuspected involvement of the pectoralis major muscle and/or fascia by breast cancer.

After reports of the results from modified radical mastectomy[49,50] no further consecutive series of patients with operable lesions were reported before the SSA in an attempt to define the proper operation. The membership turned their attention to diagnostic tests, estrogen receptors, hormone manipulation, breast reconstruction, and the contralateral breast.

Preoperative Radiation Therapy

In 1939 Trout[51] reviewed the indications for preoperative radiation therapy. He included patients with large axillary nodes, lesions fixed to the skin, locally advanced disease that precluded surgical removal, and potential for carcinoma to be within a biopsy wound. For the first time before the SSA, an author concluded that proper radiation therapy to the chest wall aided radical surgery only in the prevention of local recurrence, and not in cures. In 1961 White et al.[52] reported a reduction in local recurrence rate following preoperative radiation therapy for locally advanced breast cancers. They proposed that residual disease after mastectomy was the most common cause for recurrence on the chest wall. The recurrence rate using their technique was only 5.2% compared to a 19.2% recurrence rate in individuals with similar lesions who did not receive preoperative radiation therapy. Townsend et al.[53] in 1984 reported 53 patients with locally advanced breast cancer who, likewise, had 4500–5000 rads of radiation therapy after operation. Eleven per cent of their patients developed chest wall recurrence. In discussion, Copeland presented two groups of patients; each had grave signs, but one group was technically suited for a total mastectomy and Level I lymph node dissection, whereas the second group was technically unsuitable but, nevertheless, had the same operation. Both groups received radiation therapy after operation. With a minimum 10-year follow-up evaluation, chest wall recurrences were 6% and 14% respectively, and the 10-year survival rates were 39% and 23% respectively, with no adjuvant chemotherapy. Copeland presented these data to indicate that control of chest wall disease in locally advanced breast cancer does result in, at least, some long-term survivors without the use of systemic chemotherapy. The most efficacious method of treating locally advanced breast cancer was with multiagent chemotherapy initially, followed by total mastectomy with Level I lymph node dissection, and then postoperative radiation therapy to the chest wall and supraclavicular, axillary and internal mammary lymph nodes.[53]

Hormonal Therapy

The treatment of carcinoma of the breast with estrogen was reported initially by Marshall and Hare.[30] They proposed that estrogenic compounds blocked the pituitary secretion of follicular stimulating hormone, thereby allowing tumor regression. In the same year, Horsley[32] reported a series of patients in whom he combined bilateral oophorectomy with radical mastectomy. Although the number of patients investigated was too small to be conclusive, he considered the survival results outstanding. In discussion, Lehman chastised Horsley for not presenting comparisons of cure rates in premenopausal patients with and without castration and for not correlating survival with extent of disease at the time of surgical treatment because it may have been more influential than castration on 5-year survival in this small series of patients.

In 1961 Horsley and Horsley[54] reported a series of 72 premenopausal patients who were treated by radical mastectomy and bilateral oophorectomy and followed for a 20-year period. Survival rates for patients with no axillary metastases were 91% at 5 years and 61% at 10 years. Those individuals with positive axillary nodes had a 5- and ten-year survival of 50% and 30%, respectively. Survival rates were comparable to women in the postmenopausal age group. Alrich and Hairston[55] reported a nonrandomized comparison of patients with and without oophorectomy treated at the University of Virginia (Table 7). When patients were stratified according to risk, prophylactic oophorectomy improved the overall survival by 10% and prolonged the disease-free interval in patients who subsequently relapsed.

In 1970 Horsley et al.[56] reported on 111 patients with skeletal and soft-tissue metastases treated by adrenalectomy. For those patients with a disease-free interval greater than 2 years, 68% responded, whereas those with an interval less than 2 years had only a 32% response rate. Fifty per cent of the responding patients were alive 2 years after adrenalectomy, whereas, only 24% of nonresponders survived 2 years. Adrenalectomy usually followed a prophylactic oophorectomy done at initial treatment of the primary disease. The authors concluded by recommending bilateral oophorectomy in the premenopausal patient with metastatic disease, and, if an objective response was obtained, then adrenalectomy was indicated after relapse. In the postmenopausal patient, adrenalectomy and oophorectomy were recommended at the time metastatic disease to bone or soft tissue was diagnosed. Horsley et al.[56] also found that the addition of 5-fluorouracil to their therapeutic regimen was beneficial. Multiple investigators confirmed these observations; in 1977 Wells et al.[57] reported the ability to medically suppress adrenal function with aminoglutethimide. Steroid suppression was reversible once aminoglutethimide was withdrawn. A previous response to hormonal therapy correlated with a higher incidence of complete or partial remission, an indication that estrogen receptor, a new technique at the time, might be predictive of response rates. In the discussion, Horsley said that he was using aminoglutethimide as a test mechanism to see which patients might respond to surgical adrenalectomy.

In 1952 Kerr[35] first reported the use of estrogen for the diagnosis of benign breast diseases. Oral estrogen frequently eliminated breast pain and was associated with softening or disappearance of breast masses. In only two of 575 patients, dissolution of various cystic disease masses left a single mass, which on biopsy proved to be malignant. A 2- to 20-year follow-up study did not reveal a single case of malignant disease following disappearance of a mass in response to estrogen therapy.

Byrd et al.[58] analyzed 713 patients who took an average daily dose of 1.25 mg of equine estrogen for 9 years or more. There was no increase in mammary cancer in this patient population and there was no increase in the death rate from breast cancer when it did occur. The patients, in general, enjoyed a much lower mortality rate overall than would be expected from the available population data, primarily from a decrease in mortality rates from all cancers, heart disease, and stroke. Byrd et al.[59] updated this review in 1976 with a report of 1116 patients followed between 5 and 28 years. New information suggested that women who had been receiving estrogen therapy and were nulliparous had a higher than predicted risk of developing breast cancer during the first 10 years of estrogen ingestion. Following this 10-year interval, however, the risk became similar to that of other patients from this study population. Gray and Hoover[60] in 1977 reported a follow-up study of 1891 patients who took oral conjugated estrogens. The overall risk for breast cancer was 1.3 times the general population, and it appeared that higher dosages of hormone therapy might result in an increased risk. There was a protective effect from multiparity and oophorectomy that disappeared after 10 years of therapy. A risk increase from nulliparity was not demonstrated in this study. The risk:benefit ratio favored the ingestion of estrogenic compounds in postmenopausal women without a substantial escalation in risk for the development of breast cancer.

Diagnosis

In 1972 McClow and Williams[61] compiled mammographic data from 3030 consecutive patients. Of 191 breast cancers identified in these patients, 35 (21%) were not palpable clinically, and 156 had symptoms and/or physical findings that would have initiated a biopsy in the absence of mammography. In this latter group, 11% of the cancers would have been missed by mammography alone. The authors concluded that for maximum diagnostic accuracy, both physical examination and mammographic criteria for biopsy are necessary.[61] In 1973 Shepard et al.[62] reported the diagnostic accuracy of mammography to be 80%. The rates of false-positive and false-negative diagnoses were 14% and 6%, respectively. Shepard distinguished between benign, large, dystrophic calcifications and fine stippled microcalcifications in localized areas that were characteristic of malignancy.

In 1985 Letton[63] reported a 100% follow-up study of 8058 women screened by mammography with a 10-year median duration of follow-up. Of the 912 women biopsied, 122 were found to have breast cancer. Thirteen had died by the time of the report. Eight cancers (6.6%) were found by clinical examination that were not detectable by mammogram. In 1986 Symmonds and Roberts[64] addressed the problem of diagnosis of nonpalpable breast abnormalities identified by mammogram. Needle localization was used for 499 breast biopsies. Seventy-two (14%) cancers were identified, 82% of which were invasive. Only 11% of these patients, however, had positive axillary nodes in comparison to the 63% incidence of positive nodes in occult lesions reported by McClow and Williams.[61] Suspicious calcification was the mammographic indication for biopsy in 184 patients. On only two occasions were the calcifications missed at the time of biopsy, and 20% of the biopsy specimens were malignant. These data are compared to results presented in 1982 by Powell et al.[65] who reported 251 consecutive patients with mammographic calcifications as a sole indication for biopsy. Forty-seven breast cancers were identified (19%), of which 36 (77%) were *in situ*. One of 11 invasive cancers had associated axillary nodal metastasis. Of the 106 patients who had a benign diagnosis, only four required subsequent biopsy for calcifications, all of which were benign. Thirty-seven biopsies (13%) would have been inadequate without the use of specimen radiography. Letton[63] also reported a 17% incidence of carcinoma in patients operated upon because of mammographic evidence of suspicious calcifications.

In an evaluation of 10,131 asymptomatic women in the Louisville Breast Cancer Detection Demonstration Project, Bland et al.[66] compiled an analysis in 1981 for 1759 histologic characteristics in biopsies of 863 patients with proliferative and nonproliferative fibrocystic disease. Xeromammography (XM) allowed recognition of ductal and lobular hyperplastic lesions, sclerosing adenosis, or epithelial cysts as the major constituents of 64–69% of the high-risk XM images. However, XM parenchymal patterns observed in these screenees incompletely correlated with known pathologic variables and risk factors. Consequently, the authors recommended clinical integration of risk factors with XM patterns to determine those patients who should be followed at frequent intervals.

In 1976 Baker[67] challenged the necessity of breast biopsies as an inpatient procedure. He reported on 153 consecutive biopsies done on outpatients under local anesthesia. Nineteen breast cancers were detected, and the patients were hospitalized within 1–3 days of biopsy for definitive treatment. Only one patient developed a small hematoma. The author emphasized that there was a tendency to limit the extent of the biopsy if the procedure was done under local anesthesia and that every effort should be made to excise a generous portion of normal breast tissue surrounding the palpable mass.[67] In 1983 Wanebo et al.[68] reported 100 patients on whom a definitive diagnosis was made by fine needle aspiration of a suspicious breast mass by use of a piston syringe with an attached 22-gauge needle. Seventy-one patients had mastectomy without frozen section confirmation of the diagnosis, and all had breast cancer. This presentation stimulated a heated discussion about the advisability of progressing to mastectomy with only fine needle aspiration cytology as the diagnostic criterion. Three SSA members, Zeppa, Newsome, and Horsley each reported one false-positive cytologic diagnosis from their institutions. The summary opinion was that specimens obtained by fine needle aspiration and read by an expert pathologist were satisfactory to progress to mastectomy, yet most surgeons managing breast diseases were not in a position to have the luxury of a pathologist with such expertise.

In 1930 Newsome et al.[69] evaluated the influence of time and sample procurement on estrogen receptor activity. Patients were treated by a modified radical mastectomy from 1 to 7 days after biopsy. Estrogen receptor activity was done both on the initial biopsy specimen and on tumor samples removed from evaluable patients at the time of mastectomy. Changes in estrogen receptor levels ranged between 15% and 100% with a mean decrease of 70% during the interval from biopsy to mastectomy The authors speculated that the decrease in receptor activity was secondary to necrosis, tumor manipulation, hematoma generated from the biopsy, and the anoxic period during the mastectomy. Byrd in discussion said the paper underscored the fallacy of the two-stage procedure. Biopsy with subsequent mastectomy had inherent risks, particularly when done at an institution that did not furnish full pathologic capabilities, such as frozen section diagnosis and an ability to process tissue for proper hormone receptor activity.

In a review of 80 patients in 1984 Kohail et al.[70] made a summary statement that estrogen receptor was most predictive of disease-free survival, whereas lymph node status was more important in predicting overall survival.

In 1971 Davis et al.[71] reported two cases of necrosis of the female breast complicating anticoagulant therapy. In both patients, 4 days after initiating treatment with sodium warfarin (Coumadin), the breast became painful and examination revealed a swollen organ with a bluish discoloration. Bullae appeared rapidly and frank necrosis of the breast with a sharp delineation from surrounding normal tissues soon followed. Simple mastectomy was required for treatment. Etiology of the necrosis is unknown, although it is usually unilateral and cessation of the drug does not reverse the process.

Chemotherapy

Chemotherapy of breast cancer has not been emphasized on programs of the SSA. However, the now famous "one rat" experiment was presented by Ochsner[15] in 1926. He first reported the use of colloidial gold in a patient with inoperable breast cancer and obtained partial remission of local, regional, and distant metastatic disease. There had been criticism that the use of colloidial gold would result in fatty degeneration of the liver. Ochsner placed a rat weighing 154 g on a dose of 0.001 g of colloidial gold daily per os and killed the animal after 4 months. At autopsy, there was no sign of fatty degeneration of the liver.

In 1970 Shingleton et al.[72] reviewed the various multi-institutional chemotherapy protocols in use for mammary cancer. The overall response rate was between 25% and 31%. Early data suggested, however, that a combination of drugs was more effective than single active agents. The best response rates for tumor regression (68%) were achieved with a five-drug combination regimen consisting of cytoxan, prednisone, methotrexate, vincristine, and 5-FU. Also, Shingleton discussed a theoretical advantage of initial ablation of endocrine organs and, after relapse, treating secondarily with multiagent chemotherapy. Interestingly, such sequential treatment had not yet been used extensively. The authors arrived at their conclusion by noting that the survival rates from adrenalectomy and from chemotherapy for patients with bone and soft-tissue metastases were approximately the same and, possibly, the sequential application of these treatments might double the duration of the response.

Bilateral Breast Cancer

In 1971 Finney et al.[73] reported 50 patients with bilateral carcinoma of the breast, 13 of which were synchronous. Demonstrable carcinoma *in situ* contiguous to the invasive lesion was quite common and gross multicentricity occurred in five patients. In 1984 Wanebo et al.[74] again addressed the question of bilaterality of breast cancer and suggested a reduction in risk by biopsy of the contralateral breast at the time of definitive treatment of the initial lesion. Sixty-two patients had contralateral biopsies, and 13 patients (21%) had simultaneous contralateral breast cancer, 11 (18%) of which were occult. Six of the lesions were lobular carcinoma *in situ,* four were intraductal carcinoma, and three were invasive adenocarcinoma. Wanebo et al.[74] presented data to indicate that contralateral invasive breast cancer has a grave prognosis and concluded that contralateral biopsy, by identifying breast cancer at its earliest stage, was indicated when a patient has a documented family history of breast cancer, ipsilateral multicentricity, lobular carcinoma *in situ,* or parenchymal patterns on mammography, which make follow-up study by this technique difficult. This presentation produced heated debate. Myers presented evidence to indicate that bilateral breast cancer did not, by definition, have a poor prognosis, and Sutherland concurred. Bland noted the incidence of synchronous bilateral breast cancer to range from 0.27% to 2%, and if Wanebo et al.[74] were to remove lobular carcinoma *in situ* from their study, the detection of synchronous lesions would be approximately the same as that generally reported.

Breast Reconstruction

Lynch et al.[75] reported 14 patients who had breast reconstruction following mastectomy. The gel prosthesis was utilized and, when flap reconstruction was required, the thoracoepigastric region served as the donor site. The authors recommended reconstruction for any well-motivated patient in whom the surgeon was reasonably assured of having eradicated all disease from the chest wall. The reconstructive procedure should follow complete wound healing and the completion of adjuvant therapy. Georgiade et al.[76] recommended immediate breast reconstruction if the tumor was less than 1 cm in diameter or was documented to be an *in situ* lesion. None of the four local recurrences identified in the 50 patients reported by these authors was masked by the reconstructive procedure. Five patients, on final pathologic evaluation, had unsuspected evidence of nipple–areola involvement. The authors did not, therefore, recommend use of the autologous nipple–areola complex for reconstruction. Hartrampf and Bennett[77] presented their extensive series of 300 patients undergoing breast reconstruction utilizing the transverse abdominal island flap. Complications were minimal and chest wall recurrence developed in five patients within a follow-up period of 7–45 months. In one patient, the reconstruction delayed identification of the recurrence by approximately 3 months.

Summary

The development of current concepts in the treatment of breast diseases during the last 100 years is well documented in the *Transactions of the Southern Surgical Association.* Fellows of the SSA have been on the cutting edge of these developments and chose the SSA as the forum to describe and debate their new observations.

Abdominal Trauma at the Southern Surgical Association, 1888–1987

FRANCIS C. NANCE, M.D., F.A.C.S.

From the Department of Surgery, Saint Barnabas Medical Center, Livingston, New Jersey

Since 1888 98 papers have been presented to the Southern Surgical Association (SSA) dealing directly or indirectly with abdominal trauma. The papers reflect the progress over the century in the management of this injury. Almost two-thirds of the papers have originated from the major city hospitals of the south. An interest in abdominal trauma has been manifest among the officers of SSA. Twenty-two presidents have presented papers or taken part in discussions. Four 25-year eras were identified. In the earliest, exploration of abdominal wounds was firmly established as a principle. The second period was characterized by consolidation of principles and strengthening of supportive care. The third era encompassing World War II marked a nadir in productivity. In the last 25 years a reawakened interest has resulted in a marked increase in the number and quality of presentations, which have increasingly focused on specific organ injuries.

THE LOVE AFFAIR of the Southern Surgical Association (SSA) with the subject of abdominal trauma began at the first meeting in 1888 and has continued with undiminished ardor to the present day. Ninety-eight papers dealing directly or indirectly with abdominal trauma have been presented and many of these have profoundly influenced the management of trauma as it has been practiced in the United States. The presence of large public teaching hospitals in most of the major southern cities undoubtedly has contributed to the large number of reports that have come out of the South. Institutions such as Charity Hospital in New Orleans, the Hillman Hospital of Birmingham, Grady Hospital in Atlanta, the Louisville General Hospital, Parkland Hospital in Dallas, and the Ben Taub Hospital in Houston have provided the opportunity for young surgical investigators to make important contributions in the study of trauma and, of course, have served as a training ground for innumerable southern surgeons. The importance of these great institutions can hardly be underestimated. Almost two-thirds of the total number of papers on abdominal trauma had their origin in the records of these great institutions (Fig. 1). The New Orleans Charity Hospital, with its 11 papers, may well have had the most single-minded devotion to abdominal trauma. Since 1893 case records of more than 10,000 patients with abdominal injury have been reported in the literature from that institution alone.

The story of abdominal trauma at the SSA may be conveniently divided into four 25 year eras (Table 1). The first, extending from 1888 to 1912, could be characterized as one that defined the role of surgery in the

management of abdominal trauma. The sense of excitement and adventure that permeated the papers and the discussions of that period is almost palpable. The second era, which includes the first World War, was one of consolidation of principles. Attention was focused on individual management of specific lesions and the general support of the patient before and after operation. The third era encompassed World War II and represented the nadir of productivity with only 15 papers presented to the SSA during this period. The Lessons of War appear to have been taken to heart by most surgeons with uncritical enthusiasm and no one seemed willing to question apparently settled issues. The last era has been characterized by the presentation of 33 papers (Fig. 2), many of them reexamining old dogmas, with nothing left sacred. These papers have played an important role in shaping the modern management of abdominal trauma and continue to open new pathways. While presentations of the earlier eras tended to dwell on the general topic of abdominal trauma, the latter era has focused on specific intra-abdominal lesions (Fig. 3).

The enthusiasm of the membership for abdominal trauma has been shared over the years by our officers. Twenty-two of our past presidents have manifested major interests or have presented papers on abdominal trauma at a meeting of the SSA (Fig. 4).

Discovery and Excitement, 1888–1912

The surgical management of abdominal trauma had its origins just prior to the founding of the SSA. Prior to 1880, no formal laparotomies had been performed for gunshot wounds of the abdomen, and during the Civil War (1861–1865) such wounds were managed by expectant therapy. In 1881 the death of President Garfield from an assassin's abdominal gunshot wound focused attention on the possible role of surgery in this lesion. Garfield had been managed without operation, but by 1882 Professor R. A. Kinloch of Charleston (Fig. 5), a founding member of the SSA, had explored a patient and sutured five intestinal wounds. Unfortunately, the patient had seven intestinal wounds and did not survive.[1] This preliminary attempt was followed shortly by Kocher's successful suture of a stomach wound and Bull's successful closure of an intestinal wound (the first in the United States). In 1887 three papers were presented to the American Surgical Association discussing the propriety of laparotomy for gunshot wounds, among them a paper by Kinloch. A long discussion ensued with important contributions from a number of southern surgeons. By the time of the first meeting of the SSA, the utility of laparotomy for penetrating wounds of the abdomen, in particular gunshot wounds,[3,4] was becoming fairly firmly established.

TABLE 1. *Four 25-Year Eras of Abdominal Trauma at the SSA*

1888–1912	Discovery and Excitement
1913–1937	Consolidation
1938–1962	The Lessons of War
1963–1987	Reexamination and Discovery

The first presentation on this topic to the SSA was at the first meeting, by R. M. Cunningham[2] of Pratt Mines, Alabama, who reported on the case of a Scotch miner who had shot himself with a .38 caliber pistol. He was managed expectantly. Eighteen hours later, signs of peritonitis appeared and the patient died at 52 hours.

The following year, two papers were presented in tandem, dealing with anastomotic techniques for the small bowel. Much of the discussion of these two papers was in the context of the application of these techniques to the management of gunshot wounds. The general tenor of the discussion that followed was that laparotomy should be strongly considered for patients with penetrating gunshot wounds. President Hunter H. McGuire (Fig. 6) of Richmond was perhaps most succinct in reminiscing about his days as a military surgeon in the Civil War: "I look back with horror on the days of the war when I practiced surgery on gunshot wounds to the abdomen. We gave them opium, etc. and waited until they died. Now a man has no right to do this."[5]

Four years later, at the meeting in New Orleans, W. F. Westmoreland of Atlanta came down on the side of laparotomy in his paper on the treatment of gunshot wounds.[6] Westmoreland seemed particularly incensed about some of his less radical colleagues: "The physician calls in the abdominal surgeon and, although he expresses himself very radically about operations involving the removal of ovaries and tubes, when he comes to these cases [abdominal trauma] it is *opium and wait.*

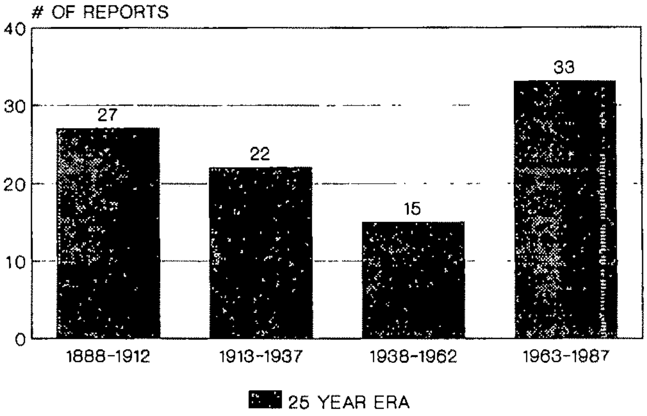

FIG. 2. Papers presented to the SSA by 25-year eras. A nadir of productivity was reached following WW II, but in recent years, there has been a vigorous reawakening of interest with a marked increase in the number and quality of presentations.

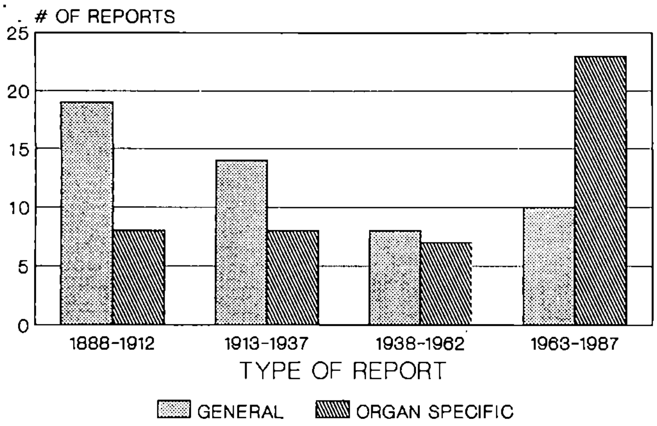

FIG. 3. General *versus* organ-specific reports on abdominal trauma (by era). In recent years an increasing proportion of papers has focused on specific organ injuries. In the earliest era general papers on the suitability of laparotomy dominated the discussions.

When he comes to the bedside and sees the case before him, he does not have the courage of the convictions he has so openly avowed. Particularly, this is true of those gynaecologists and coeliotomists who, like toadstools, spring up in a night." Westmoreland was supported in his views by A. B. Miles of New Orleans, Cunningham of Alabama, and J. McF. Gaston of Atlanta, but J. D. S. Davis of Birmingham expressed some caution about routine laparotomy.[7]

Papers by Tiffany of Baltimore in 1894,[8] and by Bradford Brown of Alexandria in 1895[9] continued the colloquy, climaxed by the paper of W. E. Parker of New Orleans, Louisiana at the meeting in Nashville in 1896.[10] Parker reported on 13 personal cases operated upon at Charity Hospital, New Orleans of whom six survived. He provided an extensive summary of the world's literature on the management of bullet wounds to the abdomen published to that date, and provided excellent descriptions on how to manage individual lesions. Parker's paper provoked a long, excited discussion with the vast majority of the individuals strongly supporting an aggressive employment of laparotomy in the management of gunshot wounds.

FIG. 4. A list of the presidents of the SSA who manifested major interests in abdominal trauma. *Made presentation on trauma at an annual meeting of the SSA.

Finally, Howard A. Kelly of Baltimore rose and made the following proposal: "Would it not be well, Mr. President, in view of the serious medico-legal complications that arise in these cases, to pass a resolution favoring immediate operative interference whenever any of us come in contact with these cases? I, therefore, offer the following: Resolved, that it is the sense of the members of the Southern Surgical and Gynecological Association that in gunshot wounds penetrating the abdominal cavity the proper routine procedure is to make an immediate exploratory incision. Seconded and carried."

One can almost picture Parker being carried from the auditorium on the shoulders of his cheering fellow members! His high standing among his colleagues was to be short-lived.

Two years later Parker returned to the speaker's podium with another paper.[11] In the interim, he had served as a surgeon with the American military forces in Cuba. Parker had entered the conflict with the intention of exploring patients who sustained abdominal wounds, but soon found "surgery with troops in the field is a very different thing from surgery in civil life."[11] He concluded, "Wounds of the abdomen healed without operative interference. When I saw the conditions I strongly advised against surgical management."[11] He had discovered that exploration of abdominal wounds in a military field hospital was too dangerous. His conclusion, it should be stated, was shared by most of the other physicians who had participated in the Cuban expedition and by virtually the entire military surgical establishment. Yet Parker's recantation of his advocacy of laparotomy for penetrating abdominal wounds did not sit well with his audience. One after another of his fellow members rose and denounced him. H. H. Grant of Louisville, who had presented a paper recommending laparotomy for all gunshot wounds,[13] said, "Some of the statements by Dr. Parker are unquestionably astonishing." F. W. McRae[14] from Atlanta had reported on the recent experience at Grady Hospital and reiterated his firm conviction that every case of penetrating wound of the abdomen "where there is reasonable doubt as to injury of the abdominal viscera should be subjected, at least, to an exploratory operation." One or two faint voices were raised in support of Parker, but the discussion continued with a reiteration of Kelly's resolution from the 1896 meeting and the accusation that Parker was advising "masterly inactivity."[2] Westmoreland went further: "It's not 'masterly inactivity,' it is '*criminal inactivity.*' " Parker, in fact, had not changed his position on civilian gunshot wounds. He still advocated exploration for these lesions.

Grant was so incensed that the next year he presented another paper continuing his denunciation of Parker and concluding "With these facts before us, it is clear that to delay, in a delusive hope, until peritonitis shows its folly is almost a crime. The practical management of a suspected penetrating wound is as plain a duty as the tying of a bleeding artery. As soon as possible after injury, the patient is to be transported to a suitable place [and explored]."[15] And lest there be any doubt about how he stood about Parker's recommendations: "Because a man falls out of a balloon from a considerable height . . . without sustaining injury is that any reason why we should encourage others to undertake similar experiences?"

Undaunted, Parker stood his ground saying that he had not operated on a gunshot wound to the abdomen for about 3 years and reiterating the firmly held belief by the military that operations in the field could not be performed safely. (This conclusion of the military surgeons, shared by the British, continued until 1915.)

Another dozen papers over the ensuing years[16–23] continued the argument with ill-tempered comments about the military surgeons and about Parker continuing until 1915. The most important of these subsequent papers was that of E. D. Fenner[17] of New Orleans who updated the Charity statistics presenting 152 cases (which was a larger series than that experienced by the army during the Spanish American War). Parker, in the meantime, resigned from the SSA and retreated to Hot Springs, Arkansas.

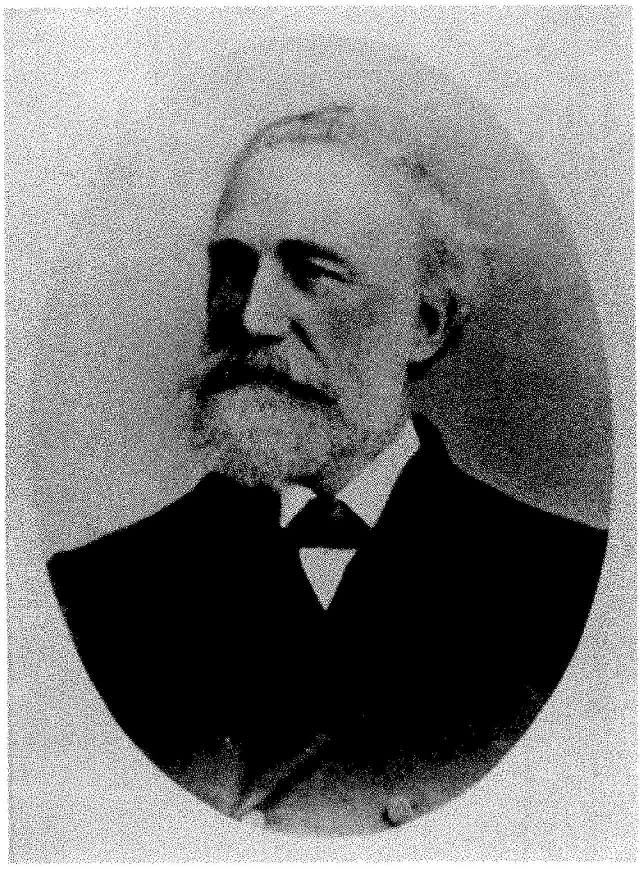

FIG. 5. Professor R. A. Kinloch of Charleston, a founding member of the Southern Surgical and Gynaecological Association. He was the first American to explore a patient with a gunshot wound of the abdomen.

FIG. 6. Hunter H. McGuire of Richmond, a founding member of the SSA and an early proponent of laparotomy for trauma. He had served as Stonewall Jackson's surgeon and was perhaps the most respected and influential trauma surgeon of his day.

An interesting sidelight of this era was the formidable presence of Nicholas Senn. Senn was elected to membership of the SSA in 1893 and was a member until he resigned in 1905. No evidence could be found that he actually attended a meeting, but the rise and fall of his influence at the meetings makes an interesting story.

Senn was perhaps the most prolific intestinal surgeon of his era, with a deep interest in abdominal trauma. He had developed a variety of techniques of intestinal anastomosis, had invented the Nicholas Senn hydrogen gas insufflation test for diagnosis of abdominal visceral penetration,[24] and was the founder of the Association of Military Surgeons (Fig. 7). Senn's hydrogen gas test consisted of insufflating hydrogen through a tube in-

FIG. 7. Nicholas Senn of Milwaukee, a prolific student of abdominal trauma whose presence was very much felt during discussions of abdominal trauma in the first decade, founder of the Association of Military Surgeons.

serted into the anus of a wounded patient. The patient was then examined for abdominal distention and tympani. A lighted taper was placed near the wound of entrance. A small explosion accompanied by a flaring blue flame was a positive test, indicating penetration of the intestines. The value of this test was stressed by Cunningham in his first paper on abdominal trauma in 1888 when he expressed his opinion that the Senn test would have made the diagnosis in his patient and led him to earlier exploration.[2] The papers on intestinal anastomosis the following year paid tribute to Senn's seminal contributions in intestinal anastomosis.[3,4] There were repeated favorable references, both to the hydrogen gas test and to Senn's contributions in these papers and in the discussion which followed. McGuire was typical: "I think the whole profession is greatly indebted to Dr. Senn" and J. D. Davis emphatically said: "I don't open up the abdomen when I have the hydrogen gas with me until I have used it." Senn's ascendency continued through Parker's presentation of 1896,[10] but when Senn supported Parker's views about the management of abdominal wounds in the military,[25] he might as well have written his epitaph. By the next year, Grant was calling the Senn test "worse than useless." McRae went further: "the gas test of Senn is worse than useless. It is dangerous" And W. E. B. Davis, who in previous years had made complimentary remarks about Senn, was moved to say, "Dr. Senn's influence has been harmful. Every Community has suffered from his writings." Senn's opinions and writings disappeared from the transactions and no further favorable reference to him can be found. Senn's name does not appear in any subsequent discussions. He resigned in 1905, whether or not at the instigation of the council is not recorded. It is notable that in a presentation celebrating the 50th anniversary of the SSA, Hubert Royster spoke as if Senn had actually attended a meeting. This is strong evidence of his forceful influence.

Seventy-five years later, a young perhaps foolish member* had the temerity to advocate again "masterly inactivity" in the management of gunshot wounds of the abdomen.[26] Perhaps, if he had known at that time the fate of Parker and Senn he would have been more cautious!

Consolidation, 1913–1937

This era was marked by considerably more civility in the discussions about abdominal trauma. Just prior to the beginning of this era, W. D. Roberts of Louisville had given a presidential address on Southern Surgeons, reminding his audience that he himself had performed the first successful exploration of a stab wound in 1884.[27] John W. Brown's presidential address of 1913 was a superbly comprehensive paper on the management of acute abdominal conditions, including abdominal trauma.[28]

With the coming of the World War, there was a renewal of interest in the military aspects of trauma. The 1914 meeting had three papers dealing with military surgery.[29] The paper of H. D. Marcy of Boston paper was an affectionate reminiscence, 50 years later, of his experiences as a young military surgeon in the Yankee Army during the occupation of Charleston, South Carolina.[30] His description of the hardships endured by the Yankee soldiers apparently fell on deaf ears and the paper was not discussed. Colonel Charles Richard of the U.S. Army, a guest speaker, reiterated the military's continuing position that formal exploration of the abdomen for penetrating gunshot wounds should not be undertaken unless there was evidence of uncontrolled hemorrhage.[31] This position of military surgeons still rankled and Colonel Richard was subjected to pointed questioning during the discussion. The members of the SSA were, of course, right on this issue and the military abandoned its position shortly following the start of the war.

---

* The author is referring to his own epochal work in this field (Ed).

W. L. Haggard of Nashville was moved to wax patriotic in his presidential address of 1917.[32] C. H. Peck of New York returned from the front in 1918 to describe the treatment of war wounds in the hospitals of the expeditionary forces.[33] The 1920s brought a focus of interest in improving the supportive care of patients with abdominal injuries. A. M. Willis of Richmond reported on some clinical and experimental observations in the use of saline irrigations in diffuse peritonitis due to trauma.[34] Mason presented a paper on the influence of hemorrhage in the mortality of gunshot wounds of the abdomen.[35] Mason and the program committee were so impressed by this paper that he gave a second one with the same title the following year.[36] Mason divided his series into two groups, a large hemorrhage group of patients, and a small hemorrhage group. The large hemorrhage group had a mortality rate of 90%, whereas the small hemorrhage group had a mortality rate of only 30%. He concluded that hemorrhage was an important factor in the mortality rates of these patients and strongly advised the use of blood transfusions, a conclusion that was supported by many of the discussants.

Later in the era, there occurred a brief infatuation with shotgun wounds of the abdomen, beginning with the report of G. H. Bunch, of Columbia in 1928[37] of four patients who sustained close-range shotgun wounds; three died. Of three with long range shotgun blasts, two died. Bunch advocated early exploration, a position seconded by most of his discussants. Mason was back again during the discussion giving a minipaper reiterating the increase in mortality associated with hemorrhage in gun shot wounds of the abdomen.

Willis[38,39] followed Bunch's paper in 1931 with a report on penetrating wounds of the abdomen from pistol, rifle, and shotgun missiles and emphasized that long-range shotgun wounds with scattered shots could be managed nonoperatively, a position he soon supported with a paper in 1934 reporting a series of animals wounded with long-range shotgun blasts in which more than one-half of the animals survived without operation. Willis' 1931 report was also notable: 63 cases, all treated in the tiny hamlet of Rocky Mount, North Carolina. L. H. Landry, from New Orleans, in discussing Willis' paper, brought the audience up to date on recent Charity Hospital statistics, which included a total of 3141 gunshot injuries treated from 1914 to 1924.[40]

Perhaps the most important major presentation from this era was that of Heuer[41] who reported on 7000 cases of major trauma seen at the Cincinnati General Hospital, among which there were 334 patients with abdominal injury treated with a mortality rate of 50% for gunshots and 13.2% for stabs. This paper stimulated a general discussion on the importance of establishing trauma as a specialty and the need for establishment of special training in trauma surgery.

The Lessons of War, 1937–1962

The war in Europe had begun when Storck[42] presented his paper on penetrating wounds of the abdomen. It was a series of 46 cases operated on personally, with a mortality rate of only 40% among the gunshot wounds. This very long, impressively documented paper extensively described the proper management of penetrating wounds of the abdomen and served as the basis for his manual on the management of abdominal trauma, which became an official army document. The following year, with war raging in Europe, a symposium on war injuries was given, with Storck[43] again making the presentation on abdominal wounds. During the war, there were papers by M. E. DeBakey and B. N. Carter[44] on war surgery, DeBakey and F. A. Simeone[45] on vascular injuries, and Lt. Col. L. G. Lewis[46] on pelvic injury, a remarkably small output considering the number of surgeons who participated in the war. In the early post-war period, there was a marked drop-off of interest in trauma, perhaps reflecting a general conviction that war surgery had provided all of the answers for the management of abdominal trauma. This view clearly was reflected in the paper of D. H. Poer of Atlanta in 1947, which strongly recommended applying military surgical principles to civilian trauma.[47]

The era closed with an important paper by Wilson and Sherman.[49] This presentation was a harbinger of things to come in a later era and set the stage by raising questions about the appropriateness of universal application of military principles to civilian trauma.

Only 15 papers were presented during this era, representing a nadir of interest and productivity perhaps reflecting a post-war attitude that all of the important issues had been answered.

Reexamination and Discovery, 1963–1987

The most recent era has been characterized by a marked increase in the interest in the general subject of abdominal trauma and a focus on the more specialized aspects of specific organ injury. Heated discussions, new ideas, and a willingness to challenge old precepts returned in full force to the forum of the SSA. J. E. Pridgen's[50] presentation in 1966 on penetrating wounds of the abdomen reported on 776 cases from the University of Texas in San Antonio and provoked discussions on the advisability of exploration for stab wounds. F. C. Nance's[26] paper in 1973 extended this discussion. By this time, the concept of selective management of stab wounds was being grudgingly accepted in a number of trauma institutions, but Nance's inclusion of gunshot wounds as candidates for selective nonoperative management was greeted with deep suspicion, if not hostility. The discussion was continued in 1983 when W. C. Lee, J. F. Uddo, and Nance presented the Charity Hospital experience with selective management of stab wound reiterating the conviction of the LSU group in New Orleans that clinical criteria alone were sufficient to decide whether or not a patient with a stab wound needed exploration. These authors reported a negative laparotomy rate of 7.8% and a mortality rate of 2.2%. One death from inappropriate application of their protocol was acknowledged.[51] D. V. Feliciano of Houston, in discussing this paper, reiterated the reliance at Ben Taub Hospital on local wound exploration, a policy also followed by L. M. Flint Jr. in Louisville. A. V. Donovan of Los Angeles supported the authors, saying that clinical criteria were utilized in Los Angeles in the evaluation of patients.

Specific Organ Injuries

An important aspect of the bibliography of abdominal trauma of the SSA has been the papers that have focused on specific organ injuries. As laparotomy became firmly established, a concentration on management of individual lesions became inevitable. The trend has become much more pronounced as very large series of patients from the major trauma centers became the subject of comprehensive study.

Diaphragm

Three case reports constitute the total discussion of diaphragmatic injuries at the SSA. The first report was given in 1904 on a patient who had sustained gangrenous changes to the bowel; the patient died.[52] The other two cases were patients diagnosed 6 and 7 weeks postinjury in whom successful elective repairs had been accomplished.[53,54] All of the authors emphasized the difficulty in making the diagnosis of ruptured diaphragm (which is perhaps understandable because in all of the case reports the diagnosis had been delayed).

Vascular

Past presentations on vascular injuries have been made nine times beginning with LaRoque's report of an A-V fistula following a bullet wound to the external iliac artery and vein that he managed by ligation of both vessels.[55] The patient and his extremity survived. In describing his concern about the vascular supply to the leg, G. P. LaRoque of Richmond comments that a week after the operation, "I took the liberty of sticking a pin in his toe to see if it would bleed. It bled."[55] LaRoque finished his paper by including a thorough review of the available literature on the lesion, paying tribute in particular to the contributions of Halsted and Matas. LaRoque returned the next year with another paper.[56] At least LaRoque had the modesty to quote a "distinguished American surgeon" as having "prayed to be delivered in time of illness from the care of a doctor who has had *a* case. Might he not with equal fervency pray to be delivered from the surgeon who's opinions are firmly fixed after the successful management of *another* case."[56] This patient was also treated by ligation and survived with an intact leg.

In 1928, an aortic injury was reported by J. G. Sherrill of Louisville in a patient who sustained severe blunt trauma. He developed a thrombosis of the distal aorta. Sherrill had attempted thrombectomy but, unfortunately, his patient did not survive.[57] He was congratulated for his courage by the members during the discussion.

The modern papers on vascular injury began with DeBakey and Simeone's review of arterial injuries encountered during World War II, presented at the meeting in 1945.[45] This classic presentation reviewed 2471 cases of arterial injury and has served as a milestone for all subsequent reports on arterial injuries. The paper included a discussion of 47 intra-abdominal arterial injuries.

Most other presentations on arterial injuries have dealt in passing with the abdominal vessels. The presentation of Hardy et al.[58] in 1974 described their experience in Jackson with 22 abdominal aortic and 44 other abdominal vessels among 360 arterial injuries. Reynolds et al. reviewed 20 abdominal vessels among 191 patients with arterial injuries.[59] Feliciano et al.[60] reported on 408 patients with vascular injuries seen in 1 year, among them being 130 patients with abdominal arterial injuries. Many of the patients in this series were treated with prosthetic bypass or insertion of a venous conduit.

McCune et al.[61] dealt with the specialized problem of mesenteric thrombosis following blunt trauma. They emphasized the high mortality rate associated with the lesion, having observed three deaths among the four reported cases.

In 1974 Mattox et al.[62] presented a series of 22 patients with injury to the portal vein of whom 11 survived. The authors recommended lateral repair, end-to-end anastomosis, or portacaval shunt because ligation was associated with a 100% mortality rate.

The consensus of opinion regarding vascular injuries to the major abdominal vessels revolves around the need for early diagnosis and control of hemorrhage. Virtually all reports and discussion confirm the need for direct arterial repair and/or anastomosis where feasible, or insertion of a variety of prostheses where primary repair is not possible.

Urology

Six presentations before the SSA have dealt with trauma to the urogenital tract. Two papers presented in successive years, 1917 and 1918, reported on injuries to the kidney. J. M. Mason's paper reviewed the literature and presented three cases.[63] Mason and the majority of the discussants of the paper favored nephrectomy or suture of the injury.[63] There was considerable discussion about the virtues of suture with a general consensus that the kidney should be preserved if possible. The following year, S. G. Ledbetter[64] also presented a case of kidney rupture treated by suture with survival, and in the discussion, T. S. Cullen, among others, strongly supported his view.

Wounds of the urinary bladder were first discussed by R. Douglas of Nashville in 1893.[65] He described a patient who had had a bladder ruptured by the shaft of a buggy. After determining that it was an extraperitoneal injury, Douglas managed the patient by simple drainage apparently without a bladder catheter; the patient recovered fully.

Other papers have dealt with bladder injuries associated with pelvic fractures.[66] In 1944, a guest speaker, Lt. Col. L. G. Lewis[46] described four severe war injuries and W. L. Weems of Jackson[67] discussed a series of 86 GU injuries identified in 282 patients with pelvic fractures. Both authors recommended suprapubic cystostomy through a small lower abdominal transverse incision with appropriate drainage. Weems' paper made an excellent case for delayed repair of urogenital lesions, relying initially on suprapubic cystostomy and drainage and making a formal repair at a later time.

Pelvis

Only one paper over the years has dealt specifically with pelvic injuries, that of Flint et al.[68] of Louisville, which was presented in 1978. (Two other papers dealing with the pelvis focused on genitourinary injuries.) Flint's paper defined a subgroup of patients with pelvic fractures who had severe extraperitoneal hemorrhage and described the use of a G-suit with inflation to control hemorrhage from this severe complication. One of their patients was managed by angiography, a method that might well be regarded as the method of choice at the present time.[68]

Spleen

Four papers on splenic trauma have been presented to the SSA. They reflected the cyclic evolution of the management of splenic trauma over the past century. Tiffany's presentation in 1894 discussed a patient with a gunshot wound of the spleen managed by suture. The tenor of the discussion was that splenic trauma could be managed either by suture or splenectomy.[8]

W. P. Carr's presentation in 1906 also described management of splenic trauma by suture or splenectomy, but Carr recommended a splenorrhaphy only for "injuries that can be safely repaired."[69] By 1917, A. M. Willis of Richmond was advocating splenectomy for all splenic trauma.[34] This rather rigid approach continued and was epitomized by the discussion of J. H. Morton's paper on blunt trauma in 1956 in which one of the members stated "the treatment for ruptured spleen is, of course, splenectomy."[70]

The report in 1952 by King and Shumacker[71] first called attention to the risk of overwhelming infection following splenectomy in infancy. Subsequently, other reports led to a reevaluation of the management of splenic trauma. A history of this reevaluation was summarized by R. T. Sherman of Tampa in 1980.[72]

By 1984 Feliciano et al.[73] presented a series of 305 patients with splenic injury managed by selective splenorrhaphy and splenectomy. Forty-five percent of the patients had splenorrhaphy and 55% of the patients had splenectomy; they concluded that splenectomy would be generally required in patients with multiple associated intra-abdominal injuries and the more severe grades of splenic injuries and that splenorrhaphy could be performed in patients with a smaller number of associated intra-abdominal injuries and less severe grades of splenic injury.[73]

The operative management of splenic injury had thus come full circle to the point where it existed in 1894, namely, splenic injuries are treated selectively, either by suture when possible, splenectomy, or by nonoperative management.

Liver

Martin's presentation in 1946 marked the first time that a paper dealing specifically with wounds to the liver had been given to the SSA.[74] Martin's paper dealt with an experimental injury inflicted to dog livers by hitting each liver 50 times. He reported that hemorrhage following this type of injury could be controlled by packing and debridement.[74] Discussion included a comment by DeBakey reporting on his war experiences with liver trauma and emphasizing external drainage and control of shock.

Sparkman and Fogelman[75] of Dallas presented a summarized series of liver trauma patients from the Parkland Hospital in 1953. The series was subsequently updated by Trunkey et al.[76] in 1973; 811 patients were managed primarily by suture and drainage. However, almost 6% of the total were managed by major resection. A subsequent report by Flint et al.,[77] and the discussion following it, reiterated the importance of less aggressive treatment of hepatic injuries utilizing hepatic artery ligation, selective debridement, drainage, and packing.

Sandblom et al.[78] presented an experimental study in 1975 on healing of liver wounds, demonstrating that the presence of bile greatly slowed the rate of healing of liver wounds.

The paper presented by Busuttil et al.[79] in 1979 dealt with extrahepatic injuries to the portahepatis, including bile duct and portal vein injuries. A total of 28 patients was presented with a variety of repairs recommended as would be expected in this diverse group of injuries.

The most recent paper, that of Pachter et al.[80] emphasized the use of finger fracture technique to allow local control of hemorrhage from hepatic injuries. This paper reiterated the more modern view that these injuries should be treated selectively with minimal reliance on major resections. The discussion that followed emphasized the use of packing in patients with massive hepatic hemorrhage.

The presentations on hepatic trauma at the SSA have reflected changes in attitude that have evolved since 1945. In the 1950s and 1960s there was enthusiasm for aggressive approach to hepatic trauma utilizing major resections. This has gradually changed to one that calls for minimal debridement of necrotic tissue and simple repair by any means that will effectively control hemorrhage. A brief interest in hepatic artery ligation and in common duct drainage appears to have been abandoned by most recent authors.

Pancreas and Duodenum

The first presentation dealing specifically with injuries to the duodenum and pancreas was not made until 1963, which is perhaps understandable considering the complexity of pancreatic and duodenal trauma. Moore and Erlandson dealt with intramural duodenal hematoma.[81] They presented two cases and reviewed 33 others in the literature. Surprisingly, they made no mention of conservative, nonoperative, treatment, nor did they make any mention of of serosal incision as a method of management of duodenal hematoma. These issues, however, were brought up during the discussion and by the time of a second presentation on the same subject by Fuller et al.,[82] nonoperative management in selected patients had become well established and was recommended.

Barnett et al.[83] reviewed the experience of the University of Mississippi in the management of pancreatic injury yielding an overall mortality rate of 13%. Barnett's group relied primarily on drainage. One-third of the 18 patients were treated by distal pancreatectomy and drainage; only one death had occurred.

Several groups have presented large series of patients with duodenal, pancreatic, or combined injuries. The recommended therapies have generated significant controversy in the discussions that followed the presentations. Flint,[84] in discussing duodenal injury, recommended tube decompression of the duodenum through an enterotomy stating that no duodenal fistulas had been observed in any of the ten patients so treated. The majority of duodenal injury patients were treated by suture with a few being treated by other means, such as anastomosis, pancreaticoduodenectomy or duodenojejunostomy.

Jone's report[85] emphasized his preference for anastomosing a Roux-en-Y limb of jejunum to the injured pancreas, which he had employed in 38 of his 274 patients. Drainage alone, either by Penrose or sump, was performed in 197 of the 274 patients.

The presentation by Feliciano et al.[86] emphasized their preference for "duodenal diverticulization" in which the pylorus is closed by absorbable or nonabsorbable sutures and a proximal gastrojejunostomy is constructed. This method was utilized in 68 of 129 patients with combined pancreaticoduodenal injuries. In discussions following this paper, H. H. Stone from Grady Hospital in Atlanta emphasized his preference for triple intubation (gastrostomy, jejunostomy tube extending proximally into the duodenum, and jejunostomy tube extending distally into jejunum for feeding) and F. C. Nance expressed his discomfort with all of these methods, preferring simple reliance on sump drainage, distal pancreatic resection, and occasional pancreaticoduodenectomy.

The controversy over the role of pancreacticoduodenectomy for trauma raised in other forums has seldom been a cause for discussion at the SSA. Salaam et al.[97] reviewed four patients who had been followed 3 years after surviving Whipple procedures for trauma and reported that all were biochemically and physiologically normal. Most large series have included a few patients who were managed by pancreaticoduodenectomy with mortality rates ranging from 20% to 40%.

It seems clear that the management of pancreatic and duodenal injuries is in a state of flux and will be a continuing subject of discussion at future meetings of the SSA.

Esophagus, Stomach, Small Bowel and Colon

There have been ten papers over the years that have dealt with wounds of the hollow viscera. Symbas et al.[87]

report in 1979 included seven patients, among 48 with esophageal injuries who had gunshot wounds of the abdominal esophagus. Four patients were managed by primary repair, or by repair and plication with survival and no sequelae. Two patients had exteriorization of the esophagus because of the extensive injury. These two patients also survived. Symbas et al.[87] recommended early exploration with primary repair of the esophageal wound and plication with adjacent serosa if possible.

W. M. Jordan's report from Birmingham in 1904[88] was the only one to deal solely with stomach injuries. He reported two patients, one of whom had survived. He recommended purse string suture of the stomach wound and appropriately advised searching for the wound of exit in the retrogastric space.[88]

At the second meeting of the SSA, in 1889, two major papers on intestinal anastomosis based on experimental studies were presented.[3,4] Both dealt extensively with repair of small bowel injuries following penetrating trauma. Davis had done an experimental study utilizing a catgut mat as partial support of the anastomosis. A. V. L. Brokaw from St. Louis, presented a series of experiments utilizing rubber rings. Both authors made it clear that the utility of these techniques was primarily for penetrating trauma to the gut. An extensive discussion of both papers followed, including comments by Hunter McGuire of Richmond (perhaps the most respected trauma surgeon of his day), W. O. Roberts of Louisville, and W. E. B. Davis of Birmingham. A striking feature of both the presentations and the discussion is the repeated reference to Nicholas Senn and his pioneering efforts in developing anastomotic techniques. Both Davis and Brokaw acknowledged Senn's contributions in their papers and in their closing remarks.

Three other papers dealing with intestinal injury took the form of case reports. The most notable of these papers was that of A. B. Miles[89] of the New Orleans Charity Hospital wherein lies an interesting story (Fig. 8). Miles reported on a patient who shot himself while carelessly handling his own pistol. The Charity Hospital ambulance brought him to the hospital and he was on the operating table within a half hour of injury. Sixteen small bowel lacerations and three mesenteric wounds were identified and repaired by suture. He made an essentially uneventful recovery. Miles first reported this case to the SSA in 1890. As a young professor of surgery at Tulane, he was undoubtedly aware of the need to publish or perish and this case report appeared in no fewer than four additional publications. Moreover, the patient was mentioned on at least four subsequent occasions during meetings of the SSA. In 1907 during a clinical visit to Charity Hospital, the members of the SSA were given the opportunity to meet the sturdy survivor some 18 years after his injury!

The SSA has had three important presentations on colonic injury, all subsequent to 1970. During World War II, mandatory colostomy for all colonic injuries, no matter how trivial, had been introduced as a method of therapy and had been largely credited for the improvement in survival noted among patients who sustained injuries to the colon. The principle of mandatory colostomy was enthusiastically adapted to civilian practice and became firmly ingrained in clinical protocols at major trauma institutions.

FIG. 8. A. B. Miles of New Orleans, an early vigorous participant in the discussions on abdominal trauma until his untimely death in 1893 at the age of 42.

The enthusiasm for the use of colostomy for all colonic injuries continued despite a number of reports beginning with that of Woodhall and Ochsner[90] suggesting that many civilian colonic injuries could be more safely managed by primary suture repair. These reports had little impact on surgical practice.

The 1971 paper by Beall et al.[91] continued a series of reports from Houston strongly endorsing selective employment of primary suture for colonic injury. This was followed in 1981 by Flint et al.,[92] who strongly endorsed selective utilization of primary suture.[92] In a discussion of this last paper, Harlan H. Stone's prospective study on colon injury was favorably commented upon and a number of the discussants strongly advocated a wider application of primary suture for colonic injury.

The most recent paper presented by Burch et al.[93] in 1985 was a further update of the Houston series, continuing to reiterate the virtues of selective employment of primary suture. These three papers, and others in the recent trauma literature, have served to modify slowly the approach away from the army's mandatory colostomy for all injury towards a more selective approach to colonic trauma.

Blunt Trauma

Four papers have dealt specifically with blunt trauma, although many others have included patients who sustained nonpenetrating injury. Landry's paper in 1934 on football injuries included eight patients who had experienced hematuria, two of whom required nephrectomy.[94] In 1938, F. W. Baily[95] of St. Petersburg presented 100 cases in whom a 34% mortality rate had occurred. The majority of patients were transportation injuries. In 1956, Morton et al.[48] reported on 120 cases treated in Rochester, NY. The most commonly injured organ was the spleen, which these authors felt should be routinely managed by splenectomy. Davis et al.[96] reviewed 437 patients from the Charity Hospital in 1975. A mortality rate of 13.3% was observed, mostly in patients with concomitant head injury. Clinical criteria for evaluation were recommended.

Summary

One cannot come away from a reading of these 98 papers without acquiring a sense of the gusto, enthusiasm, and downright enjoyment that the members of the SSA have had in wrestling with the topic of abdominal trauma. Discussions have been spirited and tough, occasionally boisterous, but usually gentlemanly. New ideas have been presented and challenged, accepted, or rejected. Young men have questioned long-held established principles, and older men have freely shared their wisdom. As a result, the forum of the SSA has been one of the important sources of progress in the field of trauma management. Members of the SSA may be perhaps forgiven if they concur with one of their former presidents, F. W. McRae of Atlanta, who in 1908 said: "When the history of gunshot wounds of the abdomen shall have been written, chief credit must be given to Southern surgeons. Most of the papers on this subject that are worthwhile have been written by fellows of this Association and have been printed in its Transactions."[22]

Gastroduodenal Ulcer

Overview of 150 Papers Presented Before the Southern Surgical Association 1888–1986

J. LYNWOOD HERRINGTON, JR., M.D.*

From the Department of Surgery, Section of Surgical Sciences, Vanderbilt University Medical Center and the Surgical Service of St. Thomas Hospital, Nashville, Tennessee

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION was formed in Birmingham, Alabama, October 12, 1887. The first scientific session was held in Birmingham the following year on December 4–6. Forty-one charter members were in attendance along with 50 visitors.

This presentation is an overview highlighting some of the important contributions in the surgical treatment of gastroduodenal ulcer disease and its complications by members of the association. A total of 150 papers were presented on this subject from 1888 through 1986. Many important reports cannot be mentioned in this brief review. Emphasis will be placed on the changing patterns of the surgical treatment of ulcer disease that have occurred throughout the years as reflected in the papers by members of the association.

The inaugural presidential address in 1888 was delivered by W. D. Haggard, Sr., of Nashville (Fig. 1). Haggard praised the founding of the association, and in eloquent language outlined the aims and goals for its future in American surgery. He also cited the outstanding accomplishments of two deceased southern surgeons, J. Marion Sims and Ephraim McDowell.

After the presidential address, it is of interest that the first scientific presentation was related to gastric surgery. William Boddie Rogers of Memphis reported on "The Operation of Gastrostomy with a Report of a Successful Case" (Fig. 2). Rogers was a native of Tennessee who had attended Vanderbilt University and graduated from Bellevue Medical College. He later became Professor of Principles and Practice of Surgery at the Memphis Hospital Medical College in 1886, and was later Dean of that institution. He maintained both of these positions until the Memphis Medical College merged with the University of Tennessee in 1913.

Rogers described a gastrostomy performed on a 24-year-old man with an extensive esophageal stricture which followed the ingestion of lye. The operation was carried out under chloroform anesthesia, and the anterior wall of the stomach was sutured to the anterior abdominal wall. On the 10th postoperative day after adhesions had sufficiently sealed the opposing gastric and abdominal walls, a permanent opening was made in the stomach for feeding purposes. The patient was allowed out of bed on the 14th postoperative day and was discharged in good condition on the 26th postoperative day. Although gastrostomy had originally been suggested in 1837 by Egeberg, the Norwegian military surgeon, it had never met with real success until the report of Sidney Jones of London in 1876. Both D. Hayes Agnew and Samuel D. Gross of Philadelphia decried the operation because it was associated with a high morbidity and mortality even in 1878. The report by Rogers represented a real landmark, and he advocated the operation not only for benign esophageal stricture but also for extensive esophageal malignancies. It is of interest that Rogers presented the patient in person before the association. Rogers believed that the high recorded mortality rate could be explained in part by the procedure being done by inexperienced surgeons.

For the next 15 years no presentation addressed the topic of gastroduodenal ulcer. Numerous papers were presented on the manifestations and treatment of ap-

---

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

pendicitis, pelvic infections, pelvic tumors, treatment of fractures, bone tumors, removal of bladder stones, prostatic operations, and ligation of blood vessels.

From 1903 through the 1930s, a group of interesting papers on gastroduodenal ulcer were given. Simple gastrojejunostomy was mainly the operation of choice for both duodenal and gastric ulcer during the early years and was also advocated by some for the treatment of operable as well as inoperable gastric carcinoma.

In 1903, John Blair Deaver of Philadelphia read a paper, "On Gastroenterostomy," in which he reviewed the historical aspects of the operation and described its widespread usage in treating obstructing pyloric carcinoma, duodenal and gastric ulcerations, gastroptosis, acute dilatation of the stomach, pylorospasm, tabes dorsalis, and various functional disorders. He made the important statement that a chronic ulcer in the vicinity of the pylorus might require a pylorectomy. Deaver made a plea for early operation in cases of gastric ulcer and believed if simple gastroenterostomy was done early, the subsequent development of gastric cancer could be avoided. He favored gastroenterostomy as a prophylactic operation as it was widely taught that many cases of gastric ulcer underwent malignant degeneration. He favored a short loop retrocolic gastrojejunostomy, and mentioned the prevention of circulus vitiosus by the addition of pyloric occlusion to gastrojejunostomy. In later years, Deaver largely abandoned gastroenterostomy and advised some type of gastric resection. Deaver was described by his colleagues as being rough, ready, and radical.

In 1906, Herman Tuholske of St. Louis described the unique and interesting experience of observing Professor Theodor Billroth of Vienna perform the first successful pylorectomy on Theresa Heller for pyloric carcinoma January 29, 1881. Tuholske gave the impression that distal gastric resection was done with misgivings, watched with disapproval, and was a bold surgical exercise without permanent beneficial results. He stated that gastroenterostomy performed for definite indications and using proper methods forms one of the most brilliant chapters in the advance of surgery. He advised gastroenterostomy for treatment of gastric ulcers even in the presence of hemorrhage without excision of the ulcer, and without looking for bleeding points. He violently opposed the resectional teachings of Ludwik Rydygier, the Prussian surgeon who had done the first successful gastric resection for a benign gastric ulcer in September 1881. Although gastric carcinoma and gastric ulcer had been defined near the turn of the century as representing separate disease entities, this fact was not fully appreciated by many leading surgeons of the time.

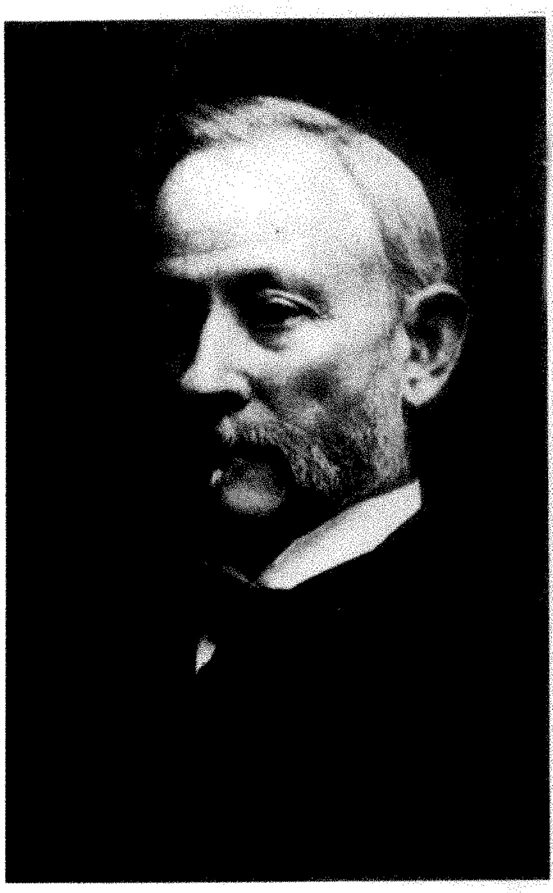

FIG. 1. William David Haggard, Sr., Nashville, Tennessee.

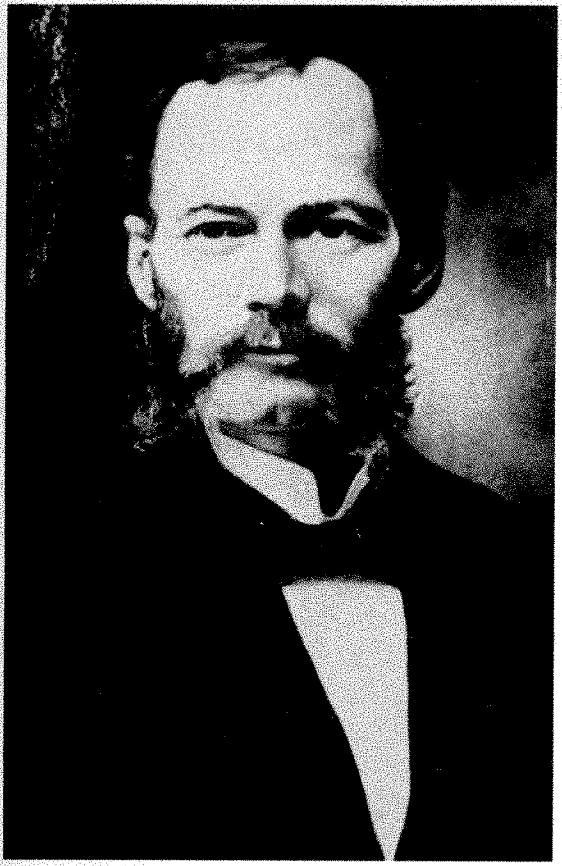
The first attempt at pylorectomy in America was by Randolph Winslow of Baltimore in 1884 (Fig. 3). Unfortunately the operation was unsuccessful. In 1921, Winslow became the 34th president of the association. Also, in 1884, Joseph Ransohoff of Cincinnati performed the first gastroenterostomy in America, the indication being a pyloric cancer, but the operation was not a success. Anton Wolfler had done a successful case in Billroth's clinic in September 1881. Ransohoff was elected to fellowship in the Southern Surgical and Gynecological Association in 1900. William L. Rodman of Philadelphia performed the first successful pylorectomy in this country and presented his case before the American Surgical Association in 1900 (Fig. 4). Rodman was likewise a member of the Southern Surgical and Gynecological Association and his son, Stewart later became a member.

In 1907, J. Garland Sherrill of Louisville was the first to describe before the association a distal gastric resection done for gastric ulcer, and the operation was successful. He was among the first to stress the importance of distinguishing between gastric ulcer, duodenal ulcer, and gastric carcinoma.

In the early 1900s, acute gastric dilatation following gastrojejunostomy was a frequent complication associated with high morbidity and mortality. It also was



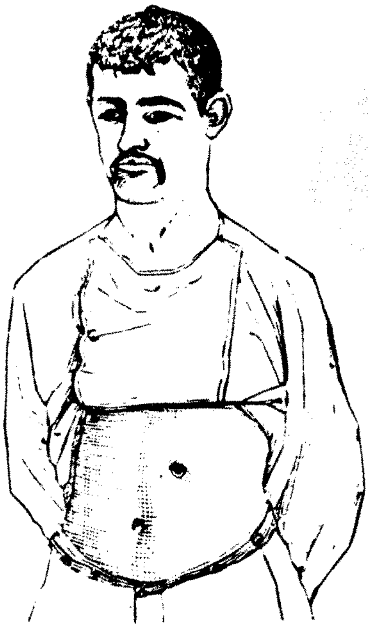


FIG. 2. William Boddie Rogers.

observed as a complication of other operations. Thomas C. Witherspoon of Butte, Montana and George A. Hendon of Louisville discussed the complication in depth, and were puzzled as to the cause and believed that all known methods of treatment generally gave unsatisfactory results.

James E. Thompson of Galveston (no relation to our JIM), presented a paper in 1912 on "Fatal Hemorrhage from Erosion of the Gastroduodenal Artery by Duodenal Ulcer." Thompson later became the 32nd president of the association. It was the general opinion of many surgeons that a gastroenteric shunt would arrest active hemorrhage as a result of diverting the gastric contents. Thompson was among the first to suggest either excising the bleeding ulcer or suturing the anterior and posterior walls of the duodenum at the site of the ulcer. Floyd McCrae of Atlanta, the 17th president, stated that he had witnessed one of the associates of Berkeley Moynihan of Leeds carry out such a maneuver. Moynihan was an honorary member of the association. Thompson mentioned two patients in whom he did not attempt to arrest hemorrhage while performing gastrojejunostomy and stated that he had allowed his two patients to slip through his fingers.

In 1912, Frank Martin of Baltimore described two successful cases of pylorectomy done for distal gastric ulcers. In one case an early carcinoma was found on microscopic study. Martin advocated gastroenterostomy for duodenal ulcer, but for ulcers located near the pylorus, a Rodman-type resection was used for fear of the existence of malignancy. He recalled that 20 years prior he had observed L. McLane Tiffany of Baltimore, the eighth president, perform a gastroenterostomy for a pyloric lesion, and later the patient died of widespread metastasis. Martin described his technique of performing pylorectomy in which he circumferentially stripped the serosa and muscularis from the pyloric area of the stomach. The mucosa and submucosal pyloric tube was then removed between crushing clamps and the duodenal and gastric ends closed with silk. A posterior gastroenterostomy was then accomplished.

In 1915, Dick Barr of Nashville likewise reported a successful pylorectomy and outlined his technique of suturing the mucosa and submucosa as a separate layer in performing the gastroenteric anastomosis.

John Young Brown of St. Louis, who became the 26th president, was the first to report before the association in 1914 the surgical closure of a perforated duodenal ulcer. Although surgical closure of a gastric ulcer had been attempted by Mikulicz in 1884, the first successful closure of a gastric ulcer was by Ludwig Heusner of Germany in 1892. The first successful closure of a perforated duodenal ulcer was by H. P. Dean of London in 1894. Brown used suture material to close the perforation with reinforcement by an omental graft and the patient survived. He did not perform a posterior gastroenterostomy as previously suggested by both Braun and Moynihan, but did carry out a feeding jejunostomy which was later closed. A posterior gastroenterostomy as definitive treatment for the duodenal ulcer was done at a later date. In discussion, Samuel A. Mixter of Boston reported three patients with perforation who were practically pulseless at the time of operation. Rather than attempt closure he placed a large tube in the perforation which was brought out through the abdominal wall. Fortunately all three patients survived and the fistulas closed spontaneously. Francis Reder of St. Louis discussed the calloused perforated ulcer that could not be surgically closed. He advised drainage of the area with packing, but unfortunately the patient died. A second patient survived after surgical closure. In further discussion, W. P. Carr of Washington, D.C. mentioned two patients with perforation whose tissues were such that he could not obtain a secure closure. He therefore performed a pylorectomy and both patients survived. One of the two was later found to have a distal gastric carcinoma. One patient was constructed with an end-to-end gastroduodenostomy and the other with a gastroenterostomy. These two patients represent the first cases presented before the association with acute perforation treated by primary resection. In 1902, C. B. Keetley of London performed the first primary resection for an acute perforation. Carr also mentioned a case of acute duodenal ulcer perforation that he treated with a gastroenterostomy along with placement of a gauze pack to the area of the perforation.

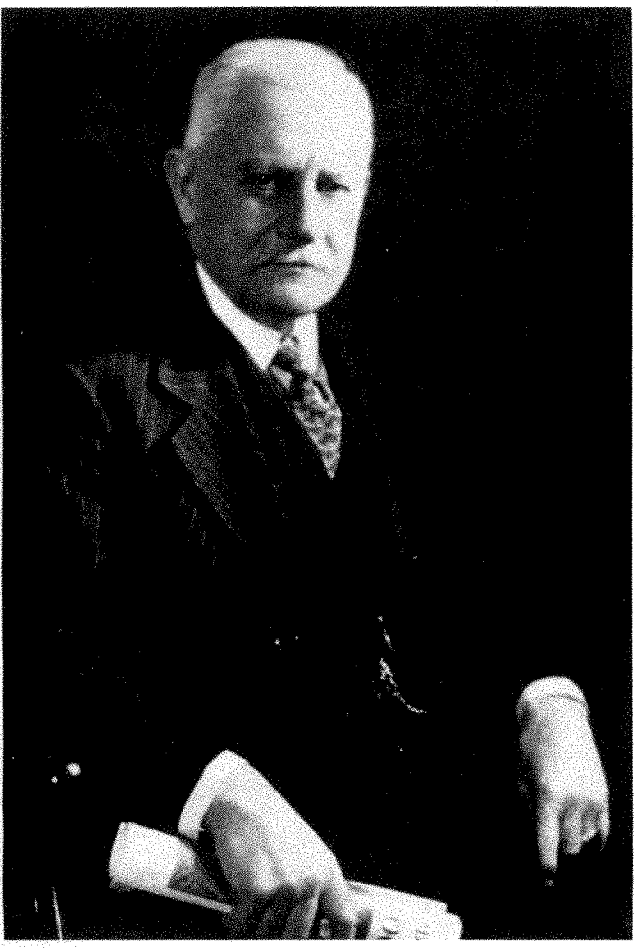

FIG. 3. Randolph Winslow.

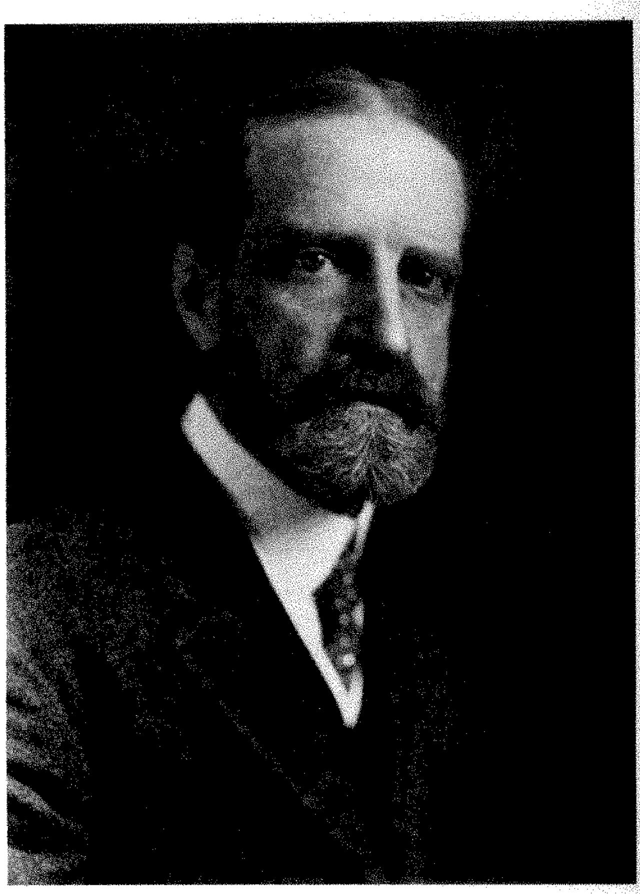

FIG. 4. William L. Rodman.

In 1915, Robert C. Bryan of Richmond described a single case of perforated ulcer involving the proximal jejunum in a patient who had undergone no previous abdominal surgery (Fig. 5). The perforation was located 3 inches distal to the duodenojejunal junction. Surgical closure was impossible; therefore, a piece of omentum was plugged into the opening and the wound was drained. The patient died the next day. The patient had a 2-year history of upper abdominal pain with a diagnosis of stomach ulcer. At the time of operation, Bryan

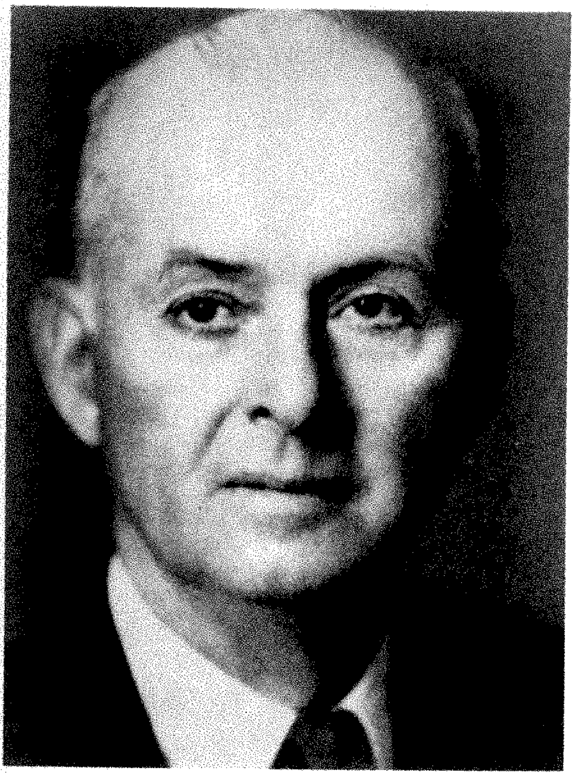

FIG. 5. Robert C. Bryan.

found the duodenum to be scarred and plastered against the posterior parietal peritoneum. The jejunum in the area of the perforation was noted to be white and was thickened. Bryan mentioned that Wagner had reported a perforated ulcer of the jejunum in 1861, 20 years before the first gastroenterostomy was performed. Several years later Edward Richardson of Boston was able to collect from the literature 10 cases of perforated jejunal ulcers without previous abdominal surgery and presented them before the association. Two of the cases had a pyloric and duodenal ulcer. No mention was made in either Bryan's or Richardson's paper of excessive gastric secretion, or the presence of a pancreatic tumor. Unfortunately, Bryan obtained no autopsy material when his patient died.

In 1916, through action by the council, the Southern Surgical and Gynecological Association became the Southern Surgical Association.

Charles N. Cowden of Nashville in 1919 discussed perforations of the gastrointestinal tract. He stated, "Never let the sun shine or set on this condition without an attempt at relief. Operations should be done as expediently as possible, doing only what is necessary, and artistic ideas should be left to less urgent cases." Cowden discussed the history, signs, and symptoms of an acute perforation. He stressed that the pain is usually sudden, sharp, and severe, but made the astute point that when perforation occurs with acute appendicitis, the abdominal pain lessens and the abdominal findings decrease, but the key to diagnosis is the increasing rapidity of the pulse rate. Cowden deplored treating a perforated duodenal ulcer with drainage alone. He emphasized the importance of surgical closure along with reinforcement by omentum or an adjacent loop of bowel. He further stated that in every case of perforation, irrespective of the condition of the patient, there was an absolute indication for immediate operation. When symptoms point rather definitely to perforation but the diagnosis is somewhat in doubt, exploration is safer than delay. He emphasized that shock was no contraindication to exploration.

In 1916, Robert C. Coffey of Portland, Oregon discussed chronic gastric and duodenal ulcers. He believed that 50% of such ulcers should be treated surgically, and posterior gastroenterostomy was his operation of choice. He stated that he had become somewhat annoyed that the procedure was being performed by country general practitioners and general surgeons who had no special training in doing such cases. He emphasized the low mortality with gastroenterostomy performed by members of the Mayo Clinic, the Roosevelt Hospital Staff in New York, and his own private service. Coffey's mortality rate was in the range of 5% among 150 patients. For those ulcers near the pylorus he performed ulcer excision with a Finney pyloroplasty. For gastric ulcers along the lesser curvature he preferred a Balfour cautery destruction plus either pyloroplasty or gastroenterostomy. For large stomach ulcers either a pyloroplasty or gastroenterostomy was done followed by treatment with a medical regimen. If this method failed, some type of gastric resection was then done. Coffey strongly believed that with ulcers in the pyloric area one should be suspicious of carcinoma, and a pylorectomy should be performed. In discussion, J. M. T. Finney, Sr., of Baltimore, the 25th president, described his wide experience with pyloroplasty (Fig. 6). At the 1902 meeting of the American Surgical Association Finney first outlined the technique of his operation. At the time, Arthur Dean Bevin of Chicago told Finney that the operation was too difficult technically and that Finney was straining at a gnat and trying to swallow a camel.

A few years later at the Southern Surgical Association, Charles H. Mayo of Rochester, Minnesota mentioned a large series of both gastric and duodenal ulcers and stated that gastroenterostomy was the treatment of choice at the Mayo Clinic irrespective of the location of the ulcer. However, if there was suspicion of cancer present in the margin of a gastric ulcer, the Mayo Clinic surgeons combined cautery destruction with gastroenterostomy. In a lively discussion Finney stated, "Gastroenterostomy, like an amputation is always the confession of defeat. Gastroenterostomy is never an operation of choice but always an operation of necessity." (With Dr. Finney, Sr.'s great interest in pyloroplasty, it is noteworthy that many years later his son, George, the 72nd president, read a paper on his experiences with duodenal ulcer surgery and did not mention pyloroplasty.)

At this same meeting, Edward P. Richardson of Boston presented a paper on acute and subacute perforations of the stomach and duodenum from the Massachusetts General Hospital. He mentioned that in the years from 1896 to 1900 there was a 75% mortality rate among patients with a perforated gastric ulcer and a 100% mortality rate among the duodenal ulcer perforations. In contrast, from 1911 to 1915 there was a 57% mortality rate among the gastric ulcer group and only a 20.8% mortality rate among duodenal ulcer perforations. He stated that advanced age was an important factor in mortality and that the degree of intra-abdominal spillage was greater in gastric ulcer patients. Packing and drainage without suture as used in the earlier cases contributed greatly to mortality.

Stuart McGuire of Richmond, the 22nd president and son of Hunter Holmes McGuire, the second president, gave a delightful and comprehensive review of duodenal fistula in 1919. He mentioned that such fistulas may follow a right nephrectomy, biliary and gastric operations, and inadvertent injury to the duodenum. He mentioned the excessive fluid loss, skin excoriation, weight loss, and malnutrition that occur as complications. He believed that with duodenal injury occurring during a right nephrectomy the fistula could usually be closed as it was located on the posterior duodenal wall. However, with a duodenal fistula following biliary or gastric surgery, the fistulous opening was usually on the anterior wall, and if such a fistula developed after surgery it did not render itself to direct suture. He suggested that in certain cases of persistent fistula, posterior gastroenterostomy and pyloric occlusion as advocated by Deaver was a reasonable method of treatment. McGuire mentioned a single case in which a fistula developed after biliary tract surgery and there were such extensive adhesions in the upper abdomen that he could not perform gastroenterostomy and an exclusion procedure. He treated the patient with a feeding jejunostomy and recovery eventually took place.

Throughout the 1920s and into the late 1930s, simple gastroenterostomy remained the preferred treatment of duodenal ulcer by many American surgeons. However, for treatment of gastric ulcers, many surgeons began to advocate some type of resection with ulcer excision for fear of the existence of malignancy or for fear of a benign ulcer undergoing malignant transformation.

In 1920, J. Shelton Horsley of Richmond presented the first paper before the association on marginal ulcer following gastroenterostomy. Both Horsley and Donald Balfour of Minnesota observed that gastroenterostomy was more frequently followed by marginal ulceration if the patient had a patent pylorus and an open duodenal outflow tract. Gastrojejunostomy gave better results if there was a cicatrical obstruction at the pyloric canal, as pyloric stenosis prevented the lowering of alkalinity of the duodenal contents and the gastroenteric stoma was more adequately bathed with biliary and pancreatic contents. Horsley reasoned that, instead of magnifying the importance of technical errors of the operation in promoting recurrent ulcers, one should justly regard the violation of broad physiologic principles as the cause of jejunal ulcer. Horsley expressed dissatisfaction with the results of gastrojejunostomy for both gastric and duodenal ulcer, and cited the work of Frank Smythe of the Augustana Hospital in Chicago. Smythe observed that among 273 patients with a gastroenterostomy only 20.9% were symptom free. In treatment of a marginal ulcer after gastroenterostomy, Horsley advised takedown of the gastroenterostomy, closure of the jejunum, closure of the stomach, and the addition of a pyloroplasty. He further stated that it seemed logical to conclude that if a pyloroplasty is the proper treatment for the cure of a jejunal ulcer after gastroenterostomy, then

FIG. 6. J. M. T. Finney.

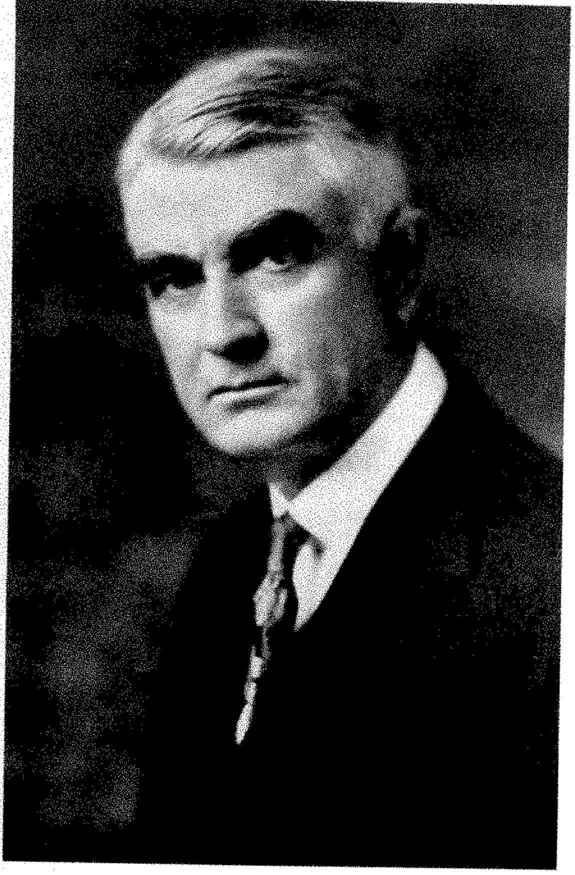

FIG. 7. William J. Mayo.

pyloroplasty in the first place should have been excellent prophylactic treatment for jejunal ulcer. He expressed his recent interest in pyloroplasty in which he excised a longitudinal ellipse of the anterior pyloroduodenal canal and closed it in a transverse fashion. Twenty-four of these procedures were reported, most being done for primary ulcer disease. Horsley further mentioned that a long interval may elapse before the development of a marginal ulcer. He stated, "It is only after continual perversion of the physiology of the jejunum that nature begins to protest." Will Mayo of Rochester in discussion believed that most recurrent ulcers after gastrojejunostomy were due to a combination of faulty operative technique and the use of nonabsorbable suture material. (Fig. 7) However, in his own experience only 1.2% of patients had a recurrence after gastroenterostomy.

That same year, Charles H. Mayo of Rochester presented a paper on gastric and duodenal ulcer and stated that gastroenterostomy was still the treatment of choice at the Mayo Clinic, irrespective of the location of the ulcer. In an analysis of 647 operations for ulcer of the stomach, the average mortality rate after gastroenterostomy was 3.2%, which was more than double the average mortality rate in 2734 operations performed during the same period for duodenal ulcer.

At the 1921 meeting, George Crile, Sr. of the Cleveland Clinic was beginning to show an interest in gastric resection for both gastric and duodenal ulcer. However, he still largely favored simple gastroenterostomy and advised resection as a secondary operation if gastroenterostomy failed. He also was beginning to show an interest in pyloroplasty over gastrojejunostomy.

During the next few years Crile's enthusiasm for gastric resection over pyloroplasty increased. He presented an interesting analogy between hyperthyroidism and peptic ulcer. Crile stated that hypersecretion of acid was a central figure if not the cause of peptic ulcer and that hypersecretion of thyroid hormone was the central feature if not the actual cause of hyperthyroidism. Both conditions flourish in an atmosphere of stress and striving. Both are induced and augmented by overwork and both are improved by a holiday with complete change in environment. Crile further added that both diseases are present among those individuals of keen desires and internal struggles who are carrying the burdens of civilization. Hyperthyroidism may be reduced to normal thyroidism by excision of a sufficient amount of the secreting gland, and hyperacidity is reduced by excision of a sufficient portion of the acid secreting area of the stomach. He further stated that arterial ligation gave temporary relief of hyperthyroidism as gastroenterostomy sometimes gave only temporary relief from ulcer disease. He remarked that hyperthyroidism had been all but conquered, but the hypersecretion of gastric juice and chronic ulcer had all but defeated the surgeon and the physician. He stated that pyloroplasty in treatment of an ulcer of the lesser gastric curvature would seem analogous to excision of the thymus gland for hyperthyroidism. Thus, he believed that in our surgical thinking we should now start anew, and in the treatment of ulcer disease use gastric resection as practiced by Finisterer, Haberer, and other continental surgeons. He recalled that their mortality rate had been reduced to 2–3% and their results were wholly different from the results of gastroenterostomy and cautery destruction of ulcers. Thus, he believed that the philosophy of the surgical treatment of ulcer should change from local excision or gastric drainage to the control of gastric hypersecretion by resection of a portion of the stomach. Thus, Crile was one of the first surgeons in America to strongly advocate this change in surgical therapy.

A lively discussion followed this 1923 presentation. Both Shelton Horsley of Richmond and William D. Haggard, Jr. of Nashville made pleas for simpler operations. Richard A. Barr of Nashville mentioned that extensive operations done for ulcer by the continental surgeons not only cured the small ulcer but also served to prevent future formation of ulcer. Charles H. Mayo of Rochester said, "I believe few surgeons today would permit the primary resection of a large part of a normal stomach on themselves for the relief of a small duodenal ulcer" (Fig. 8). Donald Balfour of Minnesota remarked that some sort of partial gastrectomy should be done for large ulcers in the distal portion of the stomach, but that for ulcers in the proximal stomach, excision or cautery destruction combined with gastroenterostomy was his method of choice. R. C. Coffey of Portland, Oregon stated that he had obtained good results using pylorectomy after the method of Rodman for distal stomach ulcers. From the overall discussion one gained the impression that members of the Southern Surgical Association were slowly but cautiously beginning to give some thought to the more radical surgical approach to the ulcer problem.

Charles H. Mayo and his son-in-law, Fred W. Rankin of the Mayo Clinic, the latter to become the 50th president, presented the first paper before the association on gastrojejunocolic fistula after gastroenterostomy. They believed that the incidence of this complication varied between 1 and 3%, and they also stated that such cases should not be treated by a massive operation but that the fistula should be taken down, the stomach and colon openings closed, and either a new gastrojejunostomy or a pyloroplasty constructed.

The 1923 meeting contained several more interesting papers on gastroduodenal ulcer disease. J. M. T. Finney, Sr. of Baltimore presented a new method of gastroduodenostomy (end-to-side) along with illustrations. He did the reconstruction following a pylorectomy. In a recent review of the literature he found that Hans Haberer of Germany had described a similar technique. The procedure was applicable for both distally located gastric ulcer and duodenal ulcer. In performing the anastomosis, the cut end of the duodenum was closed and the anastomosis was made between the open cut end of the stomach and the side of the second portion of the duodenum just distal to the duodenal stump closure.

Charles H. Mayo of Rochester also presented his method of gastroduodenostomy following a limited distal resection using a large flap gastroduodenostomy instead of a narrow one as proposed by Finney.

At the same meeting, Donald C. Balfour of Rochester, Minnesota presented a paper entitled "Partial Gastrectomy for Gastrojejunal Ulcer." This represented the first presentation at the Southern Surgical Association advising resection for this complication. Methods previously cited had been operations of lesser extent. Balfour believed that gastrojejunal ulcer following gastroenterostomy took place in about 2% of cases, and that the condition could be treated by one of three methods. Excision of the recurrent ulcer could be done when it was small, and at the same time, the gastroenterostomy could be enlarged. As an alternate, one could take down the gastrojejunostomy, excise the recurrent ulcer, and close the openings in the stomach and jejunum and perform a pyloroplasty. Also, another method was to remove the gastrojejunostomy, excise the recurrent ulcer, and close the opening in the jejunum. This was followed by resection of the pyloric end of the stomach including the old opening of the anastomosis. Restoration of continuity could be done by one of several methods. The latter operation was termed a "partial gastrectomy," and it possessed several advantages. This rather radical approach to the treatment of marginal ulcer was certainly a deviation from the method of treating a primary ulcer by gastrojejunostomy alone or by cautery destruction with gastrojejunostomy. Eleven years later in 1934, Balfour presented another paper on jejunal ulcer and strongly favored gastric resection.

FIG. 8. Charles H. Mayo.

At the 1924 meeting, Frank K. Boland of Atlanta, later the 47th president, presented his experience with simple closure of acute perforated duodenal ulcer

FIG. 9. William Haggard, Jr.

among seven patients. He stressed the difficulty at times in making the correct diagnosis and mentioned that ulcer perforation could be confused with acute appendicitis. His treatment of choice was immediate laparotomy with closure of the perforation using a pursestring suture. If the ulcer was amendable to excision this was carried out at the same time. He drained the right upper quadrant as well as the pelvis, but did not perform a concomitant gastrojejunostomy. In discussion, Harley Shands of Jackson, Mississippi remarked that he added a gastrojejunostomy to simple closure only if closure appeared to compromise the duodenal opening. Shelton Horsley of Richmond remarked that he added a pyloroplasty in some cases, and if he used a gastrojejunostomy he would always put a ligature around the pylorus. He believed that the ligature placed the duodenum at rest and promoted healing. Dick Barr of Nashville gave a delightful discussion, as he always did at the Southern Surgical Association, and he would frequently challenge the Mayo brothers concerning their results with simple gastrojejunostomy. Barr stated that he had had poor results with gastrojejunostomy for treatment of a nonperforated ulcer, and therefore, he could see no advantage to adding a drainage operation to closure of a perforated duodenal ulcer.

In 1926, W. D. Haggard, Jr. of Nashville, the 30th president, discussed "Resection of the Stomach and Duodenum for Ulcer" (Fig. 9). Haggard mentioned that ulcer surgery was now going through an interesting period, and that the best method of surgical cure was open to question. He mentioned that the conservative attitude of American surgeons was being attacked, and recalled that on a recent visit to the surgical clinics of Europe he had observed radical operations being done on the stomach for ulcer disease. He believed that pyloroplasty as currently advocated by some American surgeons was not an ideal operation, but stated that he was not ready to give up on gastroenterostomy entirely. He was, however, beginning to give serious consideration to performing distal gastric resection with a Billroth I reconstruction for distally located gastric ulcers. A larger resection was advocated with a Polya-Balfour anastomosis for more proximally located gastric ulcers. Haggard stressed that 15% of gastric ulcers had been shown to be microscopically malignant, and he believed that many benign gastric ulcers underwent malignant changes. He also stated that the percentage of gastric ulcers currently being dealt with by resection at the Mayo Clinic was now up to 16.4%. He also mentioned sleeve or segmental resection of the stomach for midbody lesions with a cure being obtained in as high as 95.2% of cases. Haggard also advised excision of all bleeding ulcers of the duodenum and believed that as his experience increased he would come to resect more and more duodenal ulcers. He mentioned that George Crile, Sr. of Cleveland, John B. Deaver of Philadelphia, and A. A. Berg of New York were beginning to favor gastric resection.

In discussion of Haggard's paper, J. A. Crisler of Memphis, a strong advocate of gastrojejunostomy, stated, "I hope that dear splendid Dr. Haggard will not use his oratorical prowess to such an extent as to condemn this very useful and necessary operation. He has that splendid way about him of being able to make one believe that black is white and vice versa. It is hoped that he will spare those of us who have had many reasons to become endeared to this particular surgical procedure the privilege of continuing the same without his erstwhile condemnation."

In 1926, E. Starr Judd and Gunther W. Nagel of Rochester, Minnesota read a paper entitled "Duodenitis." They had encountered patients with ulcer-like pain, but who had no demonstrable duodenal ulcer crater or deformity. In those patients refractory to medical management, the authors advised an operation consisting of opening the first portion of the duodenum and distal stomach with excision of the diseased mucosa. The anterior portion of the pyloric sphincter was cut and the anterior gastric and duodenal walls were then sutured together. If the inflammatory process was too extensive, a gastroenterostomy was the treatment of choice. At the Mayo Clinic, 94% of such patients obtained an excellent result.

During the late 1920s and into the late 1930s, discussions on ulcer disease continued with many members still favoring gastroenterostomy or pyloroplasty for chronic duodenal ulcer. Some type of resection with ulcer excision or cautery destruction was being increasingly advocated for gastric ulcer. Gastric resection was also being increasingly advocated as the operation of choice to correct jejunal ulcer and lesser operations as excision, closure of the stomach, and closure of the jejunum were being abandoned. A few interesting comments from papers presented during the late 1920s and 1930s are listed below.

J. Tate Mason of Seattle reported a 4.5% mortality rate with gastrojejunostomy among 90 patients. The results were unsatisfactory in only 12.8%. Robert C. Coffey of Portland, Oregon stated that there was no operation in abdominal surgery that gave more satisfactory results than gastroenterostomy. John B. Deaver of Philadelphia still believed that conservative operations were the treatment of choice, but that he occasionally did a pylorectomy for an ulcer in a mobile duodenum or when the ulcer was located in the pyloric area. D. F. Jones of Boston read a letter before the association from a surgical friend who had recently reported 221 subtotal gastrectomies for duodenal ulcer with 95% good results. The friend stated that there was no satisfaction or convenience from gastroenterostomy or from other types of pyloroplasty. The friend also mentioned 25,000 gastrectomies reported in a survey from Vienna, which encompassed a collected series of operations throughout various European countries. The incidence of marginal ulcer was less than 0.5%, but recurrences were 20–25% among those patients who received gastroenterostomy alone. The friend also told Jones that subtotal gastric resection for duodenal ulcer had been the most satisfactory operation in the upper abdomen performed in his institution. (It was believed that this letter was composed by A. A. Berg of the Mt. Sinai Hospital in New York.) Donald Balfour of Rochester, Minnesota disagreed with the letter and believed that there would be too many deaths from such a radical operation. Urban Maes of New Orleans stated that gastroenterostomy still gave excellent results for duodenal ulcer and slightly less good results for gastric ulcer. Frederic W. Bancroft of New York described his operation of pyloric exclusion and distal resection for duodenal ulcer. This was a modification of the Devine operation, and was suggested to Bancroft by Lewis Gregory Cole. It had the advantage of coring out the antral mucosa, and Bancroft believed that it had merit over the standard gastric resection. Frank Lahey of Boston expressed dissatisfaction with gastroenterostomy, and mentioned that the incidence of stomal ulcer was 16–24%. Lahey was now giving more and more attention to gastric resection for the treatment of ulcer disease.

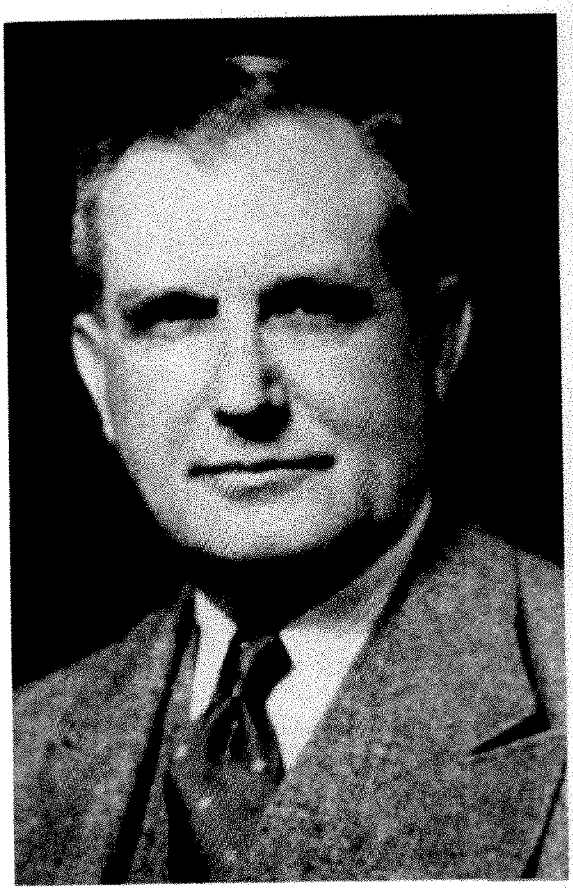

FIG. 10. Roy D. McClure.

A major breakthrough occurred at the 1939 meeting when Roy D. McClure of Detroit advocated partial gastric resection for both gastric and duodenal ulcer (Fig. 10). The Henry Ford Hospital group had reduced the mortality rate to 5%, and in their last 53 cases there had been but one death. McClure was careful to state, however, that the procedure should not be undertaken by the occasional operator. In discussion, Samuel D. Marshall, who had been trained by Roy McClure and who was now at the Lahey Clinic, heartily endorsed high gastric resection for both gastric and duodenal ulcer. He mentioned that 88 consecutive resections had been done at the Lahey Clinic with only one death. Marshall favored an antecolic anastomosis, whereas McClure favored the retrocolic technique.

In 1941, young Waltman Walters of the Mayo Clinic, the son-in-law of Will Mayo, caused an upraising of eyebrows at the Southern Surgical Association when he stated that benign gastric ulcer was now being treated at the clinic by subtotal gastrectomy with a mortality rate of 2.2%. Fewer gastroenterostomies were being done for duodenal ulcer, and local excision or cautery destruction of gastric ulcer combined with gastroenterostomy was being used only in poor-risk patients.

At the same meeting, Arthur W. Allen of Boston and his young guest Claude Welch also endorsed gastric resection and mentioned that it had taken them some years to realize that lesser procedures were associated with a high percentage of failures. They also discussed the Devine and Finisterer exclusion operations and the reasons for their failures. William Francis Reinhoff, Jr. of Baltimore cited 260 consecutive elective operations for duodenal ulcer using subtotal gastrectomy with a failure rate of only 8%.

In 1944, Samuel D. Marshall of the Lahey Clinic stressed the high mortality in performing a one-stage *en bloc* resection for gastrojejunocolic fistula. The mortality rate was 63% among eight patients. He therefore advocated a two-stage procedure and reported a mortality rate of 7.1%. Twelve years later with improvements in anesthesia, surgical techniques, and antibiotic usage, he favored the one-stage *en bloc* operation and reported a respectable mortality rate of 6%.

In 1946, Waltman Walters of Rochester, Minnesota presented the first paper on vagotomy before the association. The presentation was entitled, "Gastric Neurectomy for Gastric and Duodenal Ulceration." Three years earlier, Lester Dragstedt of Chicago had repopularized vagotomy, and preliminary reports had appeared in America by Francis Moore of Boston and Keith Grimson of Durham, North Carolina. Walters mentioned 66 patients and was impressed with the gastric motility disturbances, diarrhea, and emptying problems that occurred. He did not endorse vagotomy as the primary operation for duodenal ulcer, but believed that it might be indicated for the treatment of a recurrent ulcer after adequate gastric resection. He mentioned a 12.5% early recurrence rate with an additional 16% of patients complaining of significant postoperative problems. In subsequent reports and discussions before the association, Walters showed very little enthusiasm for vagotomy with drainage except in selected circumstances. He actually stated that vagotomy with gastroenterostomy probably had no advantage over gastroenterostomy alone. Frank Lahey of Boston advised caution with the procedure and likewise compared it with gastroenterostomy.

On the other hand, Keith Grimson of Duke, in his presentations and discussions during the 1940s and early 1950s, expressed enthusiasm for vagotomy and gastroenterostomy, and over the years reported 335 patients with 91.4% obtaining satisfactory results. At times rather heated discussions occurred at the Southern Surgical Association between the advocates of high subtotal gastrectomy and those who favored vagotomy with drainage for duodenal ulcer. At one of the national meetings one renowned surgeon went so far as to state that perhaps a moratorium should be declared concerning vagotomy. It was the consensus of opinion among most surgeons that vagotomy and drainage should not be used in the treatment of gastric ulcer and that subtotal gastrectomy with removal of the ulcer was the treatment of choice.

Michael E. DeBakey and the group in Houston were largely responsible for popularizing definitive operation in America for selected cases of acute duodenal ulcer perforation, a method that had been used on the European continent since the first part of this century. Beginning in 1952, the Houston group showed in several papers that subtotal gastrectomy and later vagotomy/antrectomy in selected cases could be performed with a very low mortality and with excellent long-term results. DeBakey later mentioned 535 primary resections with a mortality rate of only 2.2%.

John M. Emmett of Clifton Forge, Virginia gave two separate discussions on gastric resection for acute duodenal ulcer perforation. He cited 76 patients with no mortality and a 5% recurrence rate. The patients were selected but he was performing a primary resection in 91% of his cases.

It is of interest that in 1955, Benjamin F. Byrd of Nashville reported 191 patients with a perforated duodenal ulcer treated by simple closure at the Vanderbilt University Hospital over a 25-year period with an acceptable mortality rate of only 7%. At the time of the study only one definitive operation had been done at Vanderbilt for a perforated duodenal ulcer. Henry Cave of the Roosevelt Hospital in New York also advocated primary resection in selected cases of acute duodenal ulcer perforation.

During the 1950s there was a gradual but increasing interest in vagotomy for duodenal ulcer due to the tireless efforts of Lester Dragstedt of Chicago (Fig. 11). Dragstedt weathered rather severe criticism in the early years from many of his colleagues regarding vagotomy.

In 1952, Leonard W. Edwards of Nashville presented the first paper before the association on truncal vagotomy with antrectomy for treatment of duodenal ulcer (Fig. 12). Thirty-four cases were described with a follow-up extending to 6 years. Edwards had performed the first such operation in January 1947, unaware that Reginald Smithwick of Boston had performed a similar operation in October 1946. Smithwick presented his paper before the American Surgical Association in 1951. In discussion of Edwards' paper, Frank Lahey stated, "In the past few years vagotomy has been frequently discussed often with too much pride and equally too much prejudice, and one can make bad friends depending on which side you happen to place yourself regarding vagotomy." Lahey favored resection but warned about the complications that can occur when the duodenum is severely diseased.

During the next two decades, H. William Scott, Jr. with the Vanderbilt/St. Thomas surgical groups presented several additional papers on vagotomy/antrectomy, and in a substantial number of cases reported an ulcer recurrence of less than 1%, and an elective mortality rate of 1.5% (Fig. 13). They stressed the combined operation was suitable for all complications of duodenal ulcer, and it could be done with safety except in high-risk patients and in those with an intense inflammatory process about the duodenum.

Much discussion was given to this operation throughout the late 1950s, 1960s, and early 1970s, and the procedure was highly endorsed by such members as Robert Coffey of Washington, D.C., the 81st president, George Crile, Jr. of Cleveland, Walter Burdette of Salt Lake City, George Jordan of Houston, Joe Hamilton of Louisville, Julian Quattlebaum, Sr. of Savannah, and others. One dissenting remark that stands out was made by Mark Ravitch, at the time I believe from Chicago. He had the audacity to term the operation, "A ritual circumcision of the pylorus." Most surgeons came to acknowledge that vagotomy/antrectomy was the best operation to prevent recurrent ulcer. However, it was believed that vagotomy with drainage was a safer operation in inexperienced hands, among high-risk patients, and when an intense inflammatory process existed in the duodenum. Both procedures were now being widely used throughout the world, and case selection was stressed in choosing between the two operations. During this period one could see a gradual trend away from high subtotal resection for duodenal ulcer and a slow gradual acceptance of the two more conservative procedures.

In 1952, Isidore Ravdin of Philadelphia in discussing gastric ulcer and gastric carcinoma made a plea for immediate operation in every patient with a gastric ulcer for fear of missing the diagnosis of cancer. Samuel Marshall of Boston advocated an early but not an immediate operation, whereas Frank Lahey stated that he would like to operate on every patient with a gastric ulcer but he could not get the cooperation of his gastroenterologists. You may remember that the distinguished Sarah Jordan was at the gastroenterology helm at the time.

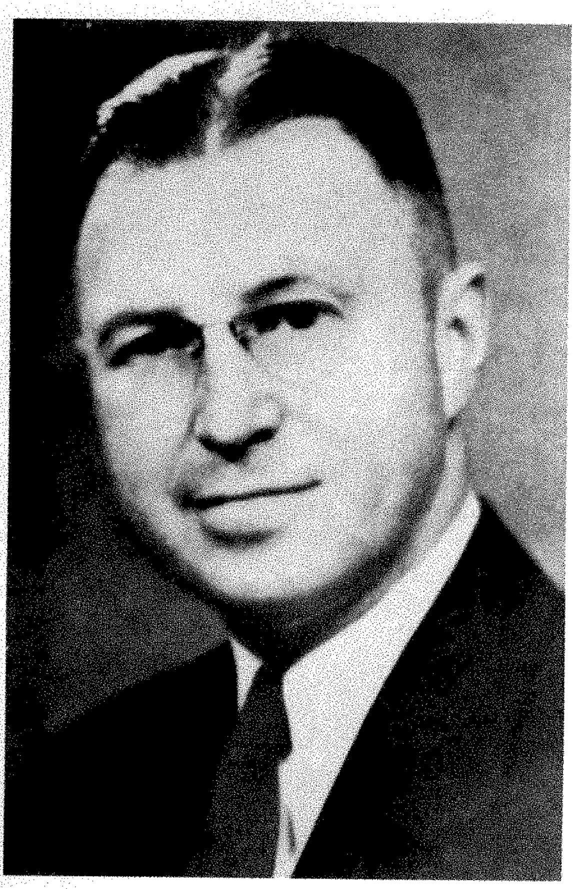
In the 1950s, massive upper gastrointestinal hemorrhage of undetermined origin constituted even a greater challenge than it does today as routine endoscopy was not available. Howard Gray of the Mayo Clinic believed that when the point of bleeding was undetermined, it was best to proceed with a high-blind subtotal gastric resection. James A. Kirtley, later the 77th president, and Douglas Riddell of Nashville advocated a generous gastrostomy as originally described by Frank Spencer, then of Baltimore, in order to search for the bleeding source.

FIG. 11. Lester Dragstedt.

About this time a more aggressive surgical approach was advocated for the treatment of the massively bleeding peptic ulcer. The problem was discussed in depth by George Mixter and William Hinton of the Bellevue Hospital in New York. Hinton described a most interesting patient who bled massively after a subtotal gastrectomy done for a bleeding duodenal ulcer. Over a 10-day period 118 units of blood were given. A transthoracic vagotomy was then carried out with prompt arrest of bleeding.

At the 1957 meeting, Isidore Cohn, Jr. of Louisiana State University, later the 97th president, made a significant contribution when he discussed giant gastric ulcers. He showed that only 8.6% of such ulcers at the Charity Hospital were malignant, whereas it had been taught that up to 80% of giant ulcers contained carcinoma. In a collected series of 613 giant gastric ulcers, Cohn found 71% to be benign. Waltman Walters in discussion believed that the larger the ulcer, the more prone it was to be a cancer.

William O. Barnett of Jackson, Mississippi in 1963 showed the value of a Roux-en-Y limb when faced with a difficult duodenal stump closure following gastric resection. Discussants reminded Barnett that when a severe inflammatory process was found in the duodenum



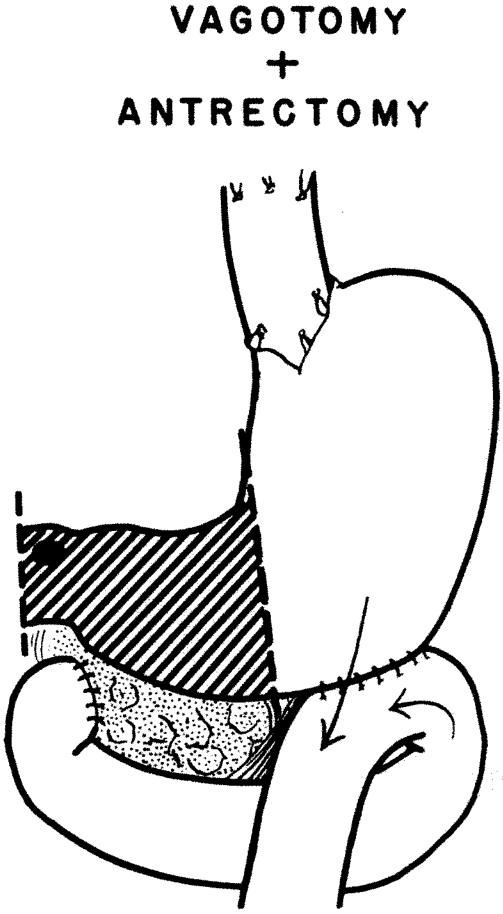


FIG. 12. Leonard Wright Edwards.

one should resort to a lesser procedure and not commit themselves to a gastric resection. Barnett responded by saying that severe pathology in the duodenum could not always be appreciated until one had divided the stomach and committed oneself.

During the 1960s four papers were presented on gastric freezing for the treatment of both duodenal and gastric ulcer by William Scott of Nashville, the 90th president, Raleigh White of Temple, Texas, Curtis Artz of Jackson, Mississippi, and William Shingleton of Duke. Each author cited early good results but mentioned the significant complications and later failures that followed this method. Never again was gastric freezing a topic for discussion at the Southern Surgical Association.

Claude Welch of the Massachusetts General Hospital in 1966 presented a paper on anastomotic ulceration. Welch believed that the ideal operation to prevent recurrence was vagotomy and a partial resection, and that when marginal ulceration followed a lesser procedure such as vagotomy and drainage, revagotomy and resection was the procedure of choice.

The surgical management of massive bleeding from peptic ulcer and bleeding from superficial gastric erosions were frequent topics of discussion during the 1960s. However, the first paper on postoperative gastric hemorrhage after operation on organs other than the stomach was presented by Kennedy Gilchrist of Chicago in 1957. This presentation aroused much interest among the members.

J. Englebert Dunphy of Portland, Oregon in 1964 described 239 patients with massive bleeding from duodenal ulcer. He believed that the best results were obtained with vagotomy and pyloroplasty and ligation of the bleeding vessel. There were others who advocated radical gastric resection or vagotomy with antrectomy.

In a 1968 paper, James Kirtley of Nashville discussed the management of superficial gastric ulcerations and believed that the best results were obtained with vagotomy and pyloroplasty and undersewing of the bleeding points. William Scott of Nashville made a pertinent statement when he said that he did not know what was the proper operation for such bleeding and that cases must be carefully individualized.

In 1971, Isidore Cohn and Carter Nance of New Orleans studied 768 patients with upper gastrointestinal bleeding who underwent operation at the Charity Hospital over a 5-year period. The overall mortality rate was 29% and was 44% for patients over age 60 years. The operative mortality rate for emergency operation was 31%. The authors believed that they had not been aggressive enough in advising early operations on massively bleeding patients. Several discussants emphasized the hazards of delayed operation, but there was no agreement among the discussants as to the best operative procedure to control hemorrhage.

A few highlights of papers presented between 1970 and 1980 included the experience of Theodor Drapanas of Tulane University at New Orleans, who discussed the surgical management of acute gastric mucosal hemorrhage. Drapanas studied 31 patients with near exsanguinating bleeding from superficial gastric erosions. He observed that among 19 patients treated by vagotomy and resection, there was no incidence of recurrent hemorrhage. However, among 10 patients who underwent a subtotal gastric resection without vagotomy, several rebled. The incidence of rebleeding in those patients who did not receive vagotomy was 50%. His experimental work showed that vagotomy produced a salutary effect in controlling mucosal bleeding by the opening of arterial venous shunts in the submucosa and by depleting vasoactive amines from the mast cells in the mucosa. Bradley Aust of San Antonio used extensive devascularization of the stomach to arrest gastric mucosal hemorrhage.

The management of postoperative alkaline reflux gastritis following operations on the stomach and duodenum was beginning to attract attention during the 1970s. William McCune of Washington, D.C. presented a most interesting paper concerning 11 patients with severe reflux that followed either vagotomy with drainage or vagotomy with resection. The importance of endoscopy with biopsy was emphasized in making the diagnosis. Each of the 11 patients was treated with a Roux-en-Y reconstruction and a hemigastrectomy. If the previous operation had been only vagotomy and pyloroplasty, a hemigastrectomy was added and very satisfactory results were obtained.

In 1973, Theodore Drapanas of New Orleans in discussing postoperative alkaline reflux gastritis cited 24 patients who were markedly benefited with a Roux-en-Y diversion or a Tanner-19 loop. A decade later Wallace Ritchie of Temple University in Philadelphia gave a scholarly presentation on the subject and attempted to outline objective preoperative data that was important in selecting candidates for operation.

During the 1970s adequate subtotal gastric resection for treatment of duodenal ulcer was no longer a topic of discussion at the Southern Surgical Association. Many surgical giants now believed that this operation would soon be of historical interest only for treatment of such ulcers.

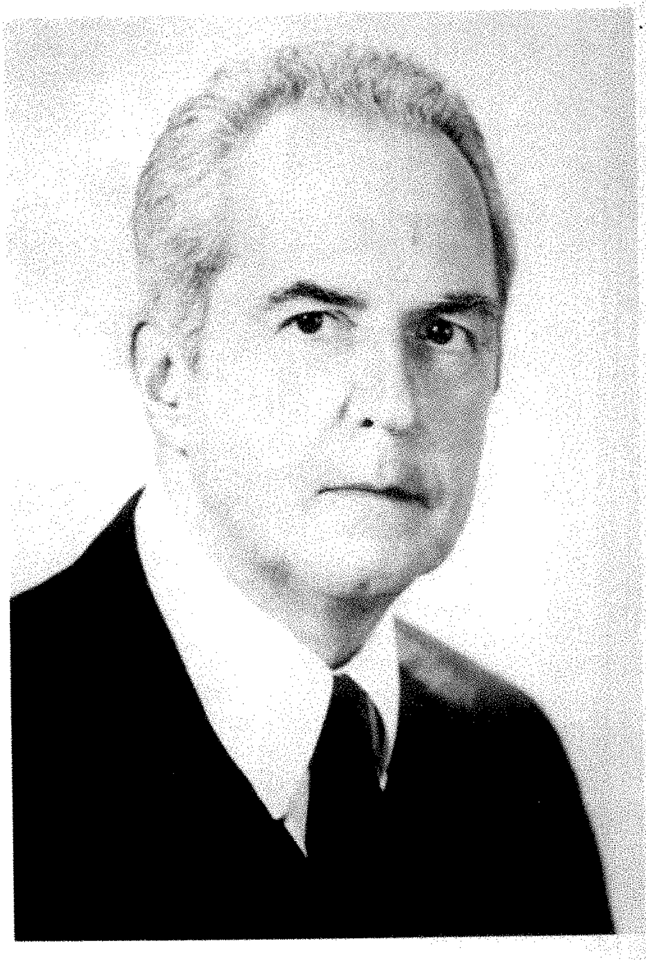

FIG. 13. H. William Scott, Jr.

In 1973, George Hallenbeck of Birmingham was the first to discuss proximal gastric vagotomy. His was principally an experimental paper, and Hallenbeck showed that histamine and pepsin-induced secretion of hydrochloric acid were reduced with the operation and he confirmed the fact that gastric emptying was essentially unchanged following the procedure.

In 1975, Paul H. Jordan, Jr. of Houston presented his first paper on parietal cell vagotomy and believed that from a short-term study the operation was superior to selective vagotomy/antrectomy because of its lower rate of postoperative complications of dumping, diarrhea, and reflux. He suggested that perhaps parietal cell vagotomy might become the elective treatment of choice for duodenal ulcer but further study was necessary. Three years later before the association Jordan stated that there was now a gradual trend in America to use parietal cell vagotomy over gastric resectional procedures for treatment of the intractable duodenal ulcer. Again in 1986 he presented a splendid prospective randomized study in-

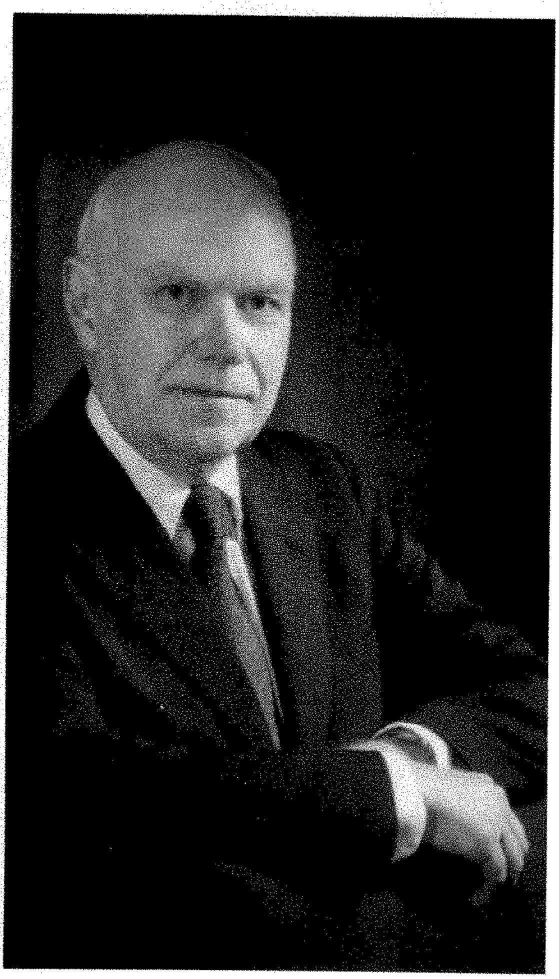

FIG. 14. John L. Sawyers, president at the centennial meeting.

volving 200 patients treated electively with either parietal cell vagotomy or selective vagotomy/antrectomy with a 10-year follow-up. This represented a monumental piece of work and rivaled any of the papers on the subject from Copenhagen and Leeds. He reported only a 6% recurrent ulcer rate using parietal vagotomy for duodenal ulcer, and long-term symptoms of dumping, diarrhea, and reflux were negligible. There were no recurrent ulcers in the selective vagotomy/antrectomy group, but significant symptoms of dumping, diarrhea, and reflux were encountered. He also believed that parietal vagotomy might be acceptable for a type I gastric ulcer, but was unacceptable for the treatment of a pyloric and prepyloric ulcer. In 1976, John Sawyers of Nashville presented 21 patients with acute duodenal ulcer perforation treated by closure and parietal vagotomy with no mortality. He believed that the procedure represented a satisfactory compromise between simple closure alone, which did not insure against recurrence, and a definitive operation as vagotomy with resection or drainage, which would subject some patients who would have no further problems after simple closure to long-range complications of dumping and diarrhea.

The 1975 meeting included a paper by Patrick O'Leary, Edward Woodward, and Lester Dragstedt of Gainesville, Florida in which they cited 455 patients who had undergone vagotomy and drainage for duodenal ulcer over a long-range period with an ulcer recurrence rate of 5.8%. Both Lynwood Herrington, Jr. of Nashville and Ward Griffen of Lexington informed the authors that 24% of patients in the Florida study had been lost to follow-up, and that perhaps their recurrences might have been as high as Griffen's and Herrington's if all patients had been followed. Griffen had previously reported a recurrence rate of 25% among 112 patients.

James Thompson of Galveston presented his first paper before the association as a new member in 1975. He spoke eloquently on the effects of gastrin and gastric acid secretion after five different operations for duodenal ulcer. He showed that vagotomy with antrectomy was the most effective operation in lowering gastric secretion. He was so happy over being elected to fellowship in the association that after his presentation he screamed aloud, thanked the association, raised his hands over his head, and gave a real rebel yell. (Thompson states that he was no relation to James E. Thompson of Galveston, the 32nd president. Jim, however, further mentions that he generally does not object to the fact that many people think James E. Thompson was his grandfather. Isidore Ravdin always thought so and Jim believes that is the reason he became chief surgical resident at the University of Pennsylvania.)

Only three papers have been presented before the association addressing the Zollinger–Ellison syndrome. At the 1978 meeting, Charles Davis and John Vansant of Norfolk cited the fascinating case of a patient who underwent total gastrectomy but later developed liver metastasis which spontaneously regressed. This was confirmed by appropriate scanning and at subsequent operation for cholelithiasis. Although serum gastrin levels continue to be elevated in the range of 1000, the patient currently remains asymptomatic after 27 years.

Although many gastric ulcers are currently being treated successfully with the H_2 receptor blockers, R. B. Adkins et al. of Nashville showed at the 1984 meeting that significant complications can occur while undergoing this medical management (Fig. 14). In a series of 163 patients, it was their opinion that medical therapy had been unduly prolonged, and among patients who came to surgery, 35% were operated on as emergencies for either hemorrhage or perforation. Lesser operations than resection were performed only in high-risk patients. Earlier operative intervention was stressed for gastric ulcer patients, and vagotomy was always added to resection in the presence of a type II (gastric and duodenal ulcers) and type III (pyloric and prepyloric ulcers.)

In 1984, Robert McClelland of Dallas discussed the treatment of recurrent ulcer after various operations on the stomach in which the original vagotomy was incomplete. Irrespective of the original operation for ulcer, if the author could show the presence of an incomplete vagotomy by the sham-feeding peak acid ratio, transthoracic vagotomy was the sole remedial procedure carried out. This rather conservative approach to the problem was in marked contrast to the more radical procedures reported by Claude Welch in former years for the treatment of recurrent ulcer.

In 1985, Hunter McGuire and Shelton Horsley, III of Richmond presented a paper entitled, "The Emergency Operation for Gastric and Duodenal Ulcer in High Risk Patients." The authors stressed the universal decline in the incidence of duodenal ulcer, but noted that they were still seeing patients in the intensive care units who required operation for perforation and bleeding. In such patients the hospital mortality rate was 14.5%. In former years the mortality among better risk patients was 2.7%. This recent increase in mortality was attributed to the presence of multiple organ disease and to the advanced age of the patients.

Summary

By the early part of this century, members of the Southern Surgical Association as well as others began to realize that gastroenterostomy alone was unacceptable for the treatment of gastric ulcer. Ulcer excision and some type of limited resection was advised. At a later date, gastric resection of varying extent, depending on ulcer size and location, became the appropriate treatment for complications of this disease.

For treatment of complications of duodenal ulcer, gastroenterostomy was widely used from the latter part of the 19th century until the late 1930s. Adequate gastric resection slowly but cautiously replaced gastroenterostomy during the 1940s. Vagotomy with drainage and vagotomy with antrectomy slowly developed and replaced adequate resection by the early 1970s. Beginning in the 1970s and extending into the 1980s, fewer duodenal ulcers were seen, and many of those encountered were being adequately managed using the H_2 receptor blockers.

For the intractable duodenal ulcer there is currently an increasing trend to use the less invasive operation of parietal cell vagotomy. Vagotomy with antrectomy for such cases is being used less frequently. Vagotomy and drainage has lost much of its appeal. Lesser procedures have been advocated recently for treatment of marginal ulcer after incomplete vagotomy irrespective of the original operation for ulcer. Massive bleeding and acute perforation are still frequently encountered as complications but are being seen more frequently in elderly high-risk patients, some of whom will tolerate only a lesser procedure as suture ligation, vagotomy with drainage, or simple ulcer closure. It appears that we are now seeing a different duodenal ulcer pattern in the good-risk patient. The ulcers are usually small, less virulent, and less likely to be found penetrating into the pancreas and adjacent organ structures. As Claude Welch so aptly stated recently before the Association, "We are seeing a trend in ulcer surgery that is currently being seen in other areas of surgical endeavors as well." He emphasized that we must be alert to changing disease patterns and adapt our procedures to new requirements.

Acknowledgments

Appreciation is extended to my wife, Mamie Herrington, for her assistance in preparing the manuscript, and also to my secretary, Marge Bartlett and to Mary Teloh, Vanderbilt librarian, for their efforts in assembling the research data. Special recognition is given to Ginna Davidson and Joe Pass from the art and photography departments, St. Thomas Hospital, Nashville, Tennessee.

Plastic Surgery

The First 100 Years of the Southern Surgical Association

M. J. JURKIEWICZ, M.D.

From the Department of Surgery, Emory University School of Medicine, Atlanta, Georgia

WHEN I WAS ASKED to recount the first century of plastic surgery in the Southern Surgical Association (SSA) I accepted with both anticipation and pleasure.

Rather than take a strictly taxonomic approach I will attempt to be more personal. In so doing I wish to make three general points and illustrate these with specific examples within five eras in the past century. (1) It has always been my belief that plastic surgery is part and parcel of general surgery—no more, no less. (2) Beliefs are shaped by our teachers and our traditions. (3) The SSA has had a unique role in the development of plastic surgery.

The belief that plastic surgery is an extension of general surgery clearly did not originate with me. It was impressed upon me in countless ways by my chief at Washington University and Barnes Hospital, Carl A. Moyer. He strongly believed that there is a core of knowledge that all surgeons of whatever discipline should possess. For plastic surgery that core was full training in general surgery. His conviction was born not only of the intuitive faith of surgeons but also his experience at Michigan, Dallas Southwestern, and especially by what he saw and learned at Barnes Hospital in St. Louis.

In 1951 he succeeded Evarts A. Graham as chief of surgery at Barnes Hospital. Graham at that time was the most powerful figure in American surgery. He organized the founding of the American Board of Surgery; he put intellectual spine into the American College of Surgeons; and was chairman of the Board of Regents at the time. Graham, who was appointed as Chairman of the Department of Surgery at Washington University in 1919 while on terminal leave from the Army, appointed Vilray Papin Blair as chief of plastic surgery at Barnes Hospital. Blair in turn, with Graham's help, organized and founded the American Board of Plastic Surgery as a subsidiary board of surgery in 1937.

Some of the men that Graham trained in surgery were picked by Blair to be trained subsequently in plastic surgery. They became the staff at Barnes Hospital, and in Moyer's time the unit led by James Barrett Brown and Louis T. Byars was by reputation the best in the country. Thus, the tradition and the belief that plastic surgery was an extension of general surgery was firmly established at Barnes Hospital at Washington University.

When Blair was speaking throughout the country to gain support for the establishment of the American Board of Plastic Surgery, his message was twofold. Plastic surgery, overall, was ill done because of ill training. The remedy lay in national standards of training and education with a strong background in general surgery. His belief can be summarized in these statements. "I feel strongly, and have so advised all younger men seeking advice, that in its future development plastic surgery will reach its greatest usefulness, its widest application, and bring the greatest personal return when it is studied and practiced as a division of general surgery."[1]

"The term general as applied to a surgeon indicates neither the quality of his work nor the extent of his endeavors, but implies a basic grasp of medical and surgical principles that will permit development along any chosen line of practice, with also a dominant concern for the activities and wellbeing of the body as a living and acting unit."[1]

Presented at the 100th Anniversary Meeting of the Southern Surgical Association, Hot Springs, Virginia, December 6–9, 1987.

The Southern Surgical Association's Unique Role

In the SSA plastic surgery was developed by men who were general surgeons with a special interest in plastic work. Their orientation firmly established the character of the discipline not only within the Association but also nationally. Plastic surgery continues to be strongly identified with general surgery to this day and there is every indication it will continue for the foreseeable future.

That development within the SSA is unique and is directly explicable by the historical events of the time. Many if not most of the founding and early members of the SSA augmented their surgical training by extensive periods of time in the major centers in Europe—London, Vienna, Paris, and Berlin. In each of these centers men such as Czerny, Billroth, Butlin, and Lane were performing operations to correct congenital malformations including cleft lip and palate, skin grafting, flap surgery (as it was understood in those days), and operations for cancer of the head and neck. These skills so learned became part of their general surgical practice upon return to this country.

At the same time that the South was struggling under reconstruction the rest of the country was experiencing a great wave of immigration, much of it from eastern Europe to the northeastern industrial cities. For example, by the turn of the century New York was transformed into a city composed of four-fifths recent immigrants and first generation Americans by the turn of the century. Coming in on this wave of immigration were practictioners of medicine of all sorts including self-designated surgeons of uncertain background and training whose practice was largely that of facial cosmetic surgery, such as it was. Plastic surgery outside the South therefore, developed in a diverse way—from bona fide general surgeons with a specific interest in reconstructive work to outright entrepreneurs, charlatans, and quacks.[2] By contrast, plastic surgery within the SSA developed purely as a general surgical discipline. The leaders of plastic surgery within the SSA were also the very men who played key roles in the establishment of standards of education and training as well as the specialty board of plastic surgery itself.

The Early Years, 1892–1911

The first paper on a plastic surgery subject presented at the SSA was given by William Perrin Nicolson in 1892.[3] In 1894, Nicholson gave a paper on the treatment of congenital nevi (hemangiomas). J. T. Wilson described plastic operations in carcinoma of the breast. In 1894, Long maintained that the three essentials in successful abdominal work were asepsis, hemostasis, and plastic work.[4] By that he meant the use of peritoneal flaps to cover all raw surfaces and to reperitonealize the pelvic floor. He thought that this would prevent morbid adhesions and that such "plastic work contributed materially to asepsis and hemostasis."[4] He acknowledged, however, "Of course, if the case is septic, no amount of plastic work, however beneficial, can do away with the necessity of drainage."[4]

During the next 3 years Edmond Souchon wrote articles on a device to deliver uninterrupted anesthesia in operations on the face and mouth; on the peculiarities of the surgical diseases and injuries of the neck; and on diseases and injuries of the face. He subsequently presented a paper on the diagnosis and operative treatment of tumors of the maxilla. He recognized at this early stage of the development of head and neck cancer surgery the necessity of stabilizing not only the anterior mandible but also of properly reconstructing the geniohyoid mechanism to facilitate breathing and swallowing after extirpation of lesions of the anterior floor of the mouth.

Two papers on cleft lip and palate by James E. Thompson appeared in 1899 and 1911. In that same period there was another paper on the subject by Alex Hugh Ferguson. The operations for repair of both cleft lip and palate were well established by that time and differed little in principle. However, as described by Thompson these operations were exquisitely exacting exercises in "mathematically accurate" measurements as a guide to repair. These articles by Thompson as well as a subsequent one given at the SSA meeting in 1921 were recognized as classics in the field.[5]

The first paper on skin grafting appeared in 1909 by Arthur Scott, who described his method of Thiersch skin grafting and added the technique of meshing the graft. This was less than two decades after Carl Thiersch had presented his technique for cutting sheets of epidermis with a very thin portion of dermis at the German Surgical Congress.

Other contributions in that early period included a paper on hypospadias and epispadias by F. W. Parham, who today is remembered for Parham bands, a method of fixation of long bone fractures. Southgate Leigh described a repair of the base of the bladder by a plastic operation (perineal flap). Alex Ferguson presented a paper on vaginoplasty for congenital abscence of the vagina. Finally, there were two papers on reconstructive rhinoplasty: one by E. Denegre Martin and the other by J. M. T. Finney. In that paper Finney described a novel method of using the little finger to provide bony support for the dorsum of the nose.

Two Future Presidents of the Southern Surgical Association, 1911–1938

The period that roughly included World War I and the years up to World War II was dominated by two

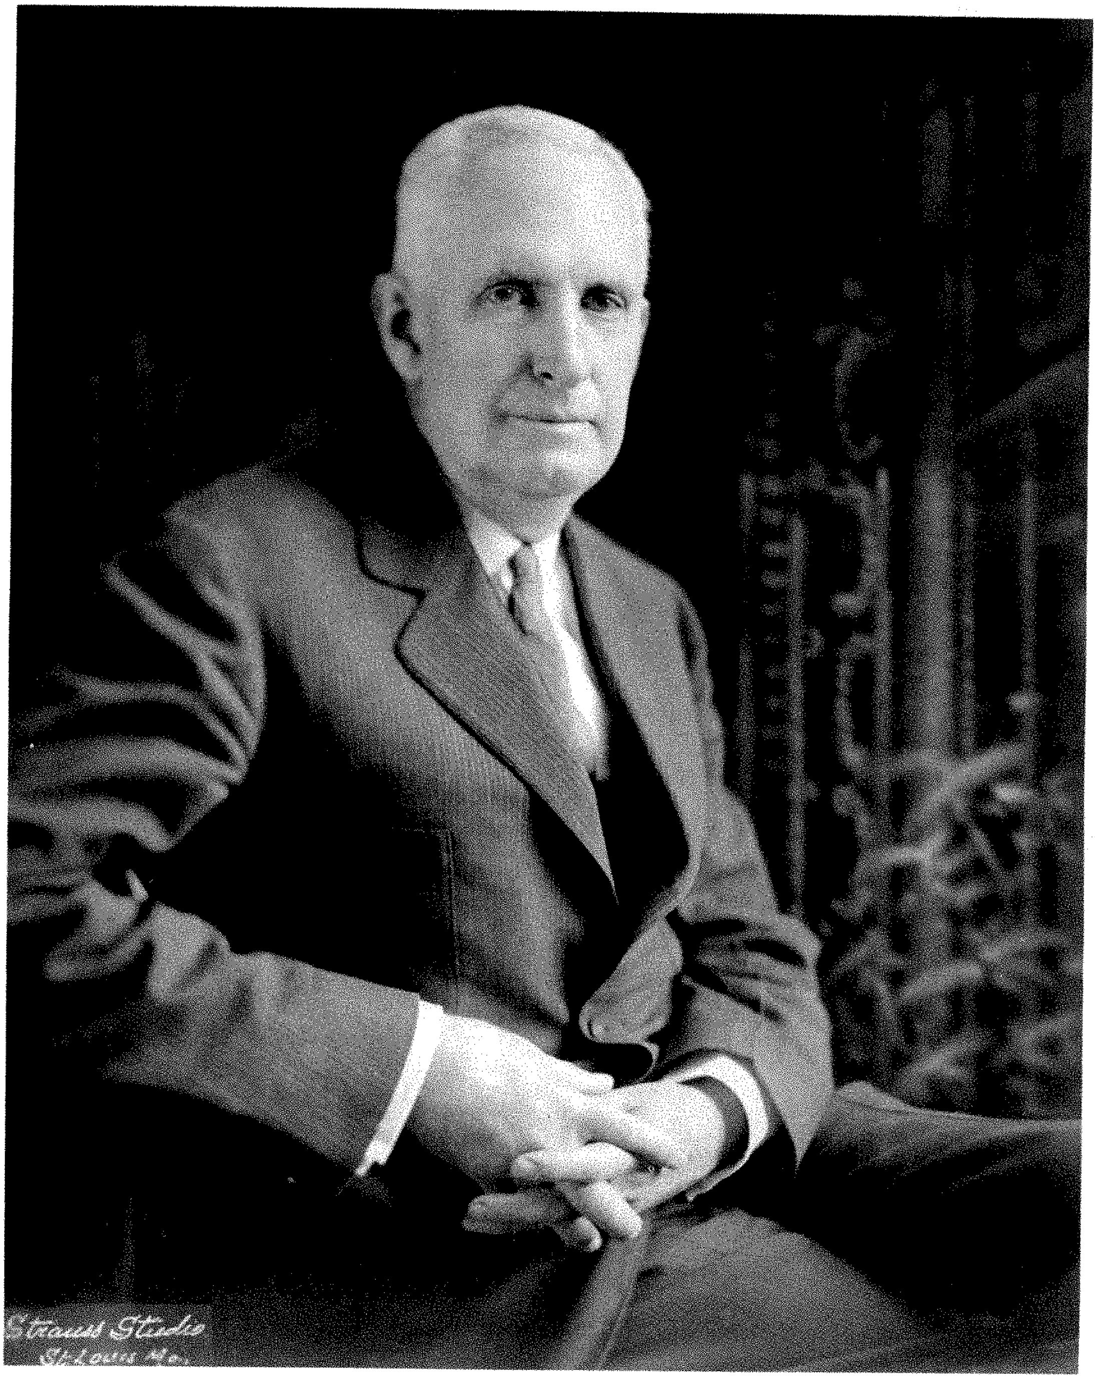

FIG. 1. Vilray Papin Blair.

men: Vilray Papin Blair (1871–1955) (Fig. 1) and John Staige Davis (1872–1946) (Fig. 2). These two men more than all others shaped the destiny of plastic surgery as a specialty. They were the first individuals in this country to devote most, if not all, of their work to plastic surgery. They insisted on identical standards of broad training in general surgery to be followed by training in plastic surgery. Both men were associated with chiefs of surgery who were the dominant figures in American surgery of their time—Halsted and Graham. There is an enduring legacy to American surgery by both Blair and Davis. Blair did so through the men he trained on a distinct and identifiable plastic surgery service at Washington University. Davis participated in the training of a long list of resident house officers in surgery at Hopkins where he was in charge of plastic surgery from 1923 until a brief period prior to his death. Some of these men went on to become chiefs of plastic surgery, for example, Kenneth Pickrell at Duke. Davis, however, was never allowed to establish a distinct specialty service at Hopkins as did Blair at Barnes Hospital.

Both men were enormously influential in the development of reconstructive surgery to the wounded in World War I. Both were instrumental in the establishment of the American Board of Plastic Surgery. Davis was the first chairman and Blair, the first secretary. Blair held that post for many years and the secretary's office remained in St. Louis until 1979 when it was moved to Philadelphia with the American Board of Surgery.

In 1911 Davis presented his first paper to the association, a report on the repair of a cheek defect by a lateral arm flap. His opening remarks in that paper constitute a three paragraph homily that sums up his thinking about the field: "Plastic surgery is attempted by almost everyone who undertakes surgical work and I do not know of any class of cases which is more frequently botched. The scope of this branch of surgery is very broad and includes nearly every region of the body." "A thorough general surgical training is necessary before this work can be properly done. Ingenuity, patience, and constant personal supervision are required."[6]

In 1912, Blair produced a discussion of the paper by Martin on fixation and repair of fractures of the femoral neck. He made his point on plating of fractures in general by citing his broad experience in fractures of the jaw. In 1915 Blair presented his extensive experience on the treatment of cleft lip and palate. In that article he described and illustrated his variation of the cleft lip repair, which became the standard in the country until the late 1950s when it was superseded by the rotation advancement repair described by Millard. Davis presented a paper on the use of free grafts of full thickness skin for the relief of contractures. A hiatus in presentations to the SSA followed because of World War I.

After the entry of the United States into the war, Blair promptly volunteered his services. Commissioned as a captain and assigned to Fort Oglethorpe, Georgia, in June 1917, he was elevated to major later that year and transferred to the Office of the Surgeon General of the Army as Chief of the Section of Oral and Plastic Surgery. Blair was credited not only with the organization of such a service but also the competent care of American soldiers with wounds of the face and jaws so prevalent in the trench warfare of World War I. In this work he was assisted greatly by Dr. Robert Ivy of Philadelphia.

Blair went to England and France in 1918 as chief of the section and took an active part in the battle of Chateau-Thierry and the Argonne. After the war he established centers for oral and plastic surgery throughout the country within Veterans Hospitals. Davis served as Captain in the Medical Corps of the Army from June 1917 to January 1919 and in World War II was a special consultant to the Surgeon General of the Army.

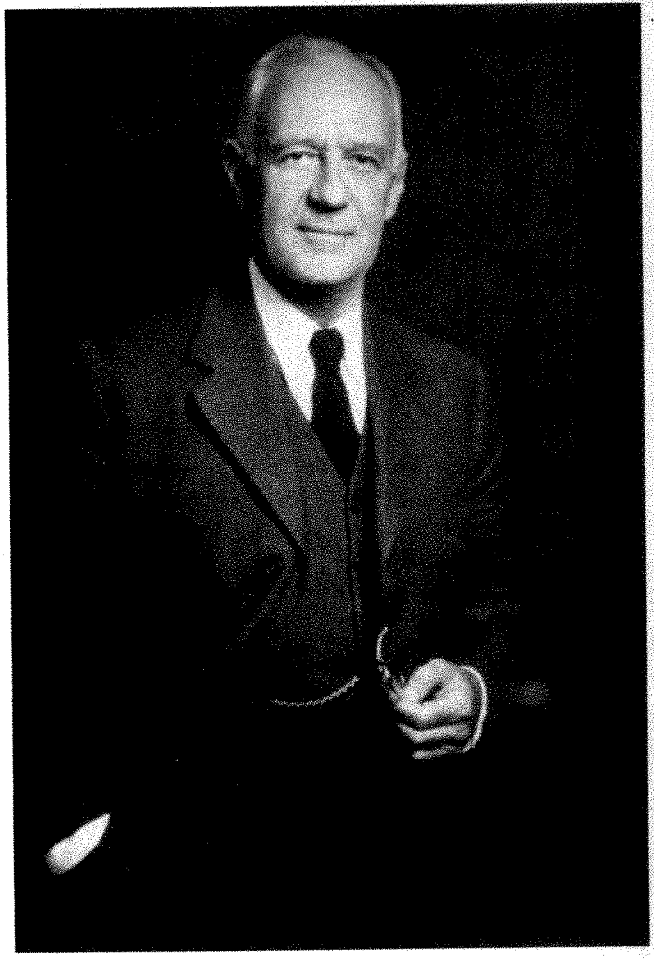

FIG. 2. John Staige Davis.

In 1921, Blair gave a paper on saddle nose of luetic origin. In 1924 he updated his experience on cleft lip repair. In 1926 he described the pathophysiology and psychology of the deformed face. In 1928 and in 1932 he presented two landmark papers on the use of large split skin grafts of intermediate thickness. The first of these was coauthored by James Barrett Brown and the second by Brown and William Hamm. These were telling descriptions of thick split grafts used as broad sheets cut by a freehand knife. These two papers changed forever both the thinking and the techniques of skin grafting. At the 44th annual meeting of the SSA, he presented a paper that described room 8 at Barnes Hospital, the walls of which were painted with animals and scenes from fairy tales designed to allay the fears of children. I am advised that this is one of the very rare instances in a paper that was actually presented at a meeting was not published in the Transactions. Blair's career as a plastic surgeon was capped by election to the presidency of the SSA in 1933.

He retired from active practice in the mid-1940s and died in 1955.

In the year of Blair's presidency, John Staige Davis gave a detailed physiologic study that he carried out with Edward A. Kitlowski on regeneration of nerves in skin grafts and skin flaps. They documented the rate of return of protective sensation in flaps, full thickness, and partial thickness grafts in that order. They also described a dissociation of the sensations of pain, temperature, and touch in all types of transplants and the reappearance of these sensations in the order named.

During those years Davis also presented papers on general plastic surgery, x-ray burns, Z-plasty for the relief of scar contracture, and a description of plastic surgery in World War II. He was elected president of the Association in 1940 and died in 1944, one month after he had been elected to the Board of Regents of the American College of Surgeons.

From 1914 to 1938 these two men, Blair and Davis, presented 19 papers to the Association. In addition, during those roughly three decades six papers were presented by other surgeons interested in the field of plastic surgery. One of these was by J. Shelton Horsley of Richmond who unfortunately died an untimely death in 1940 at the age of 41. Shortly before his death he had been made Professor of Oral and Plastic Surgery at the Medical College of Virginia. His papers before the Association were entitled "Plastic Operations for Acquired Deformities of the Face" and "Surgical Treatment of Extensive Basal Cell Carcinoma." Had he lived he might have rivaled James Barrett Brown who dominated plastic surgery from 1940 until his retirement in 1968.

The Mantle of Leadership Passes, 1938–1963

Over the next 25 years the kingpin of plastic surgery in the SSA and arguably in the country was James Barrett Brown. Trained by Evarts Graham and Vilray Blair, Brown in 1941 was named consultant in plastic surgery to the Surgeon General. This was the same post held by Blair in World War I. Colonel Brown and Major Bricker organized plastic and reconstructive surgical care for the wounded both in the European Theatre of Operations and in the Zone of the Interior. The story of that remarkable achievement was documented in the *Transactions of the Southern Surgical Association* by John Staige Davis. During the war years Brown presented papers on composite grafts to reconstruct the nose as well as various methods of handling war wounds. In 1949 he presented a paper on congenital torticollis; hemangiomas in 1952; penoscrotal skin losses in 1956; and his last paper in 1962 which was on the use of alloplastic substances in reconstructive surgery of the facial skeleton.

Louis T. Byars, an associate of Brown at Barnes Hospital, gave his first paper to the SSA as a coauthor with Blair in 1938. It was a description of a remarkable toe to finger transplant. Byars was a most thoroughly ambidextrous surgeon. He presented a paper on skin grafts and flaps in 1944. In 1947 he described his extensive experience in the reconstruction of the mandible following head and neck surgery. These two men, Brown and Byars, brought plastic surgery to its full potential as a teaching service at Barnes Hospital for the postgraduate education of plastic surgeons in the 1950s and early 1960s—a legacy of Blair.[7] Byars was the first plastic surgeon to actually serve on the Board of Regents of the American College of Surgeons.

In that same period there were papers by Truman Blocker on the application of techniques of reconstructive surgery to certain problems in general surgery; cleft palate repair by Gordon T. McCutchen; and malignant melanoma by William McCune and Gordon Letterman. In 1954 Murray Copeland described his technique for neck dissection in the treatment of cancer of the head and neck. In the following year Robert L. Payne gave a paper on the use of skin grafts in radical mastectomy and Kenneth Pickrell described the use of the gracilis muscle as a transplant to correct urinary incontinennce in male children.

Cross finger flaps was presented in 1956 by Raymond Curtis, and in that same year Eugene Bricker and Thomas Burford presented their experience with tubed pedicle grafts in reconstruction of the esophagus. Henry Royster presented his experience with malignant melanoma.

Two years later William McFee described his technique for repair when major portions of the lower lip had been resected. That same year Meredith Alrich and Lee Brown of Charlottesville, Virginia gave a paper on their experience with cancer of the tongue. In 1958 Blocker presented the studies he conducted with his colleagues on lymph flow in lower extremities of patients with chronic ulceration and edema. In 1959 Curtiz Artz and Benjamin Gaston described the exposure method of handling burns in donor sites, and 3 years later Joseph Hamilton described fascia lata free grafts in the repair of large hernias.

The Legacy of World War II and Korea, 1963–1971

Men of this era were trained in plastic surgery during World War II or the Korean conflict in centers such as Valley Forge commanded by James Barrett Brown in World War II. In this decade there were papers on the surgical treatment of extensive cancers of the mouth and pharynx by Claude C. Coleman, Jr., chronic cystic parotitis by Truman Blocker et al. Coleman presented another paper to the SSA in 1965 on pedicle flaps in reconstructive surgery of the hand. Replantation of amputated extremities was presented by G. Rainey

Williams in 1965. In 1966 Milton T. Edgerton described his method for the surgical correction of facial paralysis. In 1968 B. W. Haynes presented his work on the early excision and grafting of third-degree burns. In 1969 Erle Peacock described treatment of burned hands, and the following year, Bert Myers and Isadore Cohn presented their work on the prevention of skin sloughs in radical mastectomy. That same year Erle Peacock presented another paper, this one on transplantation of finger tips. The following year there were papers by Curtis Artz on allografts and xenografts as biologic dressings and a paper by Edward Krementz and Robert Ryan on perfusion of extremity melanoma.

Centers of excellence in plastic surgery were established in roughly this era at Johns Hopkins under the leadership of Milton T. Edgerton, at Duke by Kenneth Pickrell, at Galveston by Truman Blocker, at Chapel Hill by Erle Peacock, at the University of Pennsylvania by Henry Royster, and at Tulane by Robert Ryan. Each of these men was directly trained or partially trained by John Staige Davis, Vilray Blair, or their pupils (*e.g.*, Robert Ivy, James Barrett Brown, or Neal Owens).

The Century Completed, 1976–1986

The last decade of the first 100 years of the SSA is witness to plastic and reconstructive surgery by the use of musculocutaneous flaps, omentum, and free flap transfer by microsurgery. With these advances came the observations of the true nature of blood supply to skin and the technical refinements in instrumentation that made microsurgery possible.

Once again one can trace the influence of John Staige Davis and Vilray Blair directly to the developments of the modern era of plastic surgery. The concept of general plastic surgery championed by Davis and the idea that plastic surgery would best flourish as part of general surgery articulated so forcefully by Blair is exemplified by the papers at the SSA in the last decade of the first 100 years. Examples include the extracelomic use of omentum either as a free flap or as a transposition flap in reconstructive surgery, breast reconstruction following mastectomy for cancer, microsurgical composite tissue transplantation, muscle flaps in the treatment of the infected median sternotomy wound, free jejunal grafts to reconstruct the cervical esophagus, chest wall reconstruction, and the reconstructive surgery necessary to treat morbid complications of conservation treatment of breast cancer. These papers are examples of the prophetic insight of Vilray Papin Blair in his presidential address to the SSA in 1933 when he said, "With the exception of those dependent upon some more recently contrived instrument of precision, or some development in an extraneous science, there are few outstanding attainments in any surgical specialty not the direct outgrowth of its inheritance from the general surgeon."[8]

Acknowledgment

The author acknowledges the great help of Sue Ann Weber, R.N., in the preparation of this historical review. She was of great help in the identification of articles or discussions in the *Transactions of the Southern Surgical Association* that were pertinent to Plastic Surgery. Many thanks for your kindness.

Comment from President Sawyers

Dr. Jurkiewicz's superb presentation has described the important contributions to the specialty of plastic surgery from Fellows of the Southern Surgical Association during the past hundred years, but Josh Jurkiewicz has modestly omitted his own contributions, which have been numerous. Dr. Jurkiewicz has been a frequent contributor to the scientific program of the Southern Surgical Association. I would be remiss not to call the audience's attention to Dr. Jurkiewicz's important contributions to his specialty of plastic and reconstructive surgery. He won the Shipley award for his presentation as a new member in 1976.

Dr. Jurkiewicz's presentations:

1976 The Omentum: An Account of its Use in the Reconstruction of the Chest Wall
1979 Infected Medial Sternotomy Wound: Successful Treatment by Muscle Flaps
1980 Management of Acute Full-thickness Losses of the Abdominal Wall
1981 The Omentum: Its Use as a Free Vascularized Graft for Reconstruction of the Head and Neck
1983 Pharyngoesophageal Stricture and Fistula: Treatment by Full Jejunal Graft

Transplantation of Tissues and Organs

Review of the First 100 Years of the Southern Surgical Association

JAMES D. HARDY, M.D., F.A.C.S.*

THE INVITATION to review the transplantation papers delivered before the Southern Surgical Association (SSA) over this first century has proved to be a rewarding experience. First, it has been most interesting to note the transplantation reports given successively before our society, concomitant with the worldwide development of transplantation science. Secondly, the volume by volume examination of the *Transactions of the Southern Surgical Association* over the past 100 years has given me a far wider and deeper knowledge and appreciation of the vast dimensions and the rich history of our heritage.

A review of this type poses a variety of challenges. First, exactly what constitutes transplantation? For example, blood transfusion? Or should all papers selected involve vascular anastomoses? Certainly not. However, should routine split-thickness skin grafting be reviewed? I decided not. Clearly, there has had to be some degree of selectivity in papers included for this review, but almost all are cited or appear in the bibliography. Finally, this writer is fully aware that the papers presented before the SSA represent but a very small segment of the work being published concurrently in the field of transplantation throughout the world. Space simply has precluded my giving detailed credit and priority to the many other investigators.

Next, having perused the 100 years of SSA programs, and having assembled the pertinent articles, how should the material be handled? Should the articles be taken up within rigid chronological order? Or should the papers be grouped under organ systems, with the first paper in each established field of transplantation—immunology, storage, endocrinology, kidney, heart, *etc.*—highlighted?

From the University of Mississippi Medical Center and the Veterans Administration Medical Center, Jackson, Mississippi

In the end, it was elected to group the three earliest transplantation publications as a spectacular entree, but thereafter to achieve thoughtful order by grouping the pertinent papers under specific sectors of transplantation science or specific organ transplantation (Table 1).

The First Three Reports

On the Treatment of Hemorrhage by Direct Transfusion of Similar Blood

At the 1906 meeting in Baltimore, a remarkable report was given by George Crile of Cleveland, regarding the transfusion of three patients.[7] In brief, the related donor and recipient were placed head to foot, with the right arms lying side by side on an intervening table (Fig. 1). The radial artery of the donor was mobilized and divided, the distal end ligated, and the proximal end anastomosed to the central end of the divided median basilic vein of the "donee"—after "the work of Carrel, his predecessors and associates."[7] Her son was the donor for the first patient, a 54-year-old woman with long continuing melena and a red cell count of 1.2 million and 12% Hgb. There was no reaction to the transfusion.

The first donor for the second patient, a man post-nephrotomy for stones, was a brother. Again, there was no transfusion reaction. The physical appearance and blood laboratory values of the recipient improved dramatically, and a nephrectomy was performed. However, subsequent hemorrhage required direct transfusion from another brother. This time, in contrast, the donee complained of precordial distress and protested loudly that he felt sick. His breathing was markedly increased. "Later, he was seized with a chill accompanied by considerable circulatory disturbance."[7] The patient gradu-

ally regained his composure and was much improved. There was no further bleeding and the patient recovered.

The third patient had anemia associated with gallbladder cancer. The patient's brother served as donor and there was no reaction. Nevertheless, after the continuous flow had been maintained for 40 minutes, the donor showed "slight evidence of fainting" and the transfusion was terminated.[7] [The Riva-Rocci sphygmomanometer had been brought to the United States by Harvey Cushing in 1901. Crile knew the instrument but it was not used here.] Interestingly, during the transfusion, bleeding from the patient's nose and uterus, which had been progressive, ceased.

What profound hazards had lurked, during these daring, epochal and beneficial transfusions: donor shock from unmeasured blood loss to the donee and anaphylactic transfusion reaction in the donee due to incompatible blood. Yet, Crile clearly knew that a close relative would be the best donor. [Landsteiner in Germany had presaged the ABO blood groups in 1900, but routine matching was yet to be developed.] And one may speculate that the platelets and fresh plasma transfused may have corrected the coagulopathy and stopped the spontaneous nose and uterine bleeding in the third recipient. [Apparently, William S. Halsted had performed the first transfusion in the United States, in 1881, from himself to his sister, using a syringe.]

J. M. T. Finney of Baltimore was asked to open the discussion. He congratulated the essayist and expressed the hope that Crile would demonstrate his method on a dog before the members of the Society. He suggested that Dr. Cushing would be willing to help in making the necessary arrangements. [Cushing was then in charge of the surgical "dog lab" at Johns Hopkins.] Finney asked why a cannula could not be used between the artery and vein to simplify the procedure. Crile replied that they had tried a variety of cannulas in animals, but that the clotting problem was too great. Samuel J. Mixter of Boston believed that Crile had been too modest. Why not tranfuse prophylactically?: "We all know the terrible, uncontrollable hemorrhages that occur after operations during deep jaundice, and which, at present, in spite of giving various agents, have proved so intractable."[7] [Note the bleeding hazard of surgery in the jaundiced patient prior to the discovery of vitamin K.]

Robert T. Morris of New York asked why there had not been more hemolysis in Crile's three patients. He also noted that "in our grafting work, in transferring tissues from one animal to another, there is a well-known principle of intolerance, and this must apply with extreme force in a case where blood carried from one individual is to be taken by the blood of another individual."[7]

William H. Welch, pathologist was asked to take part in the discussion. He reviewed the history of blood transfusion, noting that "in the seventeenth century it was supposed that one of the greatest discoveries in practical medicine had been made in the transfusion of blood." As regards renal hemorrhage in one of the cases, he asked "whether Dr. Crile has had any experience in the administration of kerosene, and whether it is useful or not in these cases?"[7]

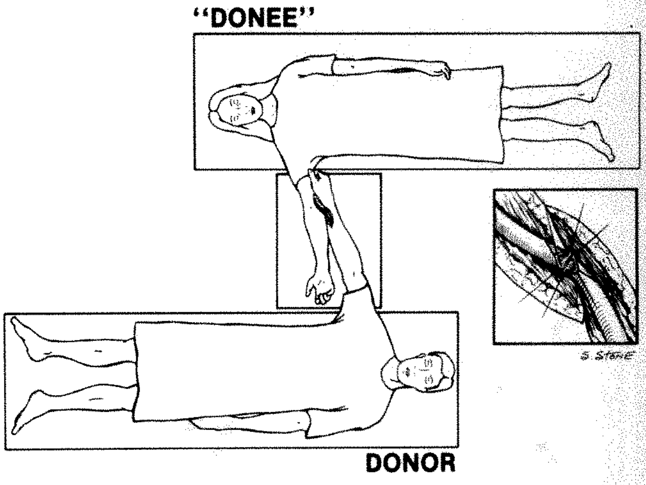

FIG. 1. Artist's conception of the positioning used by Crile for direct blood transfusion. The proximal end of the radial artery of the donor was anastomosed to the central end of the divided median basilic vein of the "donee" (Crile's designation).[7]

Report of a Case of Urethral Transplantation (1908)

At the 21st session in 1908 in St. Louis, J. D. S. Davis of Birmingham presented a preliminary report on the operation for transplanting a calf's urethra (4 inches) into a man whose perineum had sloughed.[9] Davis said, "A young calf was killed by my butchers at 4 A.M., and its entire urethra and bladder dissected out and put in cold normal salt solution and sent to the hospital to be used at 8:30 A.M. I was detained in an important emergency case and did not reach the hospital until my regular clinic hour—2 P.M., ten hours after the calf was killed."[9] "I sent two of my internes, Harris and Lanier,

to make the dissection from the calf under sterile precautions, but they did not reach the slaughter house before the butcher had removed the specimen". . . . "When I had the field ready, I passed a rigid rubber catheter (No. 30 F.) through the pendulous urethra, through the four inches of the calf's urethra, and then through the prostatic urethra into the bladder." (Fig. 2).[9] The catheter was removed on the tenth day. The suprapubic syphon drainage was discarded on this date and a No. 20 F. sound was then passed, being used daily for five times, and then every second day for six times. Twenty-one days after the operation an unsuccessful effort was made to close a fistula at the distal end, but a biopsy of the heterograft taken at that time and examined microscopically exhibited no changes. The patient was well and the fistula had closed over a year later.

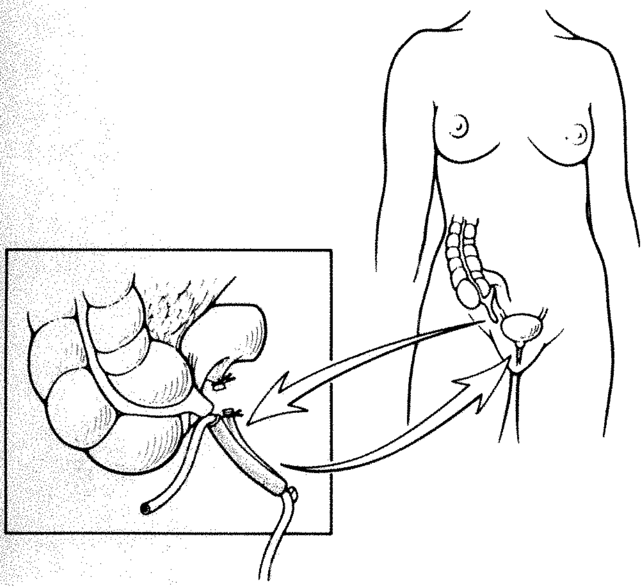

FIG. 3. Artist's conception of operative technique used by Rosser for urethral repair using appendiceal autotransplantation.[39]

One can only speculate regarding the possible survival of the heterograft, on the one hand, and on the possibility of auto-urethral mucosal generation to replace a disintegrated heterograft (xenograft), on the other hand.

Transplantation of the Appendix to Supply an Absent Urethra (1918)

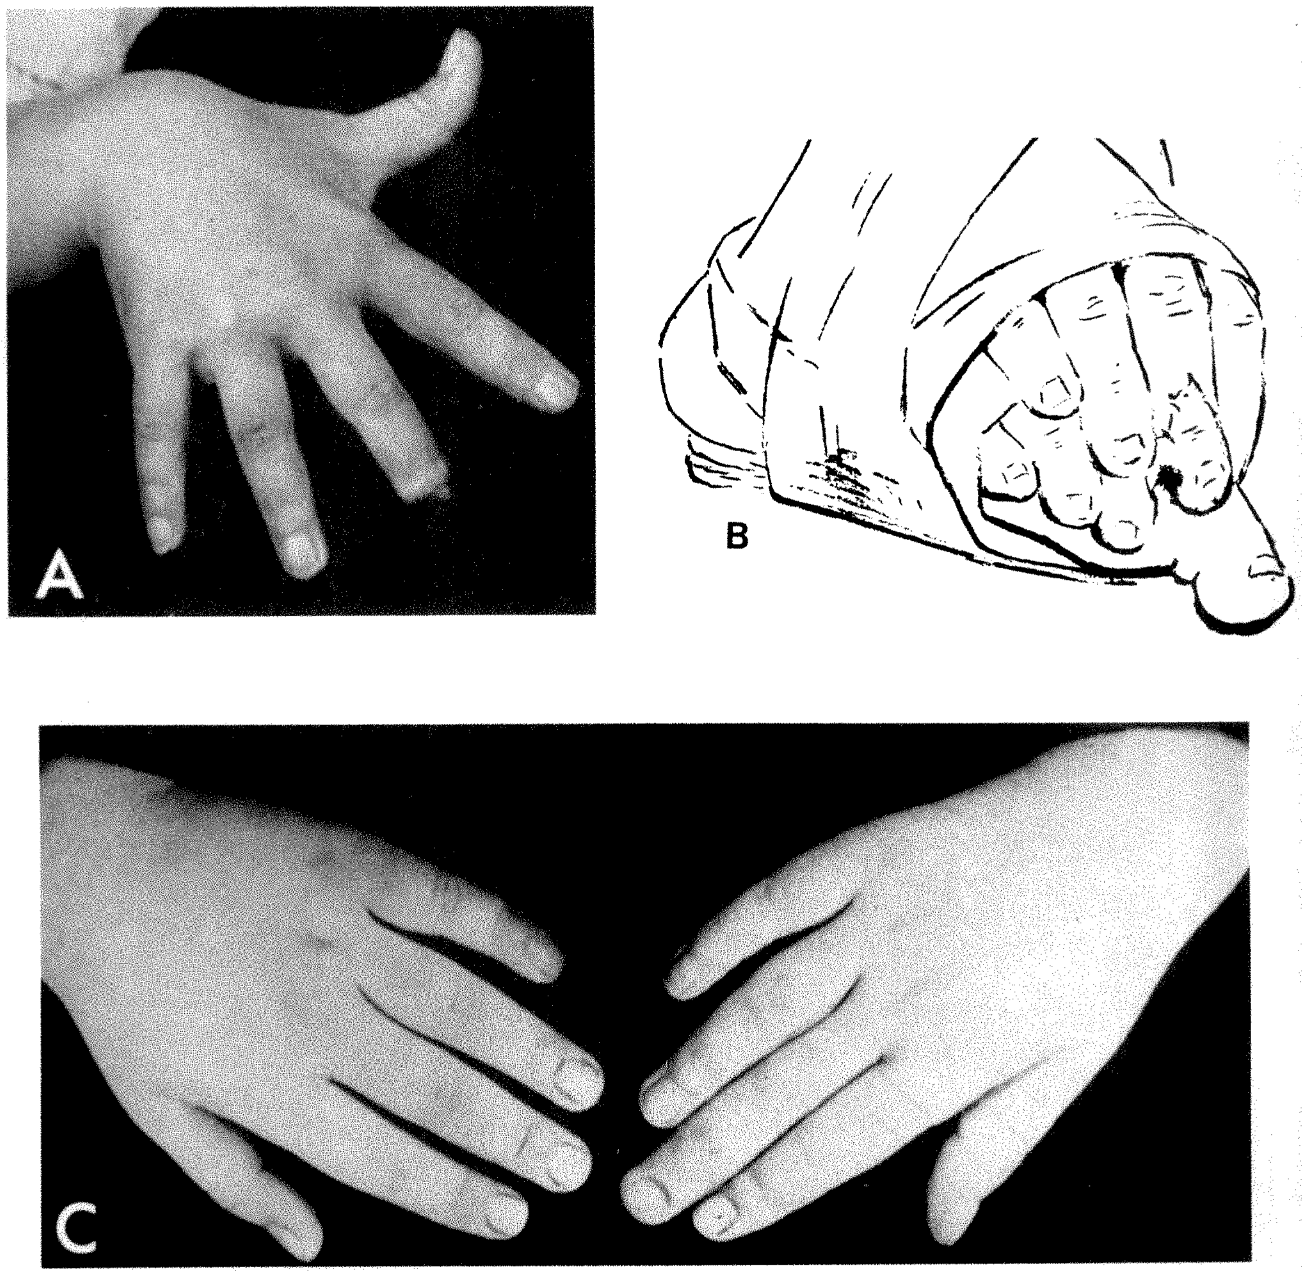
Rosser at the 31st meeting in 1918 in Baltimore, described a patient in whom her own appendix had been used to replace her urethra (Fig. 3).[39] The follow-up evaluation was only a few weeks at the time of the meeting, and the ultimate fate of the appendiceal transplant used to replace her cancerous urethra is unknown. The principal discussor was Guy LeRoy Hunner, of Baltimore, who described Hunner's ulcer of the bladder.

Orthopedic Transplantation

One of the most striking aspects of the history of transplantation in the SSA is that early on the current subspecialties were still largely within the domain of the general surgeon: urology, gynecology, and orthopedics especially. Thus, earlier in our history, papers dealing with problems in these subspecialties were commonly presented at our annual programs. And so it was with orthopedics.

At the 1912 meeting Baer presented his paper "Arthroplasty with the Aid of Animal Membrane" in which he reviewed experimental results in dogs and presented results in 100 patients, some followed for up to 8 years.[3] In brief, he used chromicized pigs' bladder as the material of "interpolation." He believed that this absorbable material, which did not disintegrate until from 60 to 100 days, preserved joint space and motion, while surrounding tissue provided a new fibrous covering to be formed on the surfaces of the joint. The pig membrane was kindly prepared "by Messrs. Johnson and Johnson."[3]

At the 1918 meeting Martin presented a paper and stated that, "probably no class of cases occurring in the recent war has offered more important and interesting problems for solution than *gunshot fractures of long bones.*"[27] The fractures were commonly complicated by sepsis and osteomyelitis, and often as well by nerve in-



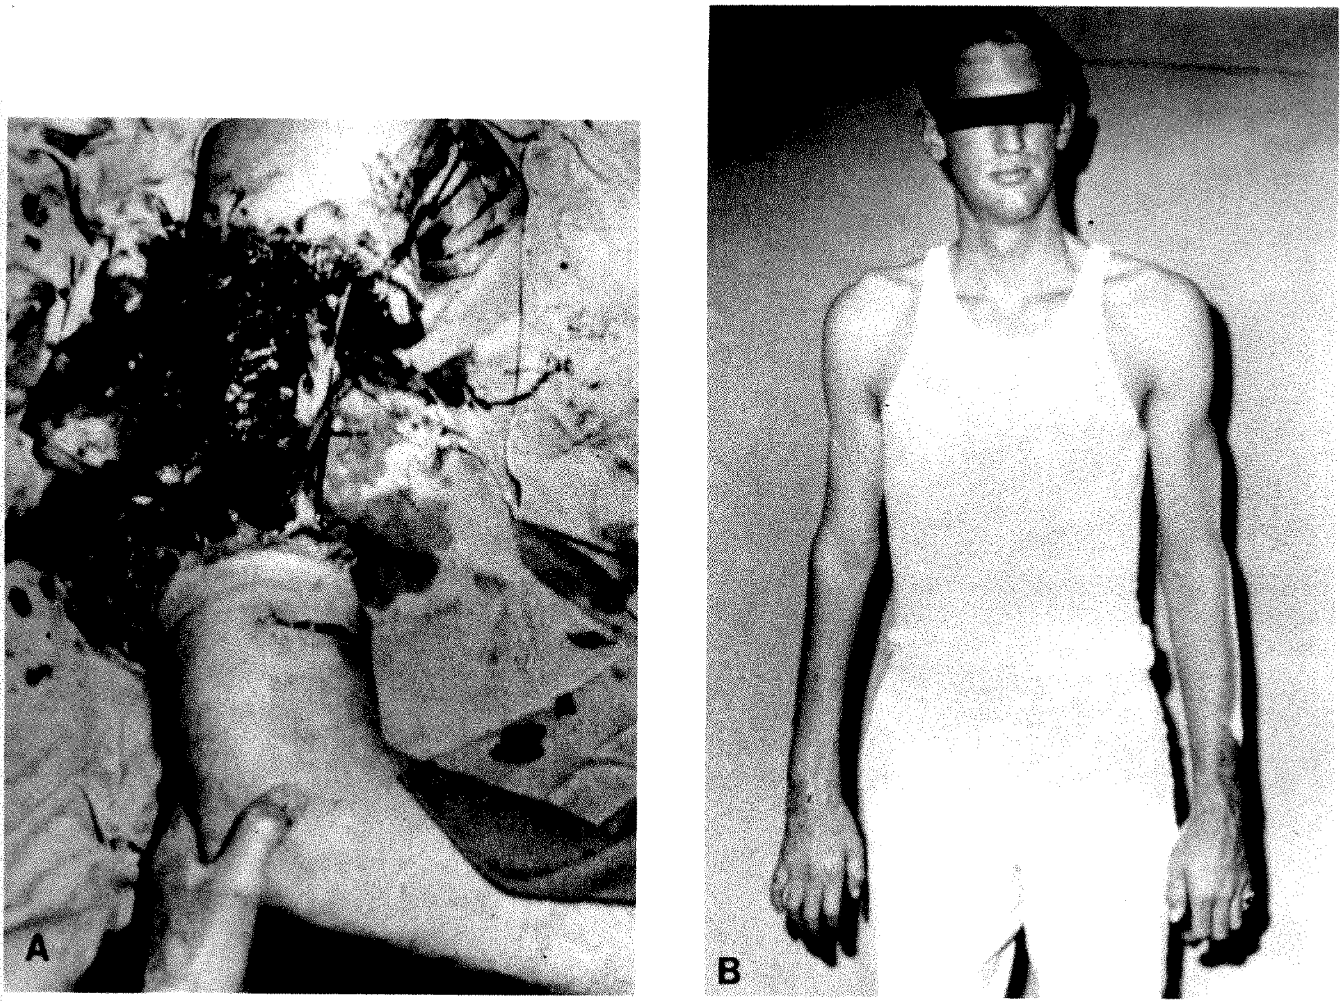
FIGS. 4A–C. *A.* Severed tip of the right middle finger. *B.* Distal phalanx of right middle finger sutured to distal phalanx of the right second toe. *C.* Excellent cosmetic result.[4]

jury, but the bone grafts were considered beneficial in most of the patients.

Another bone transplantation report was that in 1944 by Blocker and Weiss.[5] As Martin's report had dealt with his experience in World War I, Blocker and Weiss's report dealt with their experience in World War II.

The bone autotransplants did not require preservation of continuous blood supply immediately after transfer. However, now the transplant horizons began to include consideration of transplanting tissues the blood supply of which had to be preserved for success. Using the full thickness pedicle skin flap, Blair and Byars of St. Louis, at the 1939 meeting, discussed a case in which the tip of the right middle finger of a young girl had been reconstructed using the distal phalanx of the right second toe.[4] As shown in Figure 4, the cosmetic result was excellent. Peacock et al.[34] also reported their work with transplantation of fingertips at the 1970 meeting.

Even so, the aforementioned finger transplants still had not required formal vascular anastomoses. However, "shortly after midnight, on November 1, 1964, a 20-year-old white male college student was admitted to



FIGS. 5A and B. *A*. Severed right arm. *B*. Reimplanted right arm months later.[49]

the University of Oklahoma Medical Center following amputation of the right upper extremity."[49] Former president G. Rainey Williams, in collaboration with Carter, Frank, and Price, replanted the arm successfully, as shown in Figure 5.[49]

While parts of extremities had been replanted clinically previously, this case constituted a signal achievement, and in the years since then extremity replantation has become commonplace.

Endocrine Transplantation

Endocrine transplantation did not require the sophisticated use of vascular anastomoses, and hence the early endocrine studies preceded clinical transplantation of whole organs such as the kidney, lung, and heart.

Although William S. Halsted of Baltimore was never a member of the SSA, his earlier work probably was seminal in the field of endocrine autotransplantation and homotransplantation. The first mention of endocrine (here, parathyroid) transplantation (implantation) before the SSA appears to have been that of Mayo and McGrath in their paper: "the surgeon should scrupulously guard against removal or injury of the parathyroids. . . . If such a mass be accidentally removed in the course of operation it should be at once implanted beneath some part of the remaining capsule."[28]

Nonetheless, by far, our earliest and most persistent SSA endocrine transplanter was Stone[45–48] of Baltimore, whose first related paper, "Living Grafts of Endocrine Glands," was presented at the Hot Springs meeting in 1933.[48] He and his colleagues had transplanted parathyroid tissue and thyroid tissue to other sites in the same dog and to other dogs, employing many ingenious variations and gaining extended survival in some instances. They acknowledged "the general feeling among medical men that it is impossible to graft successfully living tissues from one animal to another". . . . They noted "the general feeling that this represents some antagonistic chemical action, perhaps like an allergic phenomenon because of incompatibility between the biological chemistry of the graft and of its host."[48] They also transplanted human parathyroid on two occasions in a female patient, after growing the allotransplants for a period of time in the prospective recipient's serum. Complete reversal of the patient's hypocalcemia (4.9 to 6.6 mg/dL before operation) and the relief of chronic tetany were achieved. However, the follow-up time was only 5 months. [It is well known that parathyroid allografts may survive for extended periods, although ultimately they are rejected.] Their second patient received, first, a parathyroid graft from a dog (in the axilla) and a second graft from a human. Her serum calcium level rose from 6.6 to a high of 11.5 mg/dL and all symptoms of hypocalcemia were abolished. Here again, the follow-up period was only several months.

In subsequent investigations, Stone and Kennedy implanted small thin slices of endocrine tissue from an animal of one species into one of another species (heterografts or xenografts), the tissue being contained in a "millipore filter of a pore size small enough to exclude all animal cells" (Fig. 6).[47] The gradual atrophy and disintegration of this tissue they attributed to starvation of the tissue due to ischemia. [However, as noted above, subsequent studies by others confirmed the role of graft rejection factors as well.] A principal discussor was Dunphy who cautioned against assuming that the rejection reaction had been avoided by use of the millipore filter, which excluded the ingress of host cells.

In 1963 Hardy and Langford presented a paper,[20] where at operation for total adrenalectomy for Cushing's disease, four patients had undergone transplantation of segments of slices of one of the excised adrenals to the right thigh, the implant(s) being inserted into the sartorius muscle in the last two patients. Various degrees of "takes" of these autotransplants had been confirmed by subsequent biopsy under local anesthesia. However, by the time of a subsequent report to the SSA in 1984, Hardy et al.[21] were able to document various degrees of long-term graft survival. It sometimes required years before the implants had gained sufficient parasitic blood supply and size to permit complete withdrawal of replacement therapy. However, one patient had so much growth of the implants that Cushing's disease returned and the autograft "adenomas" had to be excised under local anesthesia.

The next endocrine transplantation paper was that of Diethelm et al.[10] Sixty-one patients with chronic renal failure and secondary hyperparathyroidism had undergone total parathyroidectomy and parathyroid autografting, after the general principles previously established. Diethelm et al.[10] achieved ultimate transplant success from the parathyroid implantations into a sternocleidomastoid muscle. Some of their patients required administration of supplemental calcium after operation, but in no instance did profound hypocalcemia occur and no patient developed recurrent hyperparathyroidism.

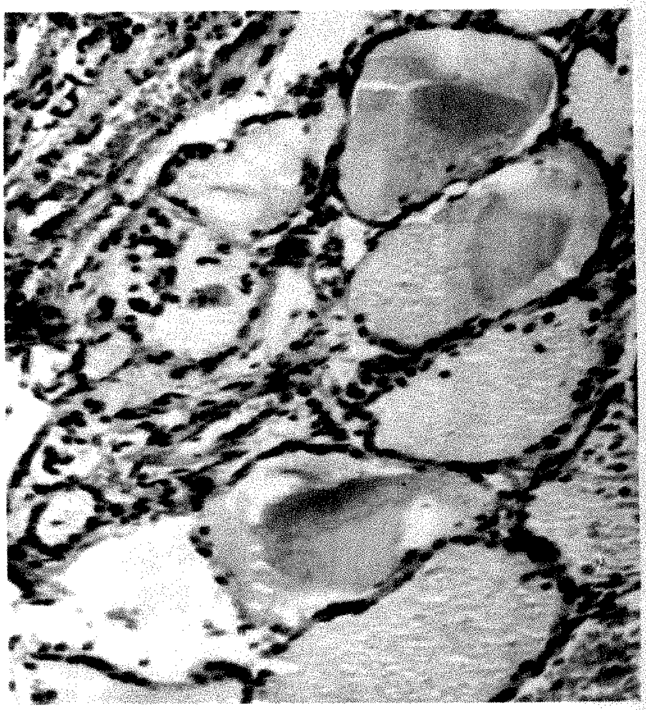


FIG. 6. Living thyroid tissue in heterologous transplant.[47]

The most recent endocrine presentation, at the 1985 meeting, was that of Rossi et al.,[40] who reported eight technically successful transplants of pancreatic segments to the femoral area, with anastomoses to the femoral artery and vein, respectively. Only one of the eight patients required insulin (at 2 years after grafting). They concluded that segmental pancreatic autotransplantation prevents or delays the onset of diabetes mellitus following total or near total pancreatic resection.

Allotransplantation Biology

The publications dealing with transplant operative technique, immunology, and organ preservation have been placed after the orthopedic and endocrine papers because (1) these two did not usually involve vascular anastomoses, and (2) transplantation science truly entered the picture only after homotransplantation (allotransplantation) was begun, usually involving whole organs that had to be preserved while being transplanted and then protected from rejection thereafter. A pivotal presentation was given by Dunphy and Jacob,[14] who emphasized the importance of separating the technical and physiologic problems of autotransplantation, on the one hand, from the additional ones created by introducing the immunologic elements of the rejection reaction, imposed by allografting or heterografting (xenografting). At the 1965 meeting Haller and Jones[18] reported on splenectomy. At that time, some kidney transplanters routinely removed the spleen ("the largest lymph node of the body"). It was already appreciated that lymphocytes (and presumably thymocytes) were key elements in the allograft rejection reaction, and thus any new information relative to splenic immunologic capabilities was potentially applicable to organ transplantation. The authors did find that splenectomy rendered the mammals represented more susceptible to infection, though splenectomy did not significantly extend skin allograft survival in mice so studied.

At the 1970 meeting Wen-Pen Liu et al.[26] detailed that perfusion with Collins' C_5 solution clearly improved organ preservation over the 48-hour period of cold storage prior to allotransplantation into nephrectomized dogs.

Another storage report was that of Starling et al.,[44] who found that methylprednisolone, a lyosomal membrane stabilizing agent, when used to pretreat the donor animal and when added to the kidney perfusate, delayed the onset of vascular resistance changes and diminished lyosomal enzyme concentrations in the perfusate.

Tissue Typing (Matching). The two reports dealing with tissue typing, both germane to the relation of tissue typing to success in renal allotransplantation, were by McDonald et al.[31] and Richie et al.[36] McDonald et al.[31] found that "in general the mixed lymphocyte culture responses parallel differences in HL-A incompatibility and appear to relate to renal allograft survival. . . . The most reliable indication of successful transplantation exists when the donor and recipient are HL-A identical serologically and no stimulation occurs in MLC's between them."[31]

Richie et al.[36] studied the role of HLA typing in cadaveric kidney transplantation. They concluded that their results "supported the concept that better results can be expected when better matched kidneys are utilized for transplantation."[36]

Skin Transplantation

In general, split thickness skin graft reports have not been included in this review of SSA publications, for such transplants had been routine and universally used for so many years. However, the report of Artz et al.,[1] "The Appraisal of Allografts and Xenografts as Biological Dressings for Wound and Burns," was of particular significance because (1) extensive full thickness burns remain so serious a problem, (2) pig skin is more readily obtained than human skin, and (3) of Artz' long and extensive experience in the management of burns. Artz et al.[1] concluded that porcine xenografts were especially useful because they are readily procurable and inexpensive. They were of value in preparation of recipient sites for grafting; in treatment of leg ulcers, decubitus ulcers, and second-degree burns; as cover for mesh grafts; and in protection of large open wounds until autografts are available. Used in the manner they described, porcine xenografts "had shown no immunological properties."[1]

Kidney Transplantation

The renal allograft has been the whole organ prototype on the immunologic basis of which other organs have been transplanted. Thus, it is not surprising that a significant number of important papers dealing with renal transplantation (Fig. 7) have been presented before the SSA. The first clinical report was that of Hardy et al.[22] at the 1966 meeting. Included were one autotransplant for ureteral injury, four cadaver donors, one living sibling donor, and five unrelated living donors.[22] This early report reflected many of the problems that attended clinical kidney allotransplantation at that time, in our university hospital as in many other hospitals throughout the world. The results were less than optimal, but they pretty much represented the general state of the art at that time. We had been obliged to use peritoneal dialysis in lieu of chronic hemodialysis, which was not initially available to us. Infection was a major problem in our patients. The paper was discussed by A. M. Lansing, who reported similar but somewhat better early results with 12 patients. He asserted that the successfully transplanted patient had a much superior quality of life than did the patient on chronic dialysis—a conclusion that was much disputed by nephrologists in those early days of clinical renal allotransplantation. Other informative presentations included work by Flanigan et al.[16] and McDonald et al.[29]

Deithelm et al.[12] reported at the 1975 meeting a retrospective analysis of 100 consecutive patients undergoing related living donor renal transplantation. Rehabilitation was good in 76% of the living patients and poor in only 4%. These same workers, in a related study presented in 1979, reviewed impaired renal function.[11]

Another carefully considered and prepared report (1979) was that of Pfaff et al.[35] HLA identical grafts showed the expected advantage compared with single haplotype grafts (93 *vs.* 74%).[35] Rohr[38] found the morphology abnormal in the post-transplant biopsy (taken at operation) in all 22 kidneys that had exhibited delayed graft function. However, four kidneys that had structural abnormalities in the procurement biopsies had functioned normally. A total of 57 cadaver allotransplants had been studied.[38]

Fish[15] utilized the technique of lymphocyte depletion

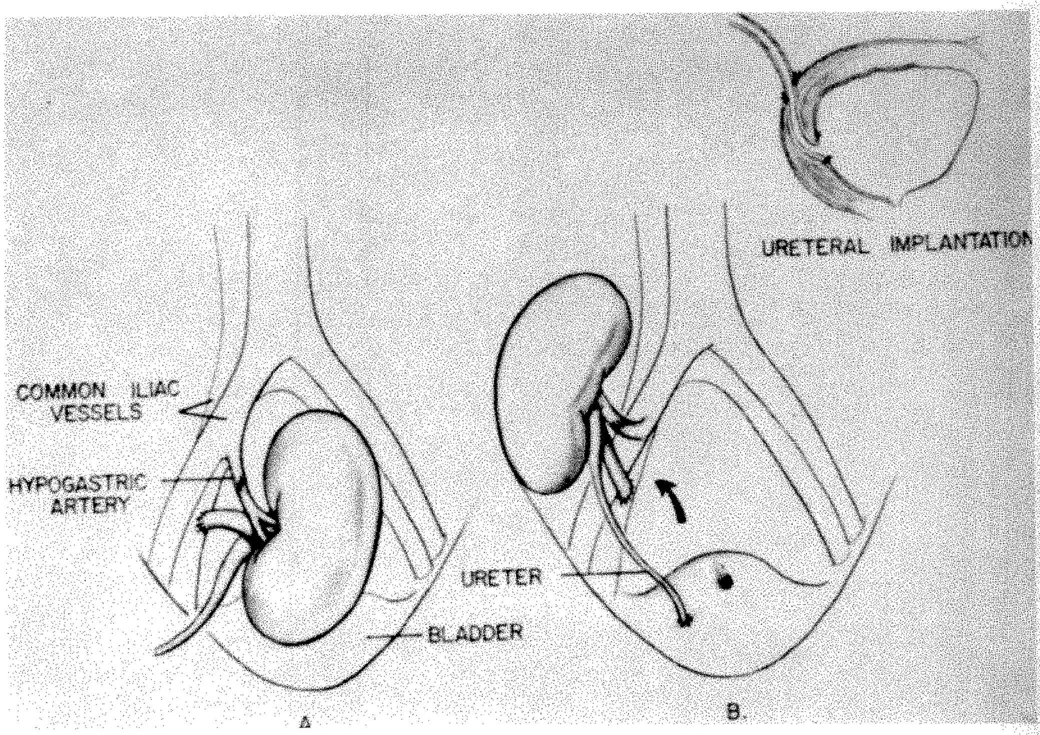

FIG. 7. Technique of kidney transplantation.[22]

by thoracic duct drainage as a method of immunosuppression in clinical kidney allotransplantation.

Richie et al.[37] studied 389 transplants performed from June 1977 to December 1981. Two-hundred fifty-three patients received cadaver kidneys and 136 patients obtained kidneys from a relative. Many factors were considered additive in permitting successful kidney allotransplantation.[37]

Biliary–Alimentary Tract Transplantation

Only two publications involved the biliary–alimentary tract. In Myers et al.[32] homografts of common bile duct and free autogenous grafts of vein, artery, and common bile duct to repair defects in the common bile duct of the dog failed in these experiments. In fact, up until now no substitute for the common bile duct has been developed, though bypasses using various elements of the stomach, duodenum, or, especially, the jejunum have served reasonably well. As yet there have been no liver transplantation publications in the Transactions.

Jejunum was transplanted clinically (Fig. 8), as reported by McDonald et al.[30] Their work extended still further the pioneer basis of the clinical autotransplantation of the organs involved, that is, kidney, jejunum, and pancreas.

Lung Transplantation

The only report dealing with lung transplantation *per se* (Fig. 9) was that of Hardy et al.[19] Studies had been performed in 215 dogs: survival on a single reimplanted lung, respiratory physiology of transplanted lungs, regeneration of lymphatics and pulmonary innervation, lung storage prior to transplantation, lung allotransplantation using a variety of immunosuppressive modalities, and presentation of a clinical case in whom lung transplantation could possibly have been life-saving and morally acceptable.[19] [The first human lung transplantation was to be performed 6 months later.]

Vascular Transplantation

The intense worldwide interest in peripheral vascular surgery, which burgeoned after the experience gained with direct repair of such injuries in the Korean War, was reflected in a number of reports before the SSA dealing with transplants as arterial substitutes. The feasibility of venous autotransplants and of arterial autografts and allografts was fully established experimentally by Carrel and Guthrie at the turn of the century, and first used clinically by Gross who in 1948 reported the successful use of aortic homografts to correct coarctation of the aorta where the involved segment was too long to permit its resection and primary end-to-end anastomosis. Fabric substitutes were under intensive study, but there was also investigation of a variety of biologic substitutes as well.

At the 1968 meeting Dale and Lewis[8] reported the use of modified bovine heterografts for arterial replacement;

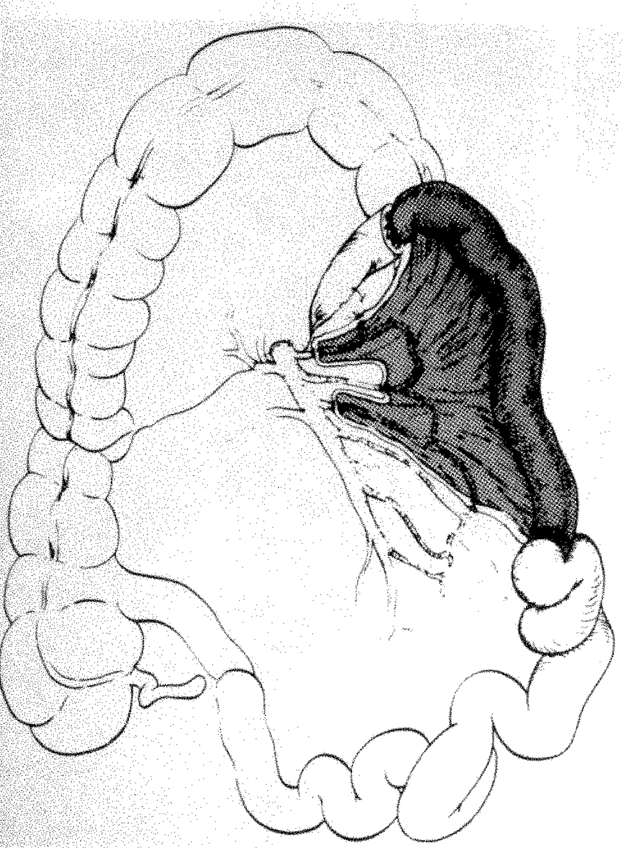

FIG. 8. Technique for excision of a segment of small intestine for transplantation.[30]

carotid arteries were removed under sterile conditions in the slaughterhouse, placed in iced water, and then treated with specified processing in the investigators' laboratory. In their review of the literature, the authors had noted that experimental and clinical results with heterografts had been attended by a high failure rate due to thrombosis, rupture, and aneurysm formation. However, their modified bovine heterograft had been used as femoral or popliteal replacement in 12 patients with favorable preliminary results. Follow-up study to 35 months had shown no aneurysm formation, and patency continued in seven of the 12 grafts placed.[8] N. Kouchoukas and J. R. Jude both discussed use of the porcine heterograft for aortic valve replacement. D. Rosenberg reported his group's use of the bovine vascular heterograft for arterial reconstruction in over 40 patients. Their results thus far were satisfactory.

Ochsner et al.[33] reported in 1970 their experience with fresh venous allografts as an arterial substitute; they had used 22 such fresh venous allografts in 22 patients. Eleven of the 22 were later shown to be occluded. The authors suggested that compatible matching within the ABO system might enhance allograft success.[33]

Microvascular Transplantation

One of the most remarkable examples of progress in transplantation has been the ever more sophisticated anastomosis of smaller and smaller blood vessels, permitting successful autotransplantation of various body tissues with immediate reestablishment of blood flow through the tissue at its new site. This has permitted repair of major body surface and deeper tissue defects.

Serafin and Georgiade[41] presented a study on microsurgical composite tissue transplantation. Since 1974, 69 patients with extensive defects had undergone reconstruction by microsurgical composite tissue transplantation. In the series, transplantation in 56 patients (81%) had been completely successful. They emphasized that healthy, well vascularized tissue could now be transferred to a distant previously irradiated area with no tissue loss.

At the 1981 meeting Jurkiewicz and Nahai[24] presented a report on the use of the omentum as a free vascularized graft for head and neck reconstruction (Fig. 10). The omentum had been so used in 18 patients, with most gratifying success.

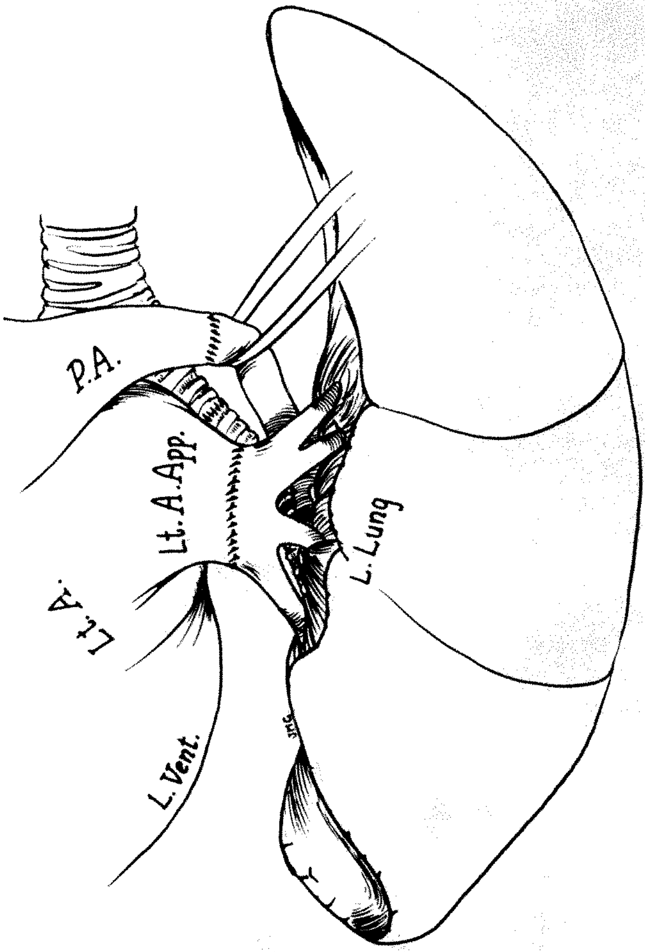

FIG. 9. Technique of lung transplantation.[19]

Transplantation Involving the Heart

The modalities of tissue transplantation involving the heart were vein autotransplants in coronary artery bypass, valve replacement with homografts (allografts) or porcine heterografts (xenografts), and total heart transplantation.

At the 1968 meeting Karp and Kirklin[25] reported on replacement of diseased aortic valves with homografts; their group was a world leader, with this extensive and successful experience with 70 aortic valve homografts.[25]

At the 1970 meeting Spencer et al.[42] reported on bypass grafting for occlusive disease of the coronary arteries. At that time this was a very substantial experience with an operation not yet fully accepted for relief of myocardial ischemia. Autografts of the saphenous vein were combined with use of the internal mammary arteries (Fig. 11). The mortality rate was 10%, and the overall success achieved was impressive.[42] Another important report by Spencer et al.[43] involved extensive data supporting their conclusions that "excellent results with porcine prostheses in the first 4–5 years" could be achieved.[43]

The first SSA report involving heart transplantation was that of Denton A. Cooley et al.[6] They had performed heart transplantation in 17 patients (Fig. 12). Their results were, at this very early stage of heart transplantation, spectacular, though most of the serious posttransplant problems germane to this field of activity at that time had been chronicled.[6] Early deaths were due to "acute cardiac rejection after one week, and one each from preexisting diseases and complications of immunosuppressive therapy, respectively."[6] Two deaths later occurred from sepsis. Three patients died at from 5 to nearly 7 months after operation from chronic cardiac rejection. [Barnard had performed the first successful clinical heart transplantation in 1967.] The paper was discussed by Hardy, who showed a motion picture of the first heart transplantation (chimpanzee) in man in 1964. W. R. Webb discussed the physiologic and immunologic considerations of heart transplantation on the basis of his long and extensive experience with experimental heart transplantation.

At the 1986 meeting Gray et al.[17] presented a report of a successful cardiac transplantation program using combined university and community resources.

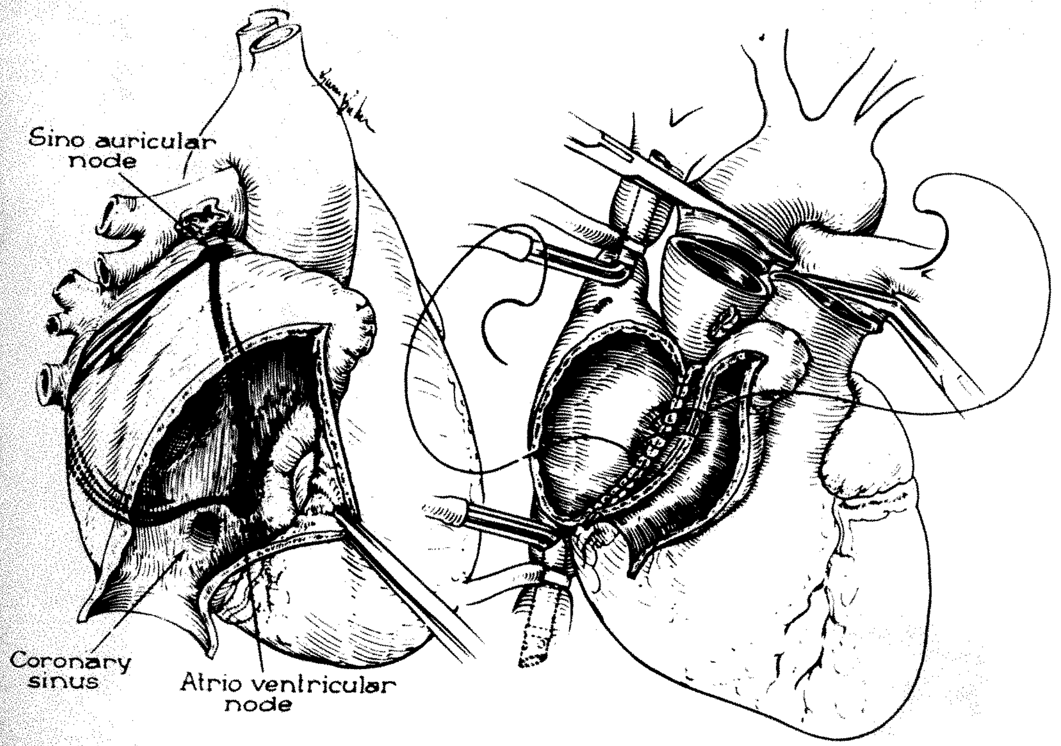

FIG. 12. Technique of heart transplantation.[6]

The Multiple Organ Transplant Program

The final paper in this review of transplantation of organs and tissues presentations before the SSA highlights the climax of cumulative experience with clinical organ transplantation during the SSA's first century. At the 1985 meeting Bahnson et al.[2] presented their experience with the development and organization of a multiple organ transplantation program. They had established in Pittsburgh possibly the foremost multiple organ transplant center in the world.

Conclusions

We now stand poised to achieve routinely successful clinical transplantation of most organs. And it has been well said that organ transplantation is the general surgeon's tomorrow. Who can doubt its vast influence on clinical surgery during the Southern Surgical Association's second century?

ANNALS OF SURGERY (ISSN 0003-4932) is published monthly by the J. B. Lippincott Company, at Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740. Business offices are located at East Washington Square, Philadelphia, PA 19105. Printed in the U.S.A. © Copyright 1988 by J. B. Lippincott Company. Second class postage paid at Hagerstown, MD, and at additional mailing offices.

Subscription information, orders, or changes of address: (exceptions listed below) Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740, or call 1-800-638-3030; in Maryland, call collect 301-824-7300. In Japan, contact Woodbell Scope Incorporated, Mansui Bldg., 9-18, Kanda Surugadai 2-chome, Chiyoda-ku, Tokyo 101, Japan. In India, Nepal, Bangladesh, and Sri Lanka, contact Universal Subscription Agency Pvt. Ltd., 101-102 Community Centre (F.F.) Saket, New Delhi-110017, India.

Annual subscription rates: U.S. $53.00 individual, $74.00 institution, Resident/Student $35.00; all other countries except Japan, $70.00 individual, $91.00 institution. Resident/Student (CAN only) $52.00. Single copies $8.00. Rates for airmail delivery available upon request. Copies will be replaced without charge if the publisher receives a request within 60 days of the mailing date in the U.S. or within 5 months in all other countries.

Postmaster: Send address changes to Annals of Surgery, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740.

ANNALS OF SURGERY GUEST REVIEWERS

January 1, 1987 to December 31, 1987

The Editorial Board of *Annals of Surgery* is very grateful to the Guest Reviewers listed below:

Dr. Onyekwere E. Akwari
Dr. Robert W. Anderson
Dr. Arthur H. Aufses, Jr.
Dr. Charles M. Balch
Dr. Robert W. Beart, Jr.
Dr. John J. Bergan
Dr. R. Randal Bollinger
Dr. Gregory B. Bulkley
Dr. John L. Cameron
Dr. David L. Dunn
Dr. Ben Eiseman
Dr. Harry A. Gallis
Dr. Gregory S. Georgiade
Dr. John P. Grant
Dr. Robert J. Herfkens
Dr. Larry H. Hollier
Dr. J. Dirk Iglehart
Dr. Robert H. Jones
Dr. Ronald C. Jones
Dr. Paul H. Jordan, Jr.
Dr. Timothy J. Kinsella
Dr. Martin S. Litwin
Dr. H. Kim Lyerly
Dr. Kenneth L. Mattox
Dr. Richard L. McCann
Dr. William C. Meyers
Dr. Joseph A. Moylan
Dr. David L. Nahrwold
Dr. Francis C. Nance
Dr. Ronald L. Nichols
Dr. Malcolm O. Perry
Dr. Richard M. Peters
Dr. John M. Porter
Dr. Leonard R. Prosnitz
Dr. Basil A. Pruitt, Jr.
Dr. Kenneth P. Ramming
Dr. John H. C. Ranson
Dr. Mark M. Ravitch
Dr. Joseph G. Reves
Dr. Layton F. Rikkers
Dr. Bradley M. Rodgers
Dr. Wendell F. Rosse
Dr. Donald Silver
Dr. Richard L. Simmons
Dr. Peter K. Smith
Dr. Erwin R. Thal
Dr. Donald D. Trunkey
Dr. W. Dean Warren
Dr. Andrew L. Warshaw
Dr. Walter G. Wolfe

Subject Index to Volume 207 (January–June 1988)

A

Abdomen
  adhesion formation in, factors affecting, 693
  disorders after cardiac surgery with extracorporeal circulation, 323
  trauma management, 742
Abdominoperineal resection, compared to sphincter-saving procedure in rectal cancer (*Letters*), 482
Adenomas, colorectal, large and villous, 65
Adhesion formation, factors affecting, 693
Age
  and surgical outcomes, 267
  surgical procedures after 90 years of age, 380
Alcohol intake inhibiting cholelithiasis, 641
Anastomosis
  coloanal, in low rectal carcinoma, 61
  compression device for, 245
  justa-anastomotic neointimal hyperplasia prevention, 717
Anemia, hemolytic, splenectomy in, 581
Aneurysm, abdominal aortic, and outlook after surgery, 318
Angiodysplasia, congenital, of lower extremities in children, 213
Animal studies
  atrial natriuretic factor levels after hemorrhage and resuscitation, 195
  compression anastomotic device, 245
  factors affecting adhesion formation, 693
  Hespan affecting serum and lymphatic proteins, 416
  host and tumor response to nitrogen infusion, 80
  hypothermia effects in hemorrhagic shock, 462
  lymphoid cell populations in burns, 208
  muscle proteolysis during sepsis, 399
  somatostatin effects on intestinal obstruction, 169
Anorectal malformations, results of surgery in, 219
Antibiotic use in head and neck surgery, 108
Anus, laser surgery of, 362
Aorta
  abdominal aneurysm, and outlook after surgery, 318
  thoracic, acute traumatic tear of, 699
Archives of Southern Surgical Association, collection and preservation of, 533
Atrial natriuretic factor, serum levels after hemorrhage and resuscitation, 195
Atriocaval shunt, 555

B

Back injuries, penetrating, management of, 72
Bacteremia in hemorrhagic shock, 549
Bile, secretory IgA levels in malnutrition, 635
Biliary tract
  bronchobiliary fistulas in adults, 90
  hepatic duct bifurcation resection and transhepatic stenting in sclerosing cholangitis, 614
  laser surgery of, 362
  management of common duct stones, 135
  obstruction from chronic pancreatitis, 26
  reoperation for congenital choledochal cyst, 142
Bladder, in ileovesical and ileosigmoid fistulae in Crohn's disease, 48
Blood flow
  gastric mucosal, affected by misoprostol, 327
  spinal cord stimulation affecting, in limb ischemia, 179
Blood transfusions
  and cancer recurrence, 410
  in sickle cell patients, 434
Blood volume, atrial natriuretic factor affecting, 195
Book reviews, 112, 228, 352, 480
Breast disease
  cancer
    estrogen and progesterone receptors in, 75
    laser surgery in, 360
    and patient appraisal of segmental mastectomy, 189
    prognostic indicators in, 569
    salvage surgery for recurrences of, 347
  development of treatment of, 730
  follow-up of biopsy-proven benign disease, 404
Bronchobiliary fistulas in adults, 90
Burns
  in caustic ingestions
    and esophageal stricture management in children, 590
    hypopharyngoesophageal strictures from, 439
  leucine metabolism in, 421
  lymphoid cell populations in, 208

C

Calculi
  cholelithiasis inhibition by alcohol intake, 641
  management of common duct stones, 135

Carotid occlusion diagnosis with Doppler ultrasound, 315
Caustic ingestion
  and esophageal stricture management in children, 590
  hypopharyngoesophageal strictures from, 439
Cervical cancer recurrence after blood transfusions, 410
Chest wall reconstruction in full thickness defects, 707
Cholangiocarcinoma, hilar, liver resection in, 120
Cholangitis, sclerosing
  hepatic duct bifurcation resection and transhepatic stenting in, 614
  orthotopic liver transplantation in, 21
Choledochal cyst, congenital, reoperation for, 142
Choledocholithiasis, management of, 135
Cholelithiasis, alcohol intake inhibiting, 641
Coloanal anastomosis in low rectal carcinoma, 61
Colonoscopy
  in detection of early colorectal cancer, 174
  intraoperative, 231
Colorectal tumors
  coloanal anastomosis in low rectal cancer, 61
  colonoscopic detection of early cancer, 174
  comparison of abdominoperineal and sphincter-saving resections in (*Letters*), 482
  intraoperative and external beam irradiation in, 52
  large villous adenomas, 65
  pelvic exenteration in, 670
  polyamine levels and gastrin receptors in, 662
  recurrence after blood transfusions, 410
Compression anastomotic device, 245
Condylomata, perianal, laser excision of, 363
Crohn's disease, ileosigmoid and ileovesical fistulae in, 48
Cyst, congenital choledochal, reoperation for, 142

D

Decubitus ulcer, laser excision of, 362
Dermatofibrosarcoma protuberans, Mohs surgery in, 102
Diabetes mellitus, and primary hyperparathyroidism, 430
Diagnostic-related groups, complications and comorbidity in, 305
Diclophenac, and metabolism in surgical patients, 274
Dipyridamole, and metabolism in surgical patients, 274
DNA aneuploidy, and melanoma prognosis, 455
Doppler ultrasound in diagnosis of carotid occlusion, 315
Drug-induced esophageal strictures (*Letters*), 484
Dumping syndrome, somatostatin analogue in, 155
Duodenum
  carcinoma of ampulla of Vater in siblings, 655
  villous tumors of, 234

E

Electrical stimulation of spinal cord, in limb ischemia, 179
Endoscopy
  colonoscopic detection of early colorectal cancer, 174
  in gastrointestinal laser surgery, 364
  intraoperative colonoscopy, 231
  and papillotomy in common duct stones, 135
  percutaneous gastrostomy compared to Stamm gastrostomy, 598
Endotoxemia in hemorrhagic shock, 549
Energy metabolism
  in sarcoma patients, 283
  in surgical patients, metabolic interventions affecting, 274
Enterocolitis risk factors in Hirschsprung's disease, 240
Esophagectomy in cancer, risk factors in, 148
Esophagus
  drug-induced strictures of (*Letters*), 484
  endoesophageal pull-through procedures, 446
  hypopharyngoesophageal strictures from caustic ingestions, 439
  stricture management in children, 590
Estrogen
  receptors in breast cancer, 75
  therapy with, and recurrent hepatic hemangiomas, 115
Exenteration, pelvic, in rectal cancer, 670
Exercise during intravenous refeeding, 297
Extracorporeal circulation, acute surgical abdomen after, 323

F

Fecal contamination, and adhesion formation, 693
Felty's syndrome, splenectomy in, 581
Fistulas
  bronchobiliary, 90
  ileosigmoid and ileovesical, in Crohn's disease, 48

G

Gallstone formation, alcohol intake inhibiting, 641
Gastrectomy in cancer, risk factors in, 148
Gastrin receptors in colon cancers, 662
Gastrinoma, intraoperative ultrasonic localization of, 160
Gastrointestinal tract
  bacterial translocation affected by T cells, 387
  carcinoma of ampulla of Vater in siblings, 655
  caustic hypopharyngoesophageal strictures, 439
  coloanal anastomosis in low rectal carcinoma, 61
  compression anastomotic device, 245
  endoesophageal pull through, 446
  endoscopic laser surgery, 364
  Hirschsprung's associated enterocolitis, 240
  ileosigmoid and ileovesical fistulae in Crohn's disease, 48
  intraoperative colonoscopy, 231
  intraoperative and external beam irradiation in colorectal cancer, 52
  microbial colonization of gastric tumors, 341
  oral intake after gastrojejunostomy, 14
  percutaneous endoscopic gastrostomy, 598
  polyamine levels and gastrin receptors in colon cancer, 662
  results of surgery in anorectal malformations, 219
  risk factors in esophagectomy or gastrectomy, 148
  somatostatin effects on intestinal obstruction, 169
  surgery of esophageal structures in children, 590
  villous colorectal adenomas, large, 65
  villous tumors of duodenum, 234
  ulcers of. *See* Peptic ulcer
Gastrojejunostomy, oral intake after, 14
Gastroscopy, percutaneous endoscopic, compared to Stamm gastrostomy, 598
Gynecologic surgeons in Southern Surgical Association, 500

H

Hand, digital ischemia in malignancies (*Letters*), 482
Head and neck surgery
  antibiotic use in, 108
  outcomes affected by age and nutrition, 267
Heart
  left ventricular dysfunction in morbid obesity, 604
  surgery of, and acute surgical abdomen after extracorporeal circulation, 323
Hemangiomas of liver, recurrent, related to estrogen therapy, 115
Hematologic disorders, splenectomy in, 581
Hemodynamic dysfunction in obesity, 604
Hemorrhagic shock. *See* Shock, hemorrhagic
Hemorrhoidectomy, laser, 362
Heparin, and adhesion formation, 693
Hespan affecting serum and lymphatic proteins, 416
Hirschsprung's disease, and risk factors for enterocolitis, 240
Histamine H-2 blockers in peptic ulcer, and incidence of perforations and bleeding, 4
Hodgkin's disease, splenectomy in, 581
Honorary Fellows of Southern Surgical Association, 509
Hydroxyethyl starch affecting serum and lymphatic proteins, 416
Hyperparathyroidism
  primary, and diabetes mellitus, 430
  secondary, reoperations for, 310
Hypersplenism, idiopathic, splenectomy in, 581
Hypertension, pulmonary, in morbid obesity, 604
Hyperthyroidism, surgical management of, 724
Hypopharyngoesophageal strictures from caustic ingestions, 439
Hypothermia, effects in canine hemorrhagic shock, 462
Hypoventilation in obesity, hemodynamic function in, 604

I

Ibuprofen, and adhesion formation, 693
Ileosigmoid and ileovesical fistulae in Crohn's disease, 48
Immunoglobulin A, secretory, biliary levels in malnutrition, 635
Infection
  endotoxemia and bacteremia in hemorrhagic shock, 549
  and microbial colonization of gastric tumors, 341
  muscle proteolysis during sepsis, 399
  septic necrosis of midline wounds, 470
  and T cell role in bacterial translocation, 387
Insulinoma, intraoperative ultrasonic localization of, 160
Ischemia
  digital, in malignancies (*Letters*), 482
  and limb salvage with *in situ* tibial bypass, 184
  lower limb, spinal cord stimulation in, 179
Islet cell tumors, intraoperative ultrasonic localization of, 160

K

Ketone bodies, and postoperative energy metabolism in muscle, 95
Kidney, cadaveric transplantation survival, 538
Klatskin tumor, liver resection in, 120

L

Laser surgery, current applications of, 355
Letters to the editor, 482
Leucine metabolism in burn patients, 421
Leukemia
  chronic lymphocytic, splenectomy in, 581
  hairy cell, splenectomy in, 581
Lithiasis. *See* Calculi
Liver
  blunt trauma of, 126
  hepatic duct bifurcation resection and transhepatic stenting in sclerosing cholangitis, 614
  laser surgery of, 361
  recurrent hemangiomas related to estrogen therapy, 115
  resection for hilar cholangiocarcinoma, 120
  transplantation of
    in malignant disease, 373
    in sclerosing cholangitis, 21
  venous injuries treated with atriocaval shunt, 555
Lung, extravascular water in acute hemorrhagic pancreatitis, 33
Lymph nodes, prophylactic dissection in melanoma (*Letters*), 483
Lymphoid cell populations in burns, 208
Lymphomas, splenectomy in, 581

M

Mastectomy, segmental, patient appraisal of, 189
Matas, Rudolph, as Renaissance Man, 494
Melanoma
  and DNA aneuploidy, 455
  prophylactic lymph node dissection in (*Letters*), 483
Merkel cell carcinoma of skin, 201
Metabolism
  interventions in surgical patients, 274
  of leucine in burn patients, 421
  muscle, postoperative, ketone bodies affecting, 95
  in sarcoma patients, 283
Misoprostol, and gastric mucosal blood flow, 327
Mohs surgery in dermatofibrosarcoma protuberans, 102
Muscle
  postoperative energy metabolism affecting by ketone bodies, 95
  proteolysis during sepsis, 399
Myeloproliferative disorders, splenectomy in, 581

N

Naloxone, and metabolism in surgical patients, 274
Necrotic tissue, and adhesion formation, 693
Neuroendocrine carcinoma of skin, 201
Neutrophil phagocytosis in trauma patients, 686
Nitrogen infusions, host and tumor response to, 80
Nutrition
  biliary secretory IgA levels in malnutrition, 635
  and exercise during intravenous refeeding, 297
  host and tumor response to nitrogen infusions, 80
  and leucine metabolism in burn patients, 421

  and oral intake after gastrojejunostomy, 14
  and surgical outcomes, 267
  and weight loss as surgical risk, 290

O

Obesity, hemodynamic dysfunction in, 604
Oncology research, surgical, status report on, 262
Opsonic capacity of serum in trauma patients, 686

P

Pancreas
  cancer of, intraoperative radiotherapy in, 648
  intraoperative ultrasonic localization of islet cell tumors, 160
  laser surgery of, 361
Pancreatectomy, complications of, 39
Pancreaticogastrostomy after pancreatoduodenectomy, 253
Pancreatitis
  acute hemorrhagic, lung water in, 33
  in childhood, 257
  chronic, biliary obstruction in, 26
Parathyroid disorders. *See* Hyperparathyroidism
Parietal cell vagotomy, ulcer recurrence after, 1
Pelvic exenteration in rectal cancer, 670
Peptic ulcer
  development of treatment of, 754
  and oral intake after gastrojejunostomy, 14
  perforations and bleeding affected by histamine H-2 blockers, 4
  prevention of postoperative dumping syndrome with somatostatin analogue, 155
  recurrence after parietal cell vagotomy, 1
Peritonitis, postoperative, and septic necrosis of midline wound, 470
Phagocytosis by neutrophils, in trauma patients, 686
Photodynamic therapy, lasers in, 368
Pickwickian syndrome, hemodynamic function in, 604
Pilonidal cyst, laser excision of, 363
Plastic surgery, development of, 770
Polyamine levels in colon cancer, 662
Portal vein thrombosis, and sclerotherapy for bleeding varices, 623
Presidential Addresses of Southern Surgical Association, 517
  at 100th Anniversary Meeting, 485
Proceedings of the Southern Surgical Association, publication of, 525
Progesterone receptors in breast cancer, 75
Prostaglandin E_2, and muscle proteolysis during sepsis, 399
Prostate cancer recurrence after blood transfusions, 410
Protein
  metabolism of
    in exercise during intravenous refeeding, 297
    in sarcoma patients, 283
    in surgical patients, metabolic interventions affecting, 274
  in serum and lymph, Hespan affecting, 416
Proteolysis in muscle, during sepsis, 399
PTFE grafts, vein cuff interposition with, 717

R

Radiotherapy, intraoperative
  with external beam, in colorectal cancer, 52
  in pancreatic carcinoma, 648
Ranitidine, and metabolism in surgical patients, 274
Rectal cancer. *See* Colorectal tumors
Reoperations for secondary hyperparathyroidism, 310
Respiratory insufficiency in obesity, weight loss affecting, 604

S

Salbutamol, and metabolism in surgical patients, 274
Saphenous vein bypass, *in situ*, efficacy of, 184
Sarcoma patients, energy and protein metabolism in, 283
Sclerotherapy in variceal bleeding with portal vein thrombosis, 623
Semen analysis in varicocele in youth, 223
Shock, hemorrhagic
  and atrial natriuretic factor levels, 195
  endotoxemia and bacteremia in, 549
  and Hespan affecting serum and lymphatic proteins, 416
  hypothermia affecting, 462
Sickle cell disease, transfusion therapy in, 434
Skin
  Mohs surgery in dermatofibrosarcoma protuberans, 102
  neuroendocrine carcinoma of, 201
SMS 201-995 in prevention of postoperative dumping syndrome, 155
Somatostatin
  analogue in dumping syndrome, 155
  effects on intestinal obstruction, 169
  and metabolism in surgical patients, 274
Southern Surgical Association
  abdominal trauma management, 742
  collection and preservation of archives, 533
  development of, 485
  gastroduodenal ulcer management, 754
  gynecologic surgeons in, 500
  Honorary Fellows of, 509
  plastic surgery, 770
  presidential addresses of, 517
    at 100th Anniversary Meeting, 485
  publication of proceedings, 525
  Renaissance man of, 494
  surgical management of hyperthyroidism, 726
  transplantation of tissues and organs, 776
  treatment of breast diseases, 730
Spermidine and spermine levels in colon cancers, 662
Spherocytosis, hereditary, splenectomy in, 581
Sphincter-saving procedure compared to abdominoperineal resection in rectal cancer (*Letters*), 482
Spinal cord, electrical stimulation in limb ischemia, 179
Spleen, laser surgery of, 362
Splenectomy in hematologic disorders, 581
Stab wounds, thoracoabdominal, 335
Stomach
  cancer of
    microbial colonization of, 341
    postoperative complications and mortality in, 7
  delayed emptying after gastrojejunostomy, 14
  laser surgery of, 360

  mucosal blood flow affected by misoprostol, 327
  percutaneous endoscopic gastrostomy, 598
  surgery for obesity, hemodynamic effects of, 604
Superoxide dismutase, and adhesion formation, 693
Surgical oncology research, status report on, 262

T

T cells, role in bacterial translocation, 387
Testicular function in varicocele in youth, 223
Thoracic wall reconstruction in full thickness defects, 707
Thoracoabdominal stab wounds, 335
Thrombocytopenic purpura, splenectomy in, 581
Thrombosis of portal vein, and sclerotherapy for bleeding varices, 623
Thyrotoxicosis, surgical management of, 724
Tibial bypass, *in situ*, efficacy of, 184
Transactions of the Southern Surgical Association, publication of, 525
Transfusions
  and cancer recurrence, 410
  in sickle cell patients, 434
Transplantations
  historical aspects of, 776
  liver
    in malignant disease, 373
    in sclerosing cholangitis, 21
  renal cadaveric, survival of, 538
Transport facilities, and survival in multisystem trauma, 679
Trauma
  abdominal, 742
  acute aortic tear, 699
  atriocaval shunt in, 555
  of liver, blunt, 126
  multisystem, survival in, 679
  neutrophil phagocytosis in, 686
  penetrating injuries of back, 72
  and sepsis in shock, 549
  thoracoabdominal stab wounds, 335
Tumors. *See specific anatomic sites of tumors*

U

Ulcer
  decubitus, laser excision of, 362
  peptic. *See* Peptic ulcer
Ultrasound, and Doppler diagnosis of carotid occlusion, 315

V

Vagotomy, parietal cell, ulcer recurrence after, 1
Variceal bleeding in portal vein thrombosis, sclerotherapy in, 623
Varicocele in youths, 223
Vasculature
  atriocaval shunt, 555
  carotid occlusion diagnosis with Doppler ultrasound, 315
  efficacy of *in situ* saphenous vein bypass, 184
  juxta-anastomotic neointimal hyperplasia prevention, 717
  outlook after abdominal aortic aneurysm resection, 318
  venous malformations in children, 213
Vaterian cancer in siblings, 655
Vein cuff interposition preventing juxta-anastomic neointimal hyperplasia, 717
Venous malformations of lower extremities, in children, 213

W

Weight loss
  and surgical risk, 290
  surgically induced, hemodynamic effects of, 604

CLASSIFIED AD SECTION

Classified advertising is avabilable in **ANNALS OF SURGERY** for those recruiting personnel or interested in obtaining positions. Display space is available for those desiring greater visibility or more space for their message.

Classified ad copy, like other advertising copy, will be reviewed for approval prior to publication.

Classified Rates: $9.00 per line or fraction of line. The average line will be 62 characters.

Box Numbers: Replies may be directed via Box # to J.B. Lippincott Company, at an extra charge per insertion of $6.50 to cover handling costs in forwarding such replies to the advertiser.

How to Order: Send typewritten text copy for the ad with remittance in full to:

ANNALS OF SURGERY
c/o J.B. Lippincott Company
Attn: Classified Advertising Dept. B
East Washington Square
Philadelphia, Pa. 19105
(215) 238-4215

Deadline: Copy received by the 15th of month will run in the second following month's issue, e.g. November 15th for January issue. Ads received after the 15th will run in the next available issue.

ALL SURGICAL SPECIALTIES, NATIONWIDE. Excellent Quality of Life and Compensation. **Dr. Len Goodman, SMA, P.O. Box 25786, Charlotte, NC 28229. 704-536-2527.**

BC/BE General Surgeon to associate with two active internists in NE Wisconsin. New clinic and modern hospital with state of the art ICU. **Box ANN6B, J. B. Lippincott Company, East Washington Square, Philadelphia, PA 19105.**

BC/BE General Surgeon: Twenty-Seven physician multispecialty group in Tulsa, Oklahoma is seeking a qualified M.D. to accept the second General Surgery position within the group. A highly competitive guaranteed salary and benefits are offered, as well as a stimulating professional environment. Availability can be any time prior to July 1989. Interested parties should address a curriculum vitae to: **C. B. Rebsamen, M.D., Medical Director, Medical Care Associates of Tulsa, 7912 East 31st Court, Suite 302, Tulsa, Oklahoma 74145.**

Chairman, General Surgery Department—San Bernardino County Medical Center is seeking a new Chairman of Dept. of General Surgery. Individual will have major clinical and academic responsibilities at SBCMC and must qualify for academic appointment at Loma Linda University School of Medicine. Inquiries should be accompanied by curriculum vitaes and addressed to: **M. Kenneth Mudge, M.D., Chairperson, Dept. of General Surgery Search Committee, c/o Medical Director's Office, Rm. 101, San Bernardino County Medical Center, 780 E. Gilbert St., San Bernardino, CA 92404.** Equal opportunity employer.

Chief, Surgical Service—Veterans Administration Medical Center, Albuquerque, NM and University of New Mexico School of Medicine are seeking an individual to lead active clinical, teaching and research programs for undergraduates and residents in General, Thoracic, Plastic, Urologic and Orthopaedic Surgery. Individual will have major clinical and academic responsibilities and must have experience and accomplishments to qualify for senior academic appointment in the Department of Surgery, University of New Mexico, School of Medicine. Inquiries should be accompanied by resume and addressed to **Donald E. Fry, M.D., Chairman, Dept. of Surgery, c/o Chief of Staff, VA Medical Center, 2100 Ridgecrest Drive S.E., Albuquerque, New Mexico 87108.** VA Medical Center, Albuquerque is an equal opportunity employer.

GENERAL SURGEON—(BC/BE) Excellent opportunity to join a growing multispecialty group. We are situated 4 miles from the coast, and 30 miles from downtown San Diego. We offer an attractive salary and benefit package with an opportunity to achieve partnership status. Please send C.V. to: **Ralph Hesler, M.D., Cassidy Medical Group, 145 Thunder Drive, Vista, California 92083.**

GENERAL SURGEON—BE/BC, U.S. trained to join large multispecialty group of independent practitioners in Southeastern Massachusetts. Send CV to **Eileen F. Lynch, Suite M7, 235 Hanover Street, Fall River, MA 02720.**

GENERAL SURGEON—BC/CE with interest in peripheral vascular surgery and noninvasive lab to join two busy general surgeons in medium size midwestern city. Needed by July, 1989. Close to metropolitan area and two university medical centers. Excellent hospital facilities with young, progressive medical staff. Benefits and salary leading to partnership opportunity. Send CV to: **President's Office, Memorial Hospital, 450 E. 23rd, Fremont, Nebraska 68025.**

GENERAL SURGEON: Metropolitan North Carolina. Four person surgical group seeks Board Certified/Board Eligible M.D., University training and recent residency preferred. Reply to **Box ANN6A, J. B. Lippincott Company, East Washington Square, Philadelphia, PA 19105.**

GENERAL SURGEONS—Newly established prepaid group practice desires to begin offering general surgery services. Looking for general surgeons interested in establishing and building a department. Physicians must be from high quality residency programs or have significant practice experience. Positions available immediately and for 1989. Address CV to: **Phyllis M. Kline, Physician Recruitment Coordinator-ANS, Carolina Permanente Medical Group, P.A., 3120 Highwoods Blvd., Raleigh, N.C. 27604-1018.**

Thoracic Surgeon experienced in adult cardiac, general thoracic and peripheral vascular surgery is needed to join 195 physician multispecialty prepaid group in Hawaii. Board certified associate. Excellent fringe benefits. Malpractice paid. Please direct curriculum vitae: **Hawaii Permanente Medical Group, Inc., 3288 Moanalua Road, Honolulu, HI 96819.** An Equal Opportunity Employer.

12196
(518) 674-3109

Made of #18 French biocompatable silicone for minimum trauma without sacrificing efficiency of performance.

* Send for reprints documenting results from independent clinical centers.

CASE # 24 **AGE:** 55 **SEX:** FEMALE

DIAGNOSIS: CECAL CARCINOMA

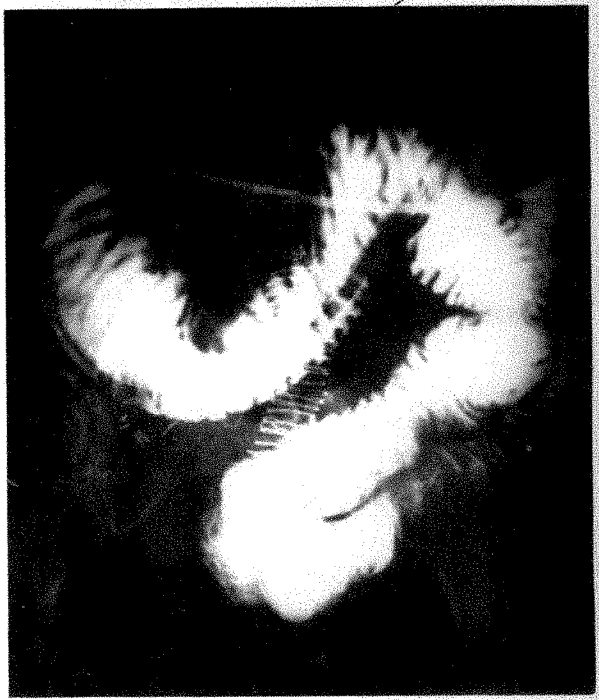
SYMPTOMS: ANEMIA (Hg 6 gm/dl)

OPERATION: RIGHT HEMICOLECTOMY & GASTROSTOMY

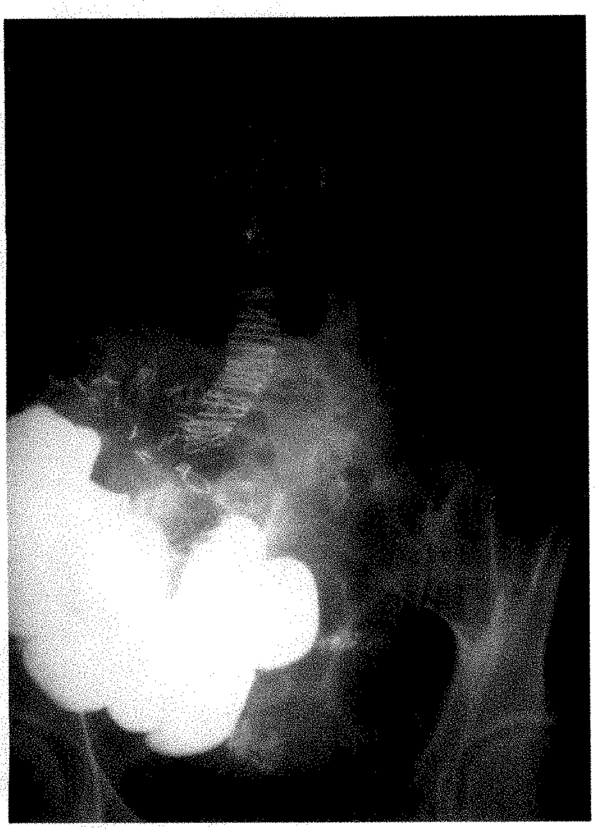
The patient had a right hemicolectomy with stapled (U.S. Surgical Corp) anastomosis and fascia closure and a MOSS® gastrostomy tube. The stomach and proximal duodenum were aspirated, with immediate simultaneous feeding into the distal duodenum.

Barium feeding 5 hours postop documented adequate motility. The deliberate excess was totally removed. No contrast (i.e.: excess feeding) escaped efficient aspiration within the proximal duodenum, to reflux into the stomach. (Figure A) Serial motility study showed barium had traversed the anastomosis and colon, and already was exiting in a spontaneous bowel movement by 21 hours postop. (Figure C)

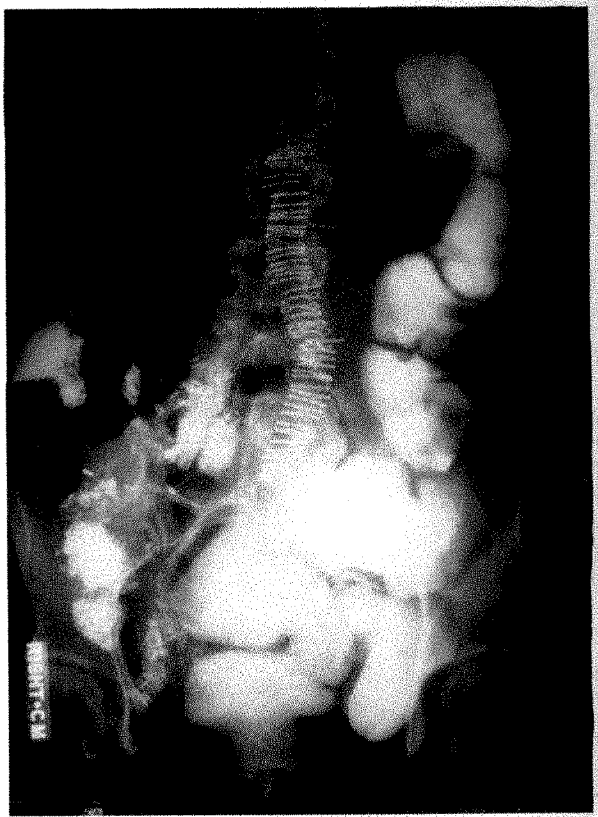
She received 300 ml/hr of Vivonex TEN (Norwich Eaton Pharm), absorbed 5,000 kcal the initial 20 hours, and then tolerated a general diet. She was the 4th patient discharged uneventfully 24 hours after bowel resection and reanastomosis.



A. Study @ 5 minutes (5 hours postop).
Note efficient removal of all excess barium, with none reaching the stomach.



B. Motility @ 4 hours (9 hours postop).
All barium is within the ileum.



C. Motility @ 16 hours (21 hours postop).
Barium is exiting in a spontaneous bowel movement.

(hydrocortisone acetate 1%, pramoxine HCl 1%)

The one with an anesthetic!

Brief Summary: Please see package insert for full prescribing information.
INDICATIONS AND USAGE: Topical corticosteroids are indicated for the relief of the inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses.
CONTRAINDICATIONS: Topical corticosteroids are contraindicated in those patients with a history of hypersensitivity to any of the components of the preparation.
PRECAUTIONS: ***General:*** Systemic absorption of topical corticosteroids has produced reversible hypothalamic-pituitary-adrenal (HPA) axis suppression, manifestations of Cushing's syndrome, hyperglycemia and glucosuria in some patients. Conditions which augment systemic absorption include the applications of the more potent steroids, use over large surface areas, prolonged use and the addition of occlusive dressings. Therefore, patients receiving a large dose of a potent topical steroid applied to a large surface area and under an occlusive dressing should be evaluated periodically for evidence of HPA axis suppression by using the urinary free cortisol and ACTH stimulation tests. If HPA axis suppression is noted, an attempt should be made to withdraw the drug, to reduce the frequency of application, or to substitute a less potent steroid. Recovery of HPA axis function is generally prompt and complete upon discontinuation of the drug. Infrequently, signs and symptoms of steroid withdrawal may occur, requiring supplemental systemic corticosteroids. Children may absorb proportionally larger amounts of topical corticosteroids and thus be more susceptible to systemic toxicity. (See PRECAUTIONS—Pediatric Use.) If irritation develops, topical corticosteroids should be discontinued and appropriate therapy instituted. In the presence of dermatological infections, the use of an appropriate antifungal or antibacterial agent should be instituted. If a favorable response does not occur promptly, the corticosteroid should be discontinued until the infection has been adequately controlled.
Information for the Patient: Patients using topical corticosteroids should receive the following information and instructions: 1. This medication is to be used as directed by the physician. It is for external use only. Avoid contact with the eyes. 2. Patients should be advised not to use this medication for any disorder other than for which it has been prescribed. 3. The treated skin area should not be bandaged or otherwise covered or wrapped as to be occlusive unless directed by the physician. 4. Patients should report any signs of local adverse reactions especially under occlusive dressing. 5. Parents of pediatric patients should be advised not to use tight-fitting diapers or plastic pants on a child being treated in the diaper area, as these garments may constitute occlusive dressings.
Laboratory Test: The following test may be helpful in evaluating the HPA axis suppression: ACTH stimulation test
Carcinogenesis, Mutagenesis and Impairment of Fertility: Long-term animal studies have not been performed to evaluate the carcinogenic potential or the effect on fertility of topical corticosteroids. Studies to determine mutagenicity with prednisolone and hydrocortisone have revealed negative results.
Pregnancy Category C: Corticosteroids are generally teratogenic in laboratory animals when administered systemically at relatively low dosage levels. The more potent corticosteroids have been shown to be teratogenic after dermal application in laboratory animals. There are no adequate and well-controlled studies in pregnant women of teratogenic effects from topically applied corticosteroids. Therefore, topical corticosteroids should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus. Drugs of this class should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.
Nursing Mothers: It is not known whether topical administration of corticosteroids could result in sufficient systemic absorption to produce detectable quantities in breast milk. Systemically administered corticosteroids are secreted into breast milk in quantities NOT likely to have a deleterious effect on the infant. Nevertheless, caution should be exercised when any topical corticosteroids are administered to a nursing woman.
Pediatric Use: Pediatric patients may demonstrate greater susceptibility to topical corticosteroid-induced HPA axis suppression and Cushing's syndrome than mature patients because of a larger skin surface area to body weight ratio. Hypothalamic-pituitary-adrenal (HPA) axis suppression, Cushing's syndrome and intracranial hypertension have been reported in children receiving topical corticosteroids. Manifestations of adrenal suppression in children include linear growth retardation, delayed weight gain, low plasma cortisol levels, and absence of response to ACTH stimulation. Manifestations of intracranial hypertension include bulging fontanelles, headaches and bilateral papilledema. Administration of topical corticosteroids to children should be limited to the least amount compatible with an effective therapeutic regimen. Chronic corticosteroid therapy may interfere with the growth and development of children.
ADVERSE REACTIONS: The following local adverse reactions are reported infrequently with topical corticosteroids, but may occur more frequently with the use of occlusive dressings. These reactions are listed in an approximately decreasing order of occurrence: burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, hypopigmentation, perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, miliaria.
OVERDOSAGE: Topically applied corticosteroids can be absorbed in sufficient amounts to produce systemic effects. (See PRECAUTIONS.)
DOSAGE AND ADMINISTRATION: Topical corticosteroids are generally applied to the affected area as a thin film three or four times daily depending on the severity of the condition. Occlusive dressings may be used for the management of psoriasis or recalcitrant conditions. If an infection develops, the use of occlusive dressings should be discontinued and appropriate antimicrobial therapy instituted.
HOW SUPPLIED: 1 oz. tube with rectal applicator.
CAUTION: Federal law prohibits dispensing without prescription.

Notice to Contributors and Subscribers

ANNALS OF SURGERY is a monthly journal which considers for publication original articles in the field of surgery. It is the oldest continuously published journal in the English language solely devoted to the surgical sciences. The Editorial Board considers only papers judged to offer significant contributions to the advancement of surgical knowledge.

CONTRIBUTIONS. Four typed copies of the manuscript and four copies of the illustrations should be sent prepaid to the Chairman of the Editorial Board of Annals of Surgery.

David C. Sabiston, Jr., M.D.
Annals of Surgery
Department of Surgery
Duke University Medical Center
Durham, North Carolina 27710

Annals of Surgery has joined a number of other leading Medical Journals which endorse the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals." These Requirements were established by an agreement among a number of Editors of Clinical Journals in the United States, Canada and the United Kingdom. The Criteria for preparation of manuscripts are as follows:

SUMMARY OF REQUIREMENTS

Type manuscript double spaced, including title page, abstract, text, acknowledgments, references, tables, and legends.

Each manuscript component should begin on a new page, in this sequence:

Title page
Abstract and key words
Text
Acknowledgments
References
Tables: each table, complete with title and footnotes, on a separate page
Legends for illustrations

Illustrations must be good quality, unmounted glossy prints usually 12.7 by 17.3 cm (5 by 7 in.) but no larger than 20.3 by 25.4 cm (8 by 10 in.).

Submit the required number of copies of manuscript and figures (*see* journal's instructions) in heavy-paper envelope. Submitted manuscript should be accompanied by covering letter, as described under "Submission of Manuscripts," and permissions to reproduce previously published materials or to use illustrations that may identify subjects.

Follow journal's instructions for transfer of copyright.

Authors should keep copies of everything submitted.

PREPARATION OF MANUSCRIPT

Type manuscript on white bond paper, 20.3 by 26.7 cm or 21.6 by 27.9 cm (8 by 10½ in. or 8½ by 11 in.) or ISO A4 (212 by 297 mm) with margins of at least 2.5 cm (1 in.). Use double spacing throughout, including title page, abstract, text, acknowledgments, references, tables, and legends for illustrations. Begin each of the following sections on separate pages: title page, abstract and key words, text, acknowledgments, references, individual tables, and legends. Number pages consecutively, beginning with the title page. Type the page number in the upper right-hand corner of each page.

Manuscripts will be reviewed for possible publication with the understanding that they are being submitted to one journal at a time and have not been published, simultaneously submitted, or already accepted for publication elsewhere. This does not preclude consideration of a manuscript that has been rejected by another journal or of a complete report that follows publication of preliminary findings elsewhere, usually in the form of an abstract. Copies of any possibly duplicative published material should be submitted with the manuscript that is being sent for consideration.

TITLE PAGE

The title page should contain [1] the title of the article, which should be concise but informative; [2] a short running head or footline of no more than 40 characters (count letters and spaces) placed at the foot of the title page and identified; [3] first name, middle initial, and last name of each author, with highest academic degree(s); [4] name of department(s) and institution(s) to which the work should be attributed; [5] disclaimers, if any; [6] name and address of author responsible for correspondence about the manuscript; [7] name and address of author to whom requests for reprints should be addressed, or statement that reprints will not be available from the author; [8] the source(s) of support in the form of grants, equipment, drugs, or all of these.

ABSTRACT AND KEY WORDS

The second page should carry an abstract of not more than 150 words. The abstract should state the purposes of the study or investigation, basic procedures (study subjects or experimental animals and observational and analytic methods), main findings (give specific data and their statistical significance, if possible), and the principal conclusions. Emphasize new and important aspects of the study or observations. Use only approved abbreviations (*see* list of Commonly Used Approved Abbreviations elsewhere in this document).

Key (indexing) terms: Below the abstract, provide and identify as such, three to 10 key words or short phrases that will assist indexers in cross-indexing your article and that may be published with the abstract. Use terms from the Medical Subject Headings list from *Index Medicus* whenever possible.

TEXT

The text of observational and experimental articles is usually—but not necessarily—divided into sections with the headings Introduction, Methods, Results, and Discussion. Long articles may need subheadings within some sections to clarify their content, especially the Results and Discussion sections. Other types of articles such as case reports, reviews, and editorials are likely to need other formats, and authors should consult individual journals for further guidance.

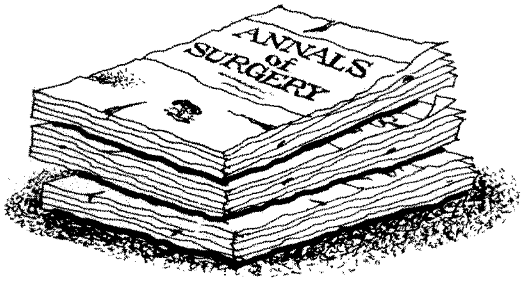
Introduction: Clearly state the *purpose* of the article. Summarize the rationale for the study or observation. Give only strictly pertinent references, and do not review the subject extensively.

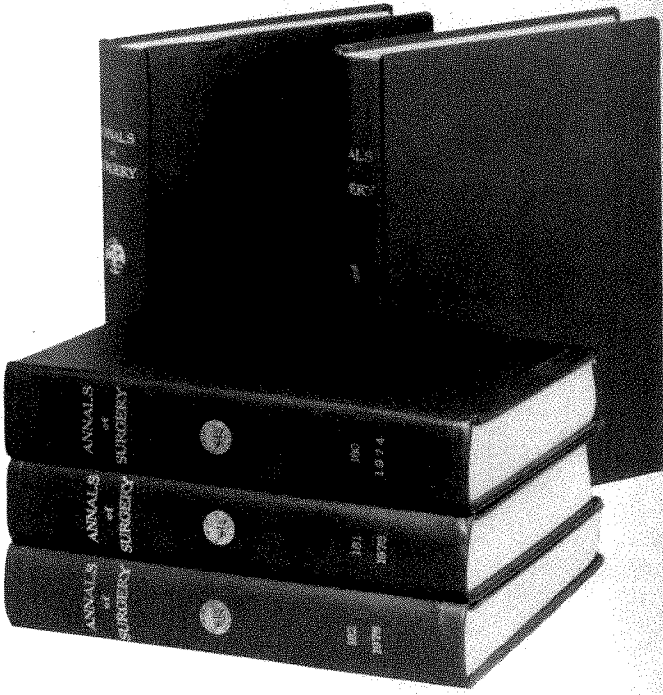
ew for 1988

For your professional library

Bound volumes of

Annals of Surgery





Long after your personal copies of ANNALS OF SURGERY have been read, shared with your office staff, used up and worn out, you can have instant access to the unique and valuable information in back issues of this distinguished journal by ordering bound volumes.

Your bound volumes give you a permanent and comprehensive reference for changes and advances in your specialty—a source that will grow and increase in usefulness over the years. Each volume features:

- all text pages of every issue, including the complete author and title indexes
- no advertising—only professional, clinically pertinent material (a space-saver on your bookshelves)
- handsome, durable bindings in maroon buckram, with the journal name, year, and volume number imprinted in gold on the spine

No need to return your personal copies to us, or to go to the trouble and expense of having them bound locally. We over-run copies of each issue in order to have sufficient quantities on hand. But we must tell our printer how many we need, so please let us know right away.

You must be a current subscriber to take advantage of this bound volume offer.

Order your 1988 volumes today. They will be on their way to you shortly after the publication of the final volume issue.

Yes! Please send me the 1988 bound volumes of **Annals of Surgery** (65-98039/65-99047) for $54.00 U.S. ($64.00 elsewhere).

Support America's colleges. Because college is more than a place where young people are preparing for their future. It's where *America* is preparing for *its* future.

If our country's going to get smarter, stronger—and more competitive—our colleges and universities simply must become a national priority.

It's an investment we all share in. Government. Private citizens. And the business community. After all, the future of American business depends on it.

So help revitalize America's economy with a corporate gift to the college of your choice—and you'll know your company has done its part.

Give to the college of your choice.

COUNCIL FOR AID TO EDUCATION CFAE

To understand much of what we're doing with respect to cancer research, you'd need a graduate degree in microbiology or biochemistry.

But to understand how well our educational programs and service resources help both patients and their families, simply talk to one out of every 100 Americans who are part of our volunteer program. Or talk to one of the 3 million who've survived cancer.

The battle isn't over but we are winning.

Please support the American Cancer Society.

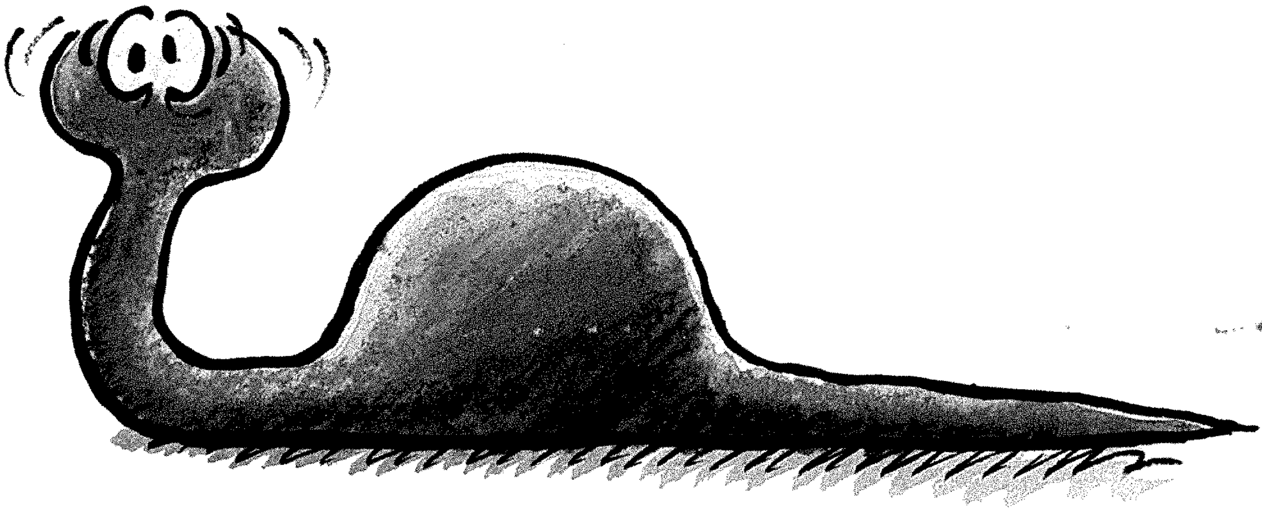
If the movement needs improvement...

Colace® or Peri-Colace®



Recommend the time-tested anticonstipants that relieve gently and reliably. Colace (docusate sodium) softens the stool and helps prevent straining . . . especially important for patients with anorectal disorders.

When laxative action is also needed, Peri-Colace (casanthranol and docusate sodium) both softens stools and stimulates peristalsis to correct constipation, usually overnight.

Colace offers you the flexibility of 50mg or 100mg capsules, syrup or liquid. Peri-Colace is available in both capsules and syrup. Recommend them with confidence for virtually all your adult and pediatric patients.

Gentle relief you've relied on for over 25 years

COLACE®
